Take an axis of coordinates, and measure off $1, 2, 3 \dots$ for values of x , upon which construct $1, 1 \cdot 2, 1 \cdot 2 \cdot 3$, &c. for the values of the ordinates of y perpendicular to x . We may thus lay down an infinite number of points in the curve, and through the first two we can draw the line $y=a_0+a_1x$ by properly assuming a_0 and a_1 . Through the first three we can draw $y=a_0+a_1x+a_2x^2$, and so on; whence through all we can draw $y=a_0+a_1x+\dots$ *ad. inf.*; or if this form should give anomalous results, we can draw $y=a_0\phi_0x+a_1\phi_1x+a_2\phi_2x+\dots$ *ad. inf.*, where ϕ_0x, ϕ_1x , &c. are functions of x to be determined. Having got this, we can now

* Our definition of the distinction between an adjective and a pronoun would be as follows: the former is a word denoting an accident absolutely considered, and which therefore is not definite until the quantity, &c. &c. is defined; and the word is used in a manner which would render a word for the *grade* of quality desirable, if it could be given. Thus when we say a green ball, meaning to describe an individual ball, the meaning is not complete until we know what degree of greenness we are speaking of. But when we speak of a lottery of green and blue balls, it matters nothing how green or how blue the balls may be, for any shades of the two contain the distinction required. The greenness and blueness being here made the distinction between nouns, are, we assert, *pronominally* used, as much as *this* or *that*.

Theory of
Pro-
babilities.

assign the value of y , corresponding to fractional values of x , *not the fractional values of* $1.2.3 \dots x$, but the fractional values of the function whose whole values are contained in $1.2.3 \dots x$.

Theory of
Pro-
babilities.

(56.) The method adopted by Laplace is that of expressing such functions as $[s]$ by means of definite integrals, in which the variable of integration is not s , but an independent quantity whose limits are given. Nothing better tends to illustrate the calculus of variations than this method, which repeats its process and result with different meanings and hypotheses. We shall give one case at length as an exposition of the method. Required a continuous function of x , which shall, whenever x is a whole number, be equivalent to $1.2.3 \dots s$. If we call this y , we have $y_{s+1} = (s+1)y_s$, which we assume to be a universal property of the values of x . If there be any definite integral of the form $\int_a^b \phi(x, s) dx$, which is $\psi(s, a, b)$, then by the well-known properties of constants in integration, we have $\int_a^b \phi(x, s+1) dx = \psi(s+1, a, b)$. If we assume $y_s = \int_a^b x^s \cdot \phi \cdot dx$, where ϕ is to be a function of x only, we find

$$\begin{aligned} y_{s+1} - (s+1)y_s &= \int_a^b (x^{s+1} - (s+1)x^s) \phi dx \\ &= \int_a^b x^{s+1} \phi dx - x^{s+1} \phi + \int_a^b x^{s+1} \frac{d\phi}{dx} dx, \text{ from } x=a \text{ to } x=b \\ &= a^{s+1} \phi_a - b^{s+1} \phi_b + \int_a^b \left(\phi + \frac{d\phi}{dx} \right) x^{s+1} dx. \end{aligned}$$

Now if we propose for ϕ such a function that the last term shall be integrable, we may make the whole expression $=0$, and shall have done what is required, subject to this condition, that one of the two, a or b , must be a function of the other and of s . Our object is to have a and b fixed and independent of s , which can be done by assuming $\phi + \frac{d\phi}{dx} = 0$, or $\phi = C \varepsilon^{-x}$, which leaves $C a^{s+1} \varepsilon^{-a} - C b^{s+1} \varepsilon^{-b}$; and this can be made equal to 0 consistently with y_s being finite,* by $a^{s+1} = 0$, and $\varepsilon^{-b} = 0$, or $a = 0$, $b = \infty$. This gives the following:

$$\begin{aligned} \text{If} \quad y_{s+1} &= (s+1)y_s \quad y_s = C \int_0^\infty x^s \varepsilon^{-x} dx \quad y_0 = C \int_0^\infty \varepsilon^{-x} dx = C, \\ \text{or} \quad y_s &= y_0 \int_0^\infty x^s \varepsilon^{-x} dx. \end{aligned}$$

But when s is a whole number, it is obvious that $y_s = y_0 \cdot 2 \cdot 3 \cdot 4 \dots s$, whence $\int_0^\infty \varepsilon^{-x} x^s dx = [s]$, when s is a whole number, and is a continuous function, such that $y_{s+1} = (s+1)y_s$ in all cases where s is positive.

In the preceding process, we naturally ask why the form $\int x^s \phi dx$ was preferred to any other? Observe, that the question, generalized, is as follows: given

$$\psi s + \psi_1 s \cdot y_s + \psi_2 s \cdot y'_s + \dots \quad (A),$$

required an expression of this function as an integral, in such a manner that the integral may have certain definite limits independent of the value of s . Now in the calculus of variations, which we here mention not to recall the object of that science, but only its process, we have the solution of the following problem. Given y and x , of which the former is an indeterminate function of the latter, and f being a given functional form required the separation of

$$\int f\left(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots\right) dx \dots (B)$$

into a function of the form

$$P_0 + P_1 \frac{d\omega}{dx} + P_2 \frac{d^2\omega}{dx^2} + \dots + \int \chi\left(x, y, \frac{dy}{dx}, \dots\right) \times \omega dx \quad (C),$$

where ω is an indeterminate function of x , and $P_0, P_1, \dots$ and χ are determined. This being done, the equation $\chi = 0$ makes y such a function of x as leaves the disappearance of the preceding between given limits depending only on satisfying the equation $\Pi_2 - \Pi_1 = 0$, where Π_2 and Π_1 are the values of the terms of (C) which precede $\int$, for the superior and inferior limits. In the calculus of variations those limits are given, or at least subject to one or more relations. In the present subject they are part of the *quæsitæ* of the problem. And thus the preceding expression is made to disappear, independently of the general form of ω , though values of ω at the limits may be specified.

To reduce the expression (A) to the form (B), we must observe that s is not to be a function of any continuous variable mentioned, but if y_s , &c. be expressed by definite integral functions of x , must be an arbitrary constant. And the most obvious method is to take such a function of x and s that all the terms in (A) may be easily represented by differential coefficients of the functions, combined with functions of x ; so that s may not appear except in the functions just mentioned. Let $\gamma(x, s)$ be one of those functions, giving readily ψs in terms of γ , its differential coefficients with respect to x , and x itself. If, then, we assume

$$y_s = \int \gamma \times \phi \times dx, \quad y'_s = \int \gamma \times \phi' \times dx, \text{ \&c.,}$$

where ϕ, ϕ' , &c. are functions of x only, it is plain that we may, under the preceding supposition with respect to $\psi s, \psi_1 s$, &c., express (A), which now becomes

$$\psi s + \int \psi_1 s \cdot \gamma \cdot \phi \cdot dx + \int \psi_2 s \cdot \gamma \cdot \phi' \cdot dx + \text{\&c.,}$$

in the form $\int f\left(x, \phi, \phi' \dots \gamma, \frac{d\gamma}{dx}, \dots\right) dx$, and from thence, choosing γ itself for the function ω , we may reduce

* If we attain the condition by making $a=b$, we have $y_s = 0$, which is one solution, seeing that $0 = (s+1) \times 0$.

Theory of
Pro-
babilities.

the preceding to the form (C), determine the forms of ϕ , ϕ' , &c. under which the integral will vanish independently of its limits, and the limits of integration under which the preceding part will satisfy given conditions. In general, χ , in the expression (C), will be a function of γ , ϕ , ϕ' , &c., and their differential coefficients, which will lead to the preliminary solution of a differential equation.

Theory of
Pro-
babilities.

(57.) The only cases of ψs , $\psi_1 s$, &c. which it will be necessary to consider are rational and integral functions of s . Now a rational and integral function of s may be expressed in either of the following forms, consistently with easy reference to usual theorems:

$$\begin{aligned}\psi s &= A_0 + A_1 s + A_2 s(s-k) + A_3 s(s-k)(s-2k) + \&c. \\ \psi s &= B_0 + B_1 s + B_2 s^2 + B_3 s^3 + \&c. \\ A_n &= \frac{1}{1.2.3\dots n} \times \left(\frac{\Delta^n \psi s}{k^n} \right) \quad B_n = \frac{1}{1.2.3\dots n} \times \left(\frac{d^n \psi s}{ds^n} \right),\end{aligned}$$

where $\Delta \psi s = \psi(s+k) - \psi s$, and the brackets indicate the value for $s=0$. In the case of common differences, where $k=1$, the assumption of $\gamma(x, s) = x^s$ gives

$$\begin{aligned}s(s-1)(s-2)\dots(s-n+1) &= \frac{d^n \gamma}{dx^n} \times \frac{x^n}{\gamma} \\ \psi s &= \frac{1}{\gamma} \left(A_0 \gamma + A_1 x \frac{d\gamma}{dx} + A_2 x^2 \frac{d^2 \gamma}{dx^2} + \dots \right).\end{aligned}$$

In the second form given to ψs the assumption of $\gamma(x, s) = \varepsilon^{-sx}$ (where ε^{sx} would do equally well, but it is desirable to have a function which vanishes when x is infinite and *positive*, for convenience merely) gives

$$\begin{aligned}s^n &= (-1)^n \frac{1}{\gamma} \frac{d^n \gamma}{dx^n} \\ \psi s &= \frac{1}{\gamma} \left(B_0 \gamma - B_1 \frac{d\gamma}{dx} + B_2 \frac{d^2 \gamma}{dx^2} - \&c. \right)\end{aligned}$$

If in the first case we assume $y_s = \int x^s \cdot \phi \cdot dx$, we have, by the convertibility of independent differentiations and integrations,

$$\begin{aligned}\frac{dy_s}{ds} &= \int x^s \cdot \phi \cdot \log x \, dx \dots \frac{d^n y_s}{ds^n} = \int x^s \cdot \phi \cdot (\log x)^n \, dx \\ \Delta y_s &= y_{s+1} - y_s = \int x^{s+1} \phi \cdot dx \dots \Delta^n y_s = \int x^{s+n} \phi \cdot dx,\end{aligned}$$

the limits being those employed in y_s .

When we assume $y_s = \int \varepsilon^{-sx} \phi \, dx$, we have

$$\begin{aligned}\frac{dy_s}{ds} &= - \int \varepsilon^{-sx} x \phi \, dx \dots \frac{d^n y_s}{ds^n} = (-1)^n \int \varepsilon^{-sx} x^n \phi \, dx \\ \Delta y_s &= \int \varepsilon^{-sx} (\varepsilon^{-x} - 1) \phi \, dx \dots \Delta^n y_s = \int \varepsilon^{-sx} (\varepsilon^{-x} - 1)^n \phi \, dx.\end{aligned}$$

(58.) We shall apply this method to the expression of s^{-i} and $\Delta^n \cdot s^{-i}$. The reader must remember that the reason of this apparently complicated method of expressing simple formulæ is, that there is a method to be presently explained of expressing the definite integrals so obtained, in series which are very convergent when the numbers n and i are large, which is usually the case in the theory of probabilities.

$$y_s = s^{-i} \text{ gives } s \frac{dy_s}{ds} + i y_s = 0. \text{ Let } y_s = \int \varepsilon^{-sx} \phi \cdot dx, \varepsilon^{-sx} = \gamma$$

$$\int \left\{ \frac{1}{\gamma} \frac{d\gamma}{dx} x \gamma \phi \, dx + i \gamma \phi \, dx \right\} = 0$$

$$\int \left(\frac{d\gamma}{dx} x \phi + i \gamma \phi \right) dx = \gamma \cdot x \phi + \int \left(i \phi - \frac{d(x\phi)}{dx} \right) \gamma \, dx = 0.$$

Let

$$i \phi - \frac{d(x\phi)}{dx} = 0, \text{ or } \phi = A x^{i-1}, \text{ which gives } \gamma \cdot x \phi = \varepsilon^{-sx} \cdot A x^i.$$

The limits of the integration being $x=0$, $x=\infty$, the term $\gamma x \phi$ vanishes at both limits, and the equation is satisfied; we have then

$$s^{-i} = A \int_0^\infty \varepsilon^{-sx} x^{i-1} \, dx, \text{ and } 1 = A \int_0^\infty \varepsilon^{-sx} x^{i-1} \, dx,$$

the latter being what the former becomes when $s=1$; and we have, therefore,

$$s^{-i} = \frac{\int_0^\infty \varepsilon^{-sx} x^{i-1} \, dx}{\int_0^\infty \varepsilon^{-sx} x^{i-1} \, dx}, \quad \Delta^n \cdot s^{-i} = \frac{\int_0^\infty \varepsilon^{-sx} (\varepsilon^{-x} - 1)^n x^{i-1} \, dx}{\int_0^\infty \varepsilon^{-sx} x^{i-1} \, dx},$$

the denominator being constant with respect to s .

(59.) Having thus shown that such functions as the preceding can be reduced to definite integrals, we shall for the present leave this part of the subject, and proceed to inquire in what way these integrals may be expanded into convergent series. Since the object is to expand functions containing high powers or many factors, we have first to ask *what functions of high powers are necessarily small*, in order that we may endeavour to obtain series arranged in powers of such small quantities.

Theory of
Pro-
babilities.

The terms great and small have, relatively to each other, a determinate conventional meaning, though, absolutely speaking, they have no fixed meaning. If s be called great, $\frac{1}{s}$ is to be called small, and *vice versa*.

Theory of
Pro-
babilities.

This is definition. But further, the terms great and small are never applied except in cases where the terms "as great as we please" or "as small as we please" may supply their places, by carrying the initial supposition, out of which greatness and smallness arose, "as far as we please." For instance, "when x is small, $\sin x$ and $x - \frac{1}{6}x^3$ are nearly equal," is a common theorem. But this theorem implies more; it is really equivalent to the

following: "By taking x sufficiently small, we may make $\sin x$ and $x - \frac{1}{6}x^3$ as nearly equal as we please; or $\frac{\sin x}{x - \frac{1}{6}x^3}$ as near to 1 as we please."

And in all that follows the student is carefully to watch that he is never led into admitting* that p is small when q is nearly $=r$, except upon proof that p may be made as small as he pleases, by making q as near to r as may be requisite. With this accompaniment, we may freely use the indeterminate terms small and great, without the implied circumlocutions.

Let n be great, then u^n is neither small nor great, necessarily; being the first when u is less than unity, and the second when u is greater than unity. But its logarithm, $n \log u$, and the differential coefficient $\frac{n}{u} \frac{du}{dx}$, are great, if u be independent of n . (Remember, this means that $\frac{1}{u} \frac{du}{dx}$ being a fixed quantity, n times as much may be made as great as we please by making n sufficiently great.) If the preceding be then called $\frac{1}{v}$, we have a small quantity in v ; and if $y = u^s u^{s'} \dots \times \phi$, where $s, s', \&c.$, any or all, are great, we have a small quantity in

$$\frac{y}{\frac{dy}{dx}}, \text{ or } \frac{1}{\frac{s}{u} \frac{du}{dx} + \frac{s'}{u'} \frac{du'}{dx} + \dots + \frac{1}{\phi} \frac{d\phi}{dx}} = v.$$

(60.) PROBLEM. To expand $\int y dx$ in terms of v . We have then

$$\begin{aligned} \int y dx &= \int v dy = vy - \int y \frac{dv}{dx} dx = vy - \int v \frac{dv}{dx} dy \\ &= vy - vy \frac{dv}{dx} + \int y \frac{d}{dx} \frac{v dv}{dx} dx = vy - vy \frac{dv}{dx} + vy \frac{d}{dx} \frac{v dv}{dx} - \int y \frac{d}{dx} v \frac{d}{dx} v \frac{dv}{dx} dx; \end{aligned}$$

and, proceeding in this way, we find

$$\int y dx = vy \left(1 - \frac{dv}{dx} + \frac{d}{dx} v \frac{dv}{dx} - \frac{d}{dx} v \frac{d}{dx} v \frac{dv}{dx} + \&c. \right),$$

which is to be taken in the usual manner between the limits, when they are given. It will be observed that the differential coefficients of $\frac{dv}{dx}$ are also small quantities; and, in general, we know that if a function be necessarily small, on account of a great constant which appears in the denominator, the differential coefficients will also be small. So that if we say that v is of the first order of smallness, $v \frac{dv}{dx}$ will be of the second; $v \frac{d}{dx} v \frac{dv}{dx}$ of the third, and so on: that is, the preceding series will be convergent. But we must except the case in which one of the limits is near that value of x which makes y a maximum or a minimum, for then $\frac{dy}{dx}$ may be small, and v not small. For instance, if $y = x^n \epsilon^{-x}$, we have $v = \frac{x}{n-x}$, which is, generally, small when n is great, except only when x is nearly equal to n . For practical use, x must be small as compared with n ; and the series is altogether inapplicable when $n = x$, in which case $\frac{dy}{dx} = 0$. As it is this latter case which is most useful, a special method has been applied by Laplace.

(61.) Previous to entering on this method it may be useful to show in a more common way the principle on which a series becomes convergent when the *exponents* of a previous equation are great numbers. Suppose we have

$$(A - Bx^{n+1} + Cx^{n+2} - \dots)',$$

in which all powers of x are wanting up to the n th inclusive. If we assume the preceding $= A' \epsilon^{-x^{n+1}}$, and take the s th root of both sides, expanding the exponential, we have

* It is quite impossible a beginner can clearly understand what follows unless he attend to this point.

Theory of
Pro-
babilities.

$$A - Bx^{n+1} + Cx^{n+2} - \dots = A \left(1 - \frac{t^{n+1}}{s} + \frac{t^{2n+2}}{2s^2} - \&c. \right),$$

Theory of
Pro-
babilities.

of which the common reversion of series shows that x can be expanded in the form $Pt + Qt^2 + \dots$, and that P , Q , &c. decrease rapidly when s is great compared with n , or when $\frac{1}{s^{n+1}}$ is considerable. And to determine P we have

$$BP^{n+1} = \frac{A}{s} \quad P = \sqrt[n+1]{\frac{A}{Bs}} \quad x = Pt \text{ nearly.}$$

(62.) Let $x=a$ make $\frac{1}{y} \frac{dy}{dx} = 0$; whence it follows that $(x-a)^\mu$ (μ being positive) is a factor of $\frac{1}{y} \frac{dy}{dx}$, and $(x-a)^{\mu+1}$ is a factor of the integral of the preceding, or of $\log y + C$, provided C be so taken that the preceding shall vanish when $x=a$. Both factors are the highest of their kind. Let Y be the value of y corresponding to $x=a$, then $(x-a)^{\mu+1}$ is a factor of $\log y - \log Y$. If, then, the latter* be called $-t^{\mu+1}$, we find that $x-a$ is a factor of t . Let

$$t = \frac{x-a}{v}, \text{ or } x = a + vt \dots (1),$$

where v does not become infinite when $x=a$; for if it did, we should know that $(x-a)^\nu$ is a factor of $\frac{1}{v}$, and $(x-a)^\nu$ is not then the highest power of $x-a$ which is a factor of t . The preceding also gives

$$v = \overline{x-a} (\log Y - \log y)^{-\frac{1}{\mu+1}}, \text{ a function of } x;$$

so that from (1), by Lagrange's theorem, we have

$$x = a + (v)t + \left(\frac{d \cdot v^2}{dx} \right) \frac{t^2}{2} + \left(\frac{d^2 \cdot v^3}{dx^2} \right) \frac{t^3}{2 \cdot 3} + \&c.,$$

where the brackets are placed to denote that x is made $=a$ after the differentiations. The bracketed terms are then functions of a only. If we differentiate the last equation, and multiply by

$$y = Y \varepsilon^{-t^{\mu+1}}, \text{ making } G_n \text{ stand for } \int t^n \varepsilon^{-t^{\mu+1}} dt,$$

we have

$$\int y dx = Y \left((v) G_0 + \left(\frac{d \cdot v^2}{dx} \right) G_1 + \left(\frac{d^2 \cdot v^3}{dx^2} \right) \frac{G_2}{2} + \&c. \right).$$

The question is, therefore, reduced to the determination of G_0 , G_1 , &c., or in general of G_n ; belonging to a succeeding part of the subject, the actual investigation of definite integrals. But, as these integrals are of a degree of importance in this science almost corresponding to that of successive powers in algebra, we shall at once proceed to show how they may be found. We must observe, however, that we shall have little, if any thing, to do with any case except where $\mu=1$; that is, with the form

$$G_n = \int t^n \varepsilon^{-t^2} dt.$$

Integrate the preceding one step by parts, which gives

$$G_n = -\frac{1}{2} t^{n-1} \varepsilon^{-t^2} + \frac{n-1}{2} G_{n-2}.$$

Write $n-2$ for n , which gives G_{n-2} in terms of G_{n-4} , and so on; the ultimate forms being G_1 when n is odd, G_0 when n is even; of which G_1 is algebraically integrable, for

$$G_1 = \int \varepsilon^{-t^2} t dt = -\frac{1}{2} \varepsilon^{-t^2};$$

and G_0 or $\int \varepsilon^{-t^2} dt$ remains to be found. We have then

$$\begin{aligned} G_{2n+1} &= -\frac{\varepsilon^{-t^2}}{2} \left\{ t^{2n} + n t^{2n-2} + n \cdot \overline{n-1} t^{2n-4} + \dots + [n, 2] t^2 + [n, 1] \right\} \\ G_{2n} &= -\frac{\varepsilon^{-t^2}}{2} \left\{ t^{2n-1} + \frac{2n-1}{2} t^{2n-3} + \frac{2n-1}{2} \frac{2n-3}{2} t^{2n-5} + \dots + \frac{2n-1}{2} \frac{2n-3}{2} \dots \frac{3}{2} t \right\} \\ &\quad + \frac{2n-1}{2} \cdot \frac{2n-3}{2} \dots \frac{3}{2} \frac{1}{2} \int \varepsilon^{-t^2} dt. \end{aligned}$$

To determine G_0 from $t=0$ to $t=\infty$ let

$$U = \int_0^\infty \int_0^\infty \varepsilon^{-(1+x^2)} dx ds = \int_0^\infty \frac{dx}{1+x^2} = \frac{\pi}{2};$$

the integrations being made, first for s , then for x , and the given limits used. Now perform the integrations in the inverse order denoted by

$$U = \int_0^\infty (\varepsilon^{-s} ds \int_0^\infty \varepsilon^{-sx^2} dx).$$

But

$$\int_0^\infty \varepsilon^{-sx^2} dx = \frac{1}{\sqrt{s}} \int_0^\infty \varepsilon^{-(\sqrt{s} \cdot x)^2} d(\sqrt{s} \cdot x) = \frac{1}{\sqrt{s}} \int_0^\infty \varepsilon^{-t^2} dt$$

* The negative sign is an anticipation. It will hereafter be found that Y is generally greater than y , so that an explicitly negative equivalent form of $\log y - \log Y$ will be convenient.

Theory of Probabilities. for a definite integral does not depend on the letter used for the variable, but on its limits. We have then

Theory of Probabilities.

$$U = \int_0^\infty G_0 \varepsilon^{-t} s^{-\frac{1}{2}} ds = G_0 \int_0^\infty \varepsilon^{-v^2} 2dv, \text{ if } v^2 = s \\ = G_0 \times 2G_0 = 2G_0^2; \text{ whence } 2G_0^2 = \frac{\pi}{2} \quad G_0 = \frac{\sqrt{\pi}}{2}$$

or

$$\int_0^\infty \varepsilon^{-t^2} dt = \frac{1}{2} \sqrt{\pi} \quad \int_{-\infty}^{+\infty} \varepsilon^{-t^2} dt = \sqrt{\pi};$$

the last being a consequence of a well-known property of integrals of the form $\int \phi(t^2) dt$. It now remains to show how to approximate to the value of this same integral from $t=0$ to $t=a$, where a is any number or fraction. By simply expanding ε^{-t^2} in powers of t^2 , and integrating, the first of the following series is found: the second is found by integrating by parts, as in

$$G_0 = \varepsilon^{-t^2} \cdot t + \frac{2}{3} \int \varepsilon^{-t^2} d \cdot t^3, \text{ \&c. ;}$$

and the third by the same method, applied as follows:

$$G_0 = -\frac{\varepsilon^{-t^2}}{2t} - \frac{1}{2} \int \frac{\varepsilon^{-t^2}}{t^2} dt, \text{ \&c} \\ \int_0^a \varepsilon^{-t^2} dt = a - \frac{a^3}{3} + \frac{a^5}{2 \cdot 5} - \frac{a^7}{2 \cdot 3 \cdot 7} + \frac{a^9}{2 \cdot 3 \cdot 4 \cdot 9} - \text{\&c.} \\ \int_0^a \varepsilon^{-t^2} dt = a \varepsilon^{-a^2} \left(1 + \frac{2a^2}{3} + \frac{4a^4}{3 \cdot 5} + \frac{8a^6}{3 \cdot 5 \cdot 7} + \text{\&c.} \right) \\ \int_a^\infty \varepsilon^{-t^2} dt = \frac{\varepsilon^{-a^2}}{2a} \left(1 - \frac{1}{2a^2} + \frac{1 \cdot 3}{4a^4} - \frac{1 \cdot 3 \cdot 5}{8a^6} + \text{\&c.} \right)$$

The first two are always convergent, but the convergence is distant and slow if a be greater than 2. The third is never convergent, and is not from $t=0$ to $t=a$, but from $t=a$ to $t=\infty$. But we know that

$$\int_0^\infty \phi dt = \int_0^a \phi dt + \int_a^\infty \phi dt,$$

whence

$$\int_0^a \varepsilon^{-t^2} dt = \frac{1}{2} \sqrt{\pi} - \int_a^\infty \varepsilon^{-t^2} dt.$$

(63.) The third series may be converted into a continued fraction, which shall become more convergent the more divergent the series; as follows. Let

$$u = \frac{1}{x} - \frac{q}{x^3} + \frac{3q^2}{x^5} - \frac{3 \cdot 5q^3}{x^7} + \text{\&c.}$$

which gives

$$q \frac{du}{dx} = ux - 1.$$

Let u be developed in powers of $1-x$, as follows:

$$u = y_0 + y_1(1-x) + y_2(1-x)^2 + \text{\&c.}$$

By comparing $q \frac{du}{dx}$, and $ux - 1$, or $u - (1-x)u - 1$, we find

$$y_0 - 1 = -qy_1, \quad y_1 - y_0 = -2qy_2, \quad y_2 - y_1 = -3qy_3,$$

and, generally,

$$y_{r+1} - y_r = -(r+2)qy_{r+2}.$$

Hence

$$y_0 = \frac{1}{1 + q \frac{y_1}{y_0}} \quad \frac{y_1}{y_0} = \frac{1}{1 + 2q \frac{y_2}{y_1}} \text{ \&c., or } y_0 = \frac{1}{1 + q \frac{1}{1 + 2q \frac{1}{1 + 3q \frac{1}{1 + \text{\&c.}}}}}$$

But y_0 is the value of u when $1-x=0$, or when $x=1$; the series for which from the first series is

$$1 - q + 3q^2 - 3 \cdot 5q^3 + \text{\&c.}$$

Let $q = \frac{1}{2a^2}$, and we have from the third series for G_0

$$\int_a^\infty \varepsilon^{-t^2} dt = \frac{\varepsilon^{-a^2}}{2a} \cdot \frac{1}{1 + q \frac{1}{1 + 2q \frac{1}{1 + 3q \frac{1}{1 + \text{\&c.}}}}}$$

The successive approximations to the continued fraction being

$$1, \quad \frac{1}{1+q}, \quad \frac{1+2q}{1+3q}, \quad \frac{1+5q}{1+6q+3q^2}, \quad \frac{1+9q+8q^2}{1+10q+15q^2}, \quad \text{\&c. ;}$$

Theory of
Pro-
babilities.

which, if q be less than $\frac{1}{4}$, or a greater than $\sqrt{2}$, converge rapidly. For values, see the Table at the end of this Work.

Theory of
Pro-
babilities.

(64.) If we proceed in the same manner as in (62.), with

$$\int_0^\infty \int_0^\infty \varepsilon^{-s(1+x^n)} ds dx, \text{ or } \int_0^\infty \frac{dx}{1+x^n}, \text{ or } \frac{\pi}{n \sin \frac{\pi}{n}},$$

we find the following result, by a method analogous to that just cited:

$$n \int_0^\infty \varepsilon^{-t^n} dt \times \int_0^\infty t^{n-2} \varepsilon^{-t^n} dt = \frac{\pi}{n \sin \frac{\pi}{n}}$$

For n write $\frac{n}{r-1}$, and for t write t^{r-1} , which gives

$$n^2 \int_0^\infty t^{r-2} \varepsilon^{-t^n} \times \int_0^\infty t^{n-r} \varepsilon^{-t^n} dt = \frac{\pi}{\sin \left(\frac{r-1}{n} \cdot \pi \right)}.$$

Adopting the notation of Legendre, namely $\Gamma(a+1)$ for $\int_0^\infty \varepsilon^{-x} x^a dx$, and making $n=1$ in the preceding, and $r-1=v$, this becomes

$$\Gamma(v) \times \Gamma(1-v) = \frac{\pi}{\sin \pi v}.$$

(65.) Having found G_0 we may see from (62.) that

$$\int_0^\infty t^{2n+1} \varepsilon^{-t^2} dt = \frac{1}{2} n(n-1)(n-2) \dots 3 \cdot 2 \cdot 1 = G_{2n+1}$$

$$\int_0^\infty t^{2n} \varepsilon^{-t^2} dt = \frac{2n-1}{2} \cdot \frac{2n-3}{2} \dots \frac{3}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} \sqrt{\pi} = G_{2n}$$

$$\int_{-\infty}^{+\infty} t^{2n+1} \varepsilon^{-t^2} dt = 0 \quad \int_{-\infty}^{+\infty} t^{2n} \varepsilon^{-t^2} dt = \frac{2n-1}{2} \dots \frac{3}{2} \cdot \frac{1}{2} \sqrt{\pi};$$

whence, in (62.), $\int y dx$, taken between such values of x as make $t=-\infty$ and $t=+\infty$, (the most common case,) we have

$$\int y dx = Y \sqrt{\pi} \left((v) + \frac{1}{2} \cdot \frac{1}{1 \cdot 2} \left(\frac{d^3 \cdot v^3}{dx^2} \right) + \frac{1 \cdot 3}{2^2} \cdot \frac{1}{1 \cdot 2 \cdot 3 \cdot 4} \left(\frac{d^4 \cdot v^4}{dx^4} \right) + \&c. \right)$$

$$v = \frac{(x-a)}{\sqrt{\log Y - \log y}} \quad t = \sqrt{\log Y - \log y}.$$

On looking at $y = Y \varepsilon^{-t^2}$, we see that $t=-\infty$ gives $y=0$; $t=0$ gives $y=Y$ a maximum; $t=+\infty$ gives $y=0$; so that, in fact, the preceding is the expression for the integral throughout the interval, at the beginning and end of which $y=0$, and Y is the intermediate maximum or minimum value of y . And $t=0$ gives $x=a$. If $x=a+\theta$, and if $Y, Y'=0, Y'', \&c.$ be the values of $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \&c.$ corresponding to $x=a$, we have

$y = Y + \frac{1}{2} Y'' \theta^2 + \&c.$ by Taylor's theorem. Consequently,

$$\log Y - \log y = -\log \left(1 + \frac{1}{2} \frac{Y''}{Y} \theta^2 + \dots \right) = -\frac{1}{2} \frac{Y''}{Y} \theta^2 + \dots$$

$$\sqrt{\log Y - \log y} = \theta \sqrt{-\frac{1}{2} \frac{Y''}{Y} + \dots} \quad v = \sqrt{\frac{2Y}{-Y''} + A_1 \theta + A_2 \theta^2 + \dots}$$

Consequently (v) , made by making $x=a$ or $\theta=0$, is $\sqrt{\frac{2Y}{-Y''}}$, giving (very nearly)

$$\int y dx = \pm \sqrt{2\pi} \frac{Y^{\frac{3}{2}}}{\sqrt{-Y''}} \dots \dots (A).$$

If Y be positive, then it is an algebraical maximum, and Y'' is negative. If Y be negative, it is an algebraical minimum, and Y'' is positive. In either case the preceding expression is possible. In the first case the positive sign must be taken; in the second case the negative.

(66.) The preceding process may be thus more synthetically performed. Let Y be the maximum or minimum value of y corresponding to $x=a$, and let $y = Y \varepsilon^{-t^2}$, there being two values of x for which $y=0$, one on each side of Y , and if t be determined by the preceding equation, answering to $t=-\infty$ and $t=+\infty$. Assume $x=a+\theta$, giving

Theory of
Pro-
babilities.Theory of
Pro-
babilities.

$$y = Y + Y'' \frac{\theta^2}{2} + Y''' \frac{\theta^3}{2 \cdot 3} + \dots$$

or

$$-t^2 = \log \left(1 + \frac{Y''}{Y} \frac{\theta^2}{2} + \frac{Y'''}{Y} \frac{\theta^3}{2 \cdot 3} + \dots \right) = -A_2 \theta^2 - A_3 \theta^3 - \&c.$$

from which, by reversion, let

$$\theta = B_1 t + B_2 t^2 + \dots \quad d\theta = dx = B_1 dt + 2B_2 t dt + \dots$$

$$\int y dx = Y (B_1 G_0 + 2B_2 G_1 + 3B_3 G_2 + \&c.);$$

the integrals being taken from $t = -\infty$ to $t = +\infty$. This gives

$$\int y dx = Y \sqrt{\pi} \left(B_1 + \frac{3}{2} B_2 + \frac{15}{4} B_3 + \&c. \right)$$

It is easily ascertained that $B_1 Y \sqrt{\pi}$ is the term (A), as given in the last article.

(67.) If in the equation

$$1 + \frac{Y''}{Y} \frac{\theta^2}{2} + \frac{Y'''}{Y} \frac{\theta^3}{2 \cdot 3} + \dots = e^{-t^2}$$

we substitute $B_1 t + B_2 t^2 + B_3 t^3 + \dots$ for θ , and expand the first and second sides, we find by equation of coefficients

$$B_1 = \sqrt{-\frac{2Y}{Y''}} \quad B_2 = \frac{1}{3} \frac{Y''' Y}{Y''^2} \quad B_3 = \frac{9Y'''^2 Y + 5Y''' Y''^2 - 3Y^{iv} Y'' Y^2}{18Y''^4} \sqrt{-\frac{Y}{2Y''}}$$

(68.)* The preceding principles are applied to the determination of $\int y dx dx'$ in the following manner. Let this integral be required between limits which severally give $y=0$, and let $x=a$, $x'=a'$ be the values which give the maximum intermediate value of y . Let Y be this maximum, and assume

$$y = Y e^{-t^2 - t'^2},$$

 t and t' being new variables. Let $x=a+\theta$, $x'=a'+\theta'$, which gives, remembering that Y' and Y'' , or $\frac{dy}{dx}$ and $\frac{dy}{dx'}$, (when $x=a$, $x'=a'$), are severally $=0$,

$$Y + A \theta^2 + 2B \theta \theta' + C \theta'^2 = Y e^{-t^2 - t'^2}$$

where A , B , and C are functions of θ and θ' ; the whole of Taylor's series, from terms of the second degree upwards, being capable of such an arrangement in an infinite number of different ways. For instance, the term $P \theta^6 \theta'^3$ might be written either as $P \theta^4 \theta'^3 \cdot \theta^2$, or $P \theta^3 \theta'^4 \cdot \theta \theta'$, or $P \theta^6 \theta'^3 \cdot \theta'^3$, and might be brought into either of the three last terms. Divide by Y , take the logarithms of both sides, and change the signs, which gives an equation of the form

$$M \theta^2 + 2N \theta \theta' + P \theta'^2 = t^2 + t'^2,$$

which may be satisfied by an infinite number of relations between t , θ , θ' , and t' , θ , θ' . Resolve the first side into the sum of two squares, which equate to t^2 and t'^2 , giving

$$t = M^{-\frac{1}{2}} (M\theta + N\theta') \quad t' = M^{-\frac{1}{2}} (MP - N^2)^{\frac{1}{2}} \theta' \dots (1),$$

and by differentiation

$$dt = L d\theta + I d\theta' \quad dt' = L' d\theta + I' d\theta'.$$

These latter equations follow necessarily from the preceding, independently of all suppositions as to the method of differentiating, it not even being requisite that this should be the same in both. It only remains to see what peculiar forms of them are required by the method of differentiating implied in $\int y dx dx'$, which is given, and its equal $\int T dt dt'$, which is to be found. In the first $dx = d\theta$, $dx' = d\theta'$. Let $\int y d\theta d\theta' = V$, and suppose θ' expressed in terms of θ and t from the first of (1), which requires that we should determine $d\theta'$ from

$$d\theta' = \frac{dt}{I} - \frac{L}{I} d\theta,$$

or from this as it will be when its value has been substituted for θ' in L and I .But $d\theta'$ in $\int y d\theta \cdot d\theta'$ was obtained on the supposition that $d\theta = 0$, whence $d\theta' = \frac{dt}{I}$ or $\int y d\theta d\theta' = \int \frac{y d\theta dt}{I}$, which contains θ and t without θ' or t' . Now substitute for θ its value in terms of t and t' derived from both equations in (1), remembering that dt' is to be considered as obtained simultaneously with $dt=0$, that is, from

$$0 = L d\theta + I d\theta', \quad dt' = L' d\theta + I' d\theta',$$

or

$$d\theta = \frac{I dt'}{L'I - LI'}, \text{ giving } \int y d\theta d\theta' = Y \int \frac{e^{-t^2 - t'^2} dt dt'}{L'I - LI'}.$$

The denominator of the integral is a function of t and t' derived from the inversion of (1); and in the same manner as in (65.), where it is shown that the first term of the series gives a sufficient approximation, we may use instead of M , N , and P , their first terms, which are constants, namely,

$$M = -\frac{Y''}{2Y} \quad 2N = -\frac{Y'}{Y} \quad P = -\frac{Y}{2Y'}$$

* Any reader who is not very well versed in analysis is recommended to omit this Article.

Theory of
Pro-
babilities.

$Y'', Y',$ and $Y_{//}$ being the values of $\frac{d^2y}{dx^2}$, $\frac{d^2y}{dx dx'}$, and $\frac{d^2y}{dx'^2}$, when $x=a$, $y=a'$. Hence it is easily found that

Theory of
Pro-
babilities.

$$L = \sqrt{M} \quad I = \frac{N}{\sqrt{M}} \quad L' = 0 \quad I' = \sqrt{\frac{PM - N^2}{M}}$$

$$\int y dx dx' = \pm \frac{Y}{\sqrt{PM - N^2}} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \varepsilon^{-t^2 - t'^2} dt dt' = \pm \frac{2\pi Y^2}{\sqrt{Y'' Y_{//} - (Y')^2}}$$

on the sign of which remarks similar to those in (65.) apply.*

(69.) The following results will be easily obtained :

$$\int \varepsilon^{-t^2} t dt = -\frac{1}{2} \varepsilon^{-t^2}$$

$$\int \varepsilon^{-t^2} t^2 dt = -\frac{1}{2} t \varepsilon^{-t^2} + \frac{1}{2} \int \varepsilon^{-t^2} dt$$

$$\int \varepsilon^{-t^2} t^3 dt = -\frac{1}{2} \varepsilon^{-t^2} (t^2 + 1)$$

&c. &c. &c.

Hence, when the series in (62.) is to be taken from $t=T$ to $t=T'$, we have (if we make

$$\left(\frac{d^{n-1} \cdot v^n}{dx^{n-1}} \right) = Y_n,$$

and let $a-\theta$ and $a+\theta'$ be the values of x corresponding to $t=T$ and $t=T'$ the following equation :

$$\int_{a-\theta}^{a+\theta'} y dx = Y \left(Y_1 + \frac{1}{2} \frac{Y_3}{1 \cdot 2} + \frac{1 \cdot 3}{2^2} \frac{Y_5}{1 \cdot 2 \cdot 3 \cdot 4} + \&c. \right) \int_T^{T'} \varepsilon^{-t^2} dt$$

$$+ \frac{Y}{2} \varepsilon^{-T^2} \left(Y_2 + T \frac{Y_3}{2} + (T^2 + 1) \frac{Y_4}{2 \cdot 3} + \&c. \right)$$

$$- \frac{Y}{2} \varepsilon^{-T'^2} \left(Y_2 + T' \frac{Y_3}{2} + (T'^2 + 1) \frac{Y_4}{2 \cdot 3} + \&c. \right)$$

The first line of the preceding is sufficiently convergent when y contains large exponents. the second and third are convergent if T and T' be not too great. To examine this further, observe that if $\frac{1}{\alpha}$ be a large quantity of the same order as the exponents in question, in which case α will be a small quantity, then v , containing $\log y$ under a square root in the denominator, will be of the order $\sqrt{\alpha}$, so that $Y_1, Y_2, Y_3, \&c.$ will be of the order $\sqrt{\alpha}, \alpha, \sqrt{\alpha^3}, \&c.$ Consequently T and T' should not be of an order much superior to $\frac{1}{\sqrt{\alpha}}$, or else the series will converge very slowly.

(70.) We shall now proceed to some examples of the methods here laid down. We have shown (56.) that

$$1 \cdot 2 \cdot 3 \dots s = \int_0^{\infty} \varepsilon^{-x} x^s dx \quad y = \varepsilon^{-x} x^s.$$

Now $\varepsilon^{-x} x^s$ is a maximum when $x=s$, and is 0 when $x=0$, or when $x=\infty$. For as x^s increases by increase of x , ε^{-x} increases in continually greater ratio, as appears sufficiently evident, if we consider the effect of increasing an exponent, compared with that of increasing the root of a power. The student should apply the common methods of the differential calculus. Let then $x=s+\theta$, $Y=s^s \varepsilon^{-s}$, and assume

$$\varepsilon^{-(s+\theta)^2} = \varepsilon^{-s^2} \varepsilon^{-s\theta} \varepsilon^{-\theta^2} \dots (1).$$

To follow our method we must differentiate $\varepsilon^{-x} x^s$ continually, and make $x=s$ in the several results, in order to obtain $Y', Y'', \&c.$ The shortest way to do this is to differentiate $y \varepsilon^x = x^s$, which gives, calling $y^{(n)}$ the n th differential coefficient of y ,

$$y' + y = s x^{s-1} \varepsilon^{-x}, \quad y'' + 2y' + y = s(s-1) x^{s-2} \varepsilon^{-x}, \quad \&c.$$

$$y^{(n)} + n y^{(n-1)} + \dots + n y' + y = [s, s-n+1] x^{s-n} \varepsilon^{-x},$$

from which we get $Y' = 0, \quad Y'' = -\frac{1}{s} Y, \quad Y''' = \frac{2}{s^2} Y, \quad Y^{(4)} = \left(\frac{3}{s^2} - \frac{6}{s^3} \right) Y, \quad \&c.,$

or from (67.)

$$B_1 = \sqrt{2s}, \quad B_2 = \frac{2}{3}, \quad B_3 = \frac{1}{9} \cdot \frac{1}{\sqrt{2s}}, \quad \&c.$$

$$\int_0^{\infty} x^s \varepsilon^{-x} dx = s^s \varepsilon^{-s} \sqrt{\pi} \left\{ \sqrt{2s} + \frac{3}{2} \cdot \frac{1}{9} \cdot \frac{1}{\sqrt{2s}} + \&c. \right\}$$

* We have only indicated the principal steps of this result, as its complete developement would require more space than its importance entitles us to allow it. The reason of the difficulty is the incomplete manner in which the comparison of differentiations under different circumstances is treated in all the elementary works on the Differential Calculus.

Theory of
Pro-
babilities.Theory of
Pro-
babilities.

$$1 \cdot 2 \cdot 3 \dots s = s^{s+\frac{1}{2}} \varepsilon^{-s} \sqrt{2\pi} \left\{ 1 + \frac{1}{12s} + \&c. \right\}.$$

When s is a large number this series converges rapidly. If s be so great that the second and following terms may be neglected, we have what we should have obtained from the approximate value in (65.), namely,

$$1 \cdot 2 \cdot 3 \dots s = s^{s+\frac{1}{2}} \varepsilon^{-s} \sqrt{2\pi} = \sqrt{2\pi s} \left(\frac{s}{\varepsilon} \right)^s \dots (P).$$

But this result may be, in this particular case, more simply obtained from (1) by dividing both sides by $\varepsilon^{-s} s^s$, and taking the logarithm of both sides, which gives

$$-\theta + s \log \left(1 + \frac{\theta}{s} \right) = -t^2,$$

or

$$t^2 = \frac{\theta^2}{2s} - \frac{\theta^3}{3s^2} + \frac{\theta^4}{4s^3} - \&c.,$$

by the reversion of which we obtain

$$\theta = \sqrt{2s} \cdot t + \frac{2}{3} t^3 + \frac{1}{9\sqrt{2s}} t^5 + \&c.;$$

from hence we may find $d\theta$ or dx , and hence $\int y dx$, as before.

(71.) This series is also a simple result of the well-known theorem which expresses Σy , or $y_0 + y_1 + \dots + y_{s-1}$ in terms of $\int y ds$ and differential coefficients of y , namely, if $t(\varepsilon^t - 1)^{-1}$ be expanded as follows,

$$\frac{t}{\varepsilon^t - 1} = 1 - \frac{t}{2} + \beta_1 \frac{t^2}{2} - \beta_2 \frac{t^3}{2 \cdot 3 \cdot 4} + \&c.,$$

which developement must necessarily* be the true form: then it may be shown that

$$\Sigma y = \int y ds - \frac{1}{2} y + \frac{\beta_1}{2} \frac{dy}{ds} - \frac{\beta_2}{2 \cdot 3 \cdot 4} \frac{d^2 y}{ds^2} + \&c.$$

In this theorem it is most important to remember that an alteration in the meaning of Σ , as to the terms with which it shall begin, is equivalent to nothing but an alteration of the arbitrary constant in the integral $\int y ds$.

This theorem may be shown thus: if Σy can be expanded in a series of the form

$$\Sigma y = A_0 \int y ds + A_1 y + A_2 \frac{dy}{ds} + \dots (A),$$

where $A_0, A_1, A_2, \&c.$ are the same for all functions, we may determine them by substituting any function of y , of which we know the developement. Let ε^{ks} be the function chosen; then

$$\Sigma \varepsilon^{ks} = 1 + \varepsilon^k + \varepsilon^{2k} + \dots + \varepsilon^{(s-1)k}, \text{ or } \frac{\varepsilon^{ks} - 1}{\varepsilon^k - 1},$$

which gives

$$\frac{\varepsilon^{ks} - 1}{\varepsilon^k - 1} = A_0 \left(\frac{\varepsilon^{ks}}{k} + \text{constant} \right) + A_1 \varepsilon^{ks} + A_2 k \varepsilon^{ks} + \&c.$$

As this constant of integration is independent of s , let s be infinite and negative, or $\varepsilon^{ks} = 0$, which gives

$$-\frac{1}{\varepsilon^k - 1} = A_0 \times \text{constant}.$$

Subtract this from the former, and divide by ε^{ks} , which gives

$$\frac{1}{\varepsilon^k - 1} = \frac{A_0}{k} + A_1 + A_2 k + A_3 k^2 + \dots;$$

which, compared with the preceding developement, gives

$$A_0 = 1 \quad A_1 = -\frac{1}{2} \quad A_2 = \frac{\beta_1}{2} \quad A_3 = 0, \&c.$$

It only remains then to show that Σy can be expressed by such a series as that assumed. We know that, in all cases,

$$\Delta y = \frac{dy}{ds} + \frac{1}{2} \frac{d^2 y}{ds^2} + \frac{1}{2 \cdot 3} \frac{d^3 y}{ds^3} + \&c.$$

For y , write $\int y ds$, and then sum both sides, or perform the operation Σ on both, which gives

$$\int y ds = \Sigma y + \frac{1}{2} \Sigma \frac{dy}{ds} + \frac{1}{2 \cdot 3} \Sigma \frac{d^2 y}{ds^2} + \&c.$$

$$\Sigma y = \int y ds - \frac{1}{2} \Sigma \frac{dy}{ds} - \&c.$$

* This function gives $\phi t - \phi(-t) = -t$; and if $a_0 + a_1 t + \dots$ be made to satisfy this condition, we find that $a_1 = -\frac{1}{2}$, and that $a_2, a_3, \&c.$ disappear.

Theory of
Pro-
babilities.Substitute $\frac{dy_s}{ds}$ for y_s , successively, which gives

$$\begin{aligned}\sum \frac{dy_s}{ds} &= y_s - \frac{1}{2} \sum \frac{d^2 y_s}{ds^2} - \&c. \\ \sum \frac{d^2 y_s}{ds^2} &= \frac{dy_s}{ds} - \frac{1}{2} \sum \frac{d^3 y_s}{ds^3} - \&c.,\end{aligned}$$

Theory of
Pro-
babilities.

by substituting each of which in the preceding the first is reduced to the form in (A).

The numbers $\beta_1, \beta_2, \&c.$ are called the numbers of Bernoulli, and would be a very important element of our subject, if it were not that the very great convergence of the series renders many terms unnecessary.

The most simple method of obtaining them is from the expression given by Sir J. Herschel, (*Examples Calc Diff.* p. 81), namely,

$$\beta_{2x-1} = (-1)^x \left\{ \frac{\Delta \cdot 0^{2x}}{2} - \frac{\Delta^2 \cdot 0^{2x}}{3} + \frac{\Delta^3 \cdot 0^{2x}}{4} - \dots \pm \frac{\Delta^{2x} \cdot 0^{2x}}{2x+1} \right\};$$

then

$$\beta_1 = \frac{1}{6} \quad \beta_2 = \frac{1}{30} \quad \beta_3 = \frac{1}{42}.$$

To calculate the last, observe that $x=3$, $(-1)^x = -1$, and the successive differences of the first term of the series $0^6, 1^6, 2^6, \dots$ are 1, 62, 540, 1560, 1800, 720, whence

$$\beta_3 = - \left\{ \frac{1}{2} - \frac{62}{3} + \frac{540}{4} - \frac{1560}{5} + \frac{1800}{6} - \frac{720}{7} \right\} = \frac{1}{42}.$$

If we apply the theorem to the case of $y_s = \log p_s$, we find

$$\begin{aligned}\log p_0 + \log p_1 + \dots + \log p_s &= \sum \log p_s + \log p_s \\ &= \int \log p_s ds + \frac{1}{2} \log p_s + \frac{\beta_1}{2} \frac{d \cdot \log p_s}{ds} - \&c. \\ &= - \int \frac{s}{p_s} \frac{dp_s}{ds} ds + \left(s + \frac{1}{2} \right) \log p_s + \frac{\beta_1}{2} \frac{d \cdot \log p_s}{ds} - \&c.,\end{aligned}$$

and the inverse logarithmic process gives

$$p_0 p_1 \dots p_s = \varepsilon^{-V} p_s^{s+\frac{1}{2}} \left\{ 1 + \frac{1}{12 p_s} \frac{d \cdot p_s}{ds} + \&c. \right\};$$

putting V for $\int \frac{s}{p_s} \frac{dp_s}{ds} ds$, and $\frac{1}{6}$ for β_1 . The theorem in (70.) (making $p_s = s$) may be confirmed by this in every point except the factor $\sqrt{2\pi}$, which comes from the arbitrary constant to be added to V , namely, $\log \sqrt{2\pi}$ in this case. In fact, the difficulty of determining this constant renders the preceding theorem practically useless, though, as we have seen, the necessity does not occur in the method of Laplace.

(72.) To form an idea of the degree of approximation which the equation (P) makes to exactness, write $s+1$ for s , and divide the result by (P), which gives

$$s+1 = (s+1) \left(1 + \frac{1}{s} \right)^{s+\frac{1}{2}} \varepsilon^{-1}, \text{ or } \varepsilon = \left(1 + \frac{1}{s} \right)^s \sqrt{1 + \frac{1}{s}}.$$

This equation evidently becomes true when s is infinite, from a well-known property of $(1+s^{-1})^s$, namely, that its limit is ε when s increases without limit. Taking the common logarithms of both sides of the last, we have

$$.4342945 = \left(s + \frac{1}{2} \right) (c \cdot \log s + 1 - c \cdot \log s).$$

We shall not be very far from the truth, considering how little approximation we ought then to expect, if we make $s=1$, which gives .45154 for the second side of the equation. If $s=9$, we get .4348 on the second side. The approximation is therefore very rapid: the result being a little too great.

(73.) The method of (70.) applied to $y_s = 1.3.5 \dots 2s-1$ will give

$$1.3.5 \dots 2s-1 = \frac{2^{s+1}}{\sqrt{\pi}} \int_0^\infty x^{2s} \varepsilon^{-x^2} dx = 2^{s+\frac{1}{2}} \left(\frac{s}{\varepsilon} \right)^s \text{ nearly.}$$

This we leave to the reader, and also the deduction of Wallis's theorem, namely, that

$$\frac{\pi}{4} = \frac{2}{3} \cdot \frac{4}{3} \cdot \frac{4}{5} \cdot \frac{6}{5} \cdot \frac{6}{7} \cdot \frac{8}{7} \dots \text{ad. inf.}$$

(74.) We shall now consider the case alluded to in (22.), where a large number of events being to happen, each of which must happen in one of two ways, with known probabilities in favour of either, it is required to know the probability in favour of a given degree of departure from the most likely collection of events. Suppose, for example, the chance of drawing a white ball to be $\frac{2}{3}$, and that of a black ball $\frac{1}{3}$, we are going to solve generally a question of this kind:—in 3000 drawings which are relatively more likely to give 2000 white balls

Pro-
babilities.

than any other individual number, what is the probability that the number of white balls will lie between 2000 + 100 and 2000 - 100? Let these two possible events be denoted by P and Q, and let p and q be their probabilities; whence $p + q = 1$. Let the number of drawings be $x + x'$ where $x : x' :: p : q$, so that the most likely case is that P shall happen x times and Q shall happen x' times. Let $x + x' = n$, so that $np = x$, $nq = x'$; and let P_{-l} be the probability that P shall happen exactly $x - l$ times out of n , and Q, $x' + l$ times. Then P_{-l} is that term of the developement of $(p + q)^{x+x'}$, which contains $p^{x-l} q^{x'+l}$.

Theory of
Pro-
babilities.

$$P_{-l} = \frac{1.2.3 \dots n}{1.2.3 \dots (x-l) \times 1.2.3 \dots (x'+l)} p^{x-l} q^{x'+l}$$

$$= \frac{n^{n+\frac{1}{2}} \varepsilon^{-n} \sqrt{2\pi}}{(x-l)^{x-l+\frac{1}{2}} \varepsilon^{-x+l} \sqrt{2\pi} \cdot (x'+l)^{x'+l+\frac{1}{2}} \varepsilon^{-x'-l} \sqrt{2\pi}} \times \left(\frac{x}{n} \right)^{x-l} \left(\frac{x'}{n} \right)^{x'+l} \left. \vphantom{\frac{n^{n+\frac{1}{2}} \varepsilon^{-n} \sqrt{2\pi}}{(x-l)^{x-l+\frac{1}{2}} \varepsilon^{-x+l} \sqrt{2\pi} \cdot (x'+l)^{x'+l+\frac{1}{2}} \varepsilon^{-x'-l} \sqrt{2\pi}}} \right\} \text{very nearly,}$$

$$= \sqrt{\frac{n}{2\pi}} (x-l)^{-x+l-\frac{1}{2}} (x'+l)^{-x'-l-\frac{1}{2}} x^{x-l} x'^{x'+l};$$

which is incorrect by terms of the order $\frac{1}{x}, \frac{1}{x'}$, at most. Now the logarithm of the second factor is

$$\left(-x + l - \frac{1}{2} \right) \log(x-l), \text{ or } \left(-x + l - \frac{1}{2} \right) \left(\log x - \frac{l}{x} - \frac{l^2}{2x^2} \right) \text{ nearly;}$$

or $\left(-x + l - \frac{1}{2} \right) \log x + l - \frac{l^2}{2x} + \frac{l}{2x},$ rejecting $\frac{1}{x^2}$, &c.;

or the factor is $x^{-x+l-\frac{1}{2}} \varepsilon^{\frac{l^2}{2x}} \left(1 + \frac{l}{2x} \dots \right).$

To make the third factor, change x into x' , and l into $-l$, which gives, rejecting $\frac{1}{xx'}$, the following for the approximate value of P_{-l} ,

$$\sqrt{\frac{n}{2\pi}} x^{-x+l-\frac{1}{2}+x-l} x'^{-x'-l-\frac{1}{2}+x'+l} \varepsilon^{\frac{l^2}{2x} - \frac{l^2}{2x'}},$$

or

$$\sqrt{\frac{n}{2\pi xx'}} \varepsilon^{-\frac{nl^2}{2xx'}}.$$

And the same for P_l , the probability of P happening $x + l$ times exactly, since the preceding is a function of l^2 . Hence the probability of the number of white balls being either $x - l, x - l + 1, \dots, x + l - 1, x + l$, is the following

$$P_{-l} + P_{-l+1} + \dots + P_{l-1} + P_l = 2 \sqrt{\frac{n}{2\pi xx'}} \Sigma \varepsilon^{-\frac{nl^2}{2xx'}} - P_0 + 2P_l,$$

where Σ includes every value of l from 0 to $l-1$. Without the subtraction, the term answering to $l=0$ would have been repeated twice on the second side.

If l be under $\sqrt{x}$ and $\sqrt{x'}$, or thereabouts, the exponent of ε will be of the order $\frac{1}{x}$ at most, and its differential coefficients decrease rapidly; we have, therefore,

$$\Sigma \varepsilon^{-\frac{nl^2}{2xx'}} = \int \varepsilon^{-\frac{nl^2}{2xx'}} dl - \frac{1}{2} \varepsilon^{-\frac{nl^2}{2xx'}} + \text{constant};$$

and, since Σ and $\int$ are to begin together at $l=0$, we have constant $= \frac{1}{2}$. We have, therefore,

$$2 \sqrt{\frac{n}{2\pi xx'}} \Sigma \varepsilon^{-\frac{nl^2}{2xx'}} - P_0 + 2P_l = 2 \sqrt{\frac{n}{2\pi xx'}} \int_0^l \varepsilon^{-\frac{nl^2}{2xx'}} dl + \sqrt{\frac{n}{2\pi xx'}} \varepsilon^{-\frac{nl^2}{2xx'}}.$$

But the first side represents the probability of the number of Ps being between $x-l$ and $x+l$. Suppose

$$l \sqrt{\frac{n}{2xx'}} = t \dots (1),$$

then the second side of the preceding becomes

$$\frac{2}{\sqrt{\pi}} \int_0^t \varepsilon^{-t^2} dt + \frac{t}{\sqrt{\pi}} \varepsilon^{-t^2} \dots$$

$$= 1 - \frac{2}{\sqrt{\pi}} \int_t^\infty \varepsilon^{-t^2} dt + \frac{t}{\sqrt{\pi}} \varepsilon^{-t^2} \dots (A).$$

We shall give an instance (being that whose result is stated, Laplace, p. 281) as follows. Supposing 18 boys are born to 17 girls, in which case out of 14,000 births the most likely individual case is, that 7200 should be boys, and 6800 girls, what is the probability that the number of boys shall fall between 7200 ± 163 ?

Theory of
Pro-
babilities.

$$\begin{aligned}x &= 7200 \\ x' &= 6800 \\ n &= 14000 \\ l &= 163\end{aligned}$$

Theory of
Pro-
babilities.

$$\begin{aligned}\log x &= 3.85733 \\ \log x' &= 3.83251 \\ \log 2 &= 0.30103 \\ \hline &7.99087 \\ \log n &4.14613 \\ \hline &2) 4.15526 \\ \log t \div l &= 2.07763 \\ \log l &2.21219 \\ \hline \log t &0.28982 \quad t=1.949 \\ &2 \\ \hline &0.57964 \\ \log .43429 &1.63778 \\ \hline &.21742 \\ \\ .43459 t^2 &= 1.6498 \\ - .43459 t^2 &= 2.35020 \quad = \log . \varepsilon^{-t^2} \\ \log t \div l &= 2.07763 \\ \hline \text{Comp. log } \frac{\sqrt{\pi}}{2} &0.05246 \\ \text{Comp. log } 2 &1.69897 \\ \hline .00015 &4.17926\end{aligned}$$

It is, therefore, .99433 to .00567, or 175 to 1, that the number of male births shall be within the limits specified. Such a problem as the preceding will explain how it is that offices dealing in calculable contingencies are not precarious speculations. The truth is that, properly managed, and with a real knowledge of their contingencies, they are, so soon as they command steady supplies of business, by many times more safe than any other species of mercantile adventure whatsoever. If we suppose, for example, an office which engages to give a certain sum to families on the birth of each son, on receiving a suitable consideration. Putting other risks aside, and attending to this one only, it appears that, if they can command a continual supply of business to such an amount as will give them the chances of 14,000 children, and if they are correct in calculating the relative births in the whole country at 18 boys to 17 girls, they will, by calculating their premiums on the supposition that 163 out of 7200 cases will happen contrary to expectation, make it extremely unlikely that they should sustain any loss by what would be called the accidental fluctuations of the proportion.

(75.) Let l be a certain fraction of n , namely, en , or 100 e per cent. of n . We have then

$$t = en \sqrt{\frac{n}{2xx'}} = e \sqrt{n} \times \sqrt{\frac{n^2}{2xx'}} = \frac{e \sqrt{n}}{\sqrt{2pq}};$$

and the probability of an excess or defect not exceeding 100 e per cent. in n drawings is

$$\Pi_e = 1 - \frac{2}{\sqrt{\pi}} \int_t^\infty \varepsilon^{-t^2} dt + \frac{\varepsilon^{-t^2}}{\sqrt{2\pi pqn}}.$$

When the chances are even, we have $t = e \sqrt{2n}$,

$$\Pi_e = 1 - \frac{2}{\sqrt{\pi}} \int_t^\infty \varepsilon^{-t^2} dt + \frac{\varepsilon^{-t^2}}{\sqrt{\frac{1}{2}\pi n}}.$$

In both these formulæ t varies as $e \sqrt{n}$, and the third term is very small when compared with the second; whence in drawing rough conclusions we shall consider the two first terms only. The greater t is, the smaller is the second term, and when t is as great as 3 the tables show that the second term is very small. But $t=3$ gives $e=3 \div \sqrt{2n}$; and if we were to suppose $n=5000$, we should have $e=.03$, or 3 per cent. It is, therefore, next to impossible, as the phrase is, that out of 5000 even risks of the same kind the total loss or gain should amount to 3 per cent. of the whole sum staked. But if $x=200$, then $e=.15$, or 15 per cent. The probability of this loss or gain from fluctuation is then excessively small. If we make $e=.10$, and $n=128$, we have $t=1.6$, and $\Pi_e=.024$ nearly, or about 40 to 1 against accidental fluctuation causing loss or gain of 10 per cent.

It must be borne in mind that the absolute safety of life contingency offices depends upon two circumstances. 1. The correctness of their tables, or rather their being on the right side of correctness. 2. The quantity of the variations from the assumed standard of events. Now considering that such offices always set out with tables

Theory of
Pro-
babilities.

confessedly favourable to themselves, (as they ought to do,) and add at least 10 per cent. for fluctuation and commercial profit, it is clear from the preceding that any idea of their being insecure from the course of events, independently of improper management, should be out of the question altogether. The preceding instances are fair representatives of the mass of their transactions, as follows. In an insurance-office, for instance, some die before they have paid enough, while some pay their policies perhaps twice over before they die. Supposing the tables to be correct, and the premiums calculated accordingly, it is, as far as can be known, an even chance whether any given individual shall fall among their good or their bad bargains. And, though the preceding is not precisely the problem of determining the question of probable excess or defect to a given amount, it is one of the same kind, and will serve to show perfectly well the order of probability which exists for the gain or loss in question.

(76.) It is evident from the preceding that, t remaining the same, e varies inversely as the root of n (in all cases). Consequently, if for a given number of events it be prudent to count upon a fluctuation of 10 per cent. from the most probable case, it is not *twice* as many events that will justify calculating upon 5 per cent. of fluctuation, but *four* times as many.

(77.) In what precedes we have the probability that the number of times P will happen out of n throws will lie between l times more and l times less than the number which is individually most probable. We shall now consider the inverse question, namely, supposing the event to have happened x times out of $x+x'$, or n , what

presumption* is there that the probability of P happening lies between $\frac{x}{n}+k$ and $\frac{x}{n}-k$? Let p be the probability in question, then, making

$$[x'] \times [x] \div [x+x'] = X,$$

it is evident that the probability of the observed event is $X p^x (1-p)^{x'}$, whence the presumption of the probability

lying between p and $p+dp$ is $\left(\frac{x}{n} = \omega\right)$,

$$\frac{X p^x (1-p)^{x'} dp}{X \int_0^1 p^x (1-p)^{x'} dp}, \text{ and } \frac{\int_{\omega-k}^{\omega+k} p^x (1-p)^{x'} dp}{\int_0^1 p^x (1-p)^{x'} dp}$$

is the presumption required. Let us then suppose $y = p^x (1-p)^{x'}$, considered as a function of p , and by (66.) this presumption is very nearly

$$\frac{B_1 \int \epsilon^{-t^2} dt + 2B_2 \int t \epsilon^{-t^2} dt}{B_1 \int_{-\infty}^{+\infty} \epsilon^{-t^2} dt + 2B_2 \int_{-\infty}^{+\infty} t \epsilon^{-t^2} dt};$$

which, since the second term of the denominator vanishes, and the first is $\sqrt{\pi} B_1$, is the same as

$$\frac{1}{\sqrt{\pi}} \int \epsilon^{-t^2} dt + \frac{2B_2}{B_1 \sqrt{\pi}} \int t \epsilon^{-t^2} dt \dots (1);$$

the indefinite integrals in both cases being taken between those values of t , which correspond to $p = \omega - k$ and $p = \omega + k$. We must now find B_1 and B_2 . The maximum value of y is ω , consequently $p = \omega$ and $t = 0$ are simultaneous; and by differentiation it will be ascertained that $y, y', y'',$ and y''' in the case of $p = \omega$, or $Y, Y', Y'',$ and Y''' , may be thus obtained. Differentiate the equation

$$\log y = x \log p + x' \log (1-p)$$

three times successively; giving $\left(\omega = \frac{x}{n}, 1-\omega = \frac{x'}{n}\right)$,

$$\frac{y'}{y} = \frac{x}{p} - \frac{x'}{1-p}, \quad \frac{Y'}{Y} = 0$$

$$\frac{y y'' - y'^2}{y^2} = -\frac{x}{p^2} - \frac{x'}{(1-p)^2}, \quad \frac{Y''}{Y} = -\frac{n^2}{x x'}$$

$$\frac{y^2 (y y''' - y' y'') - (y y'' - y'^2) 2y y'}{y^4} = \frac{2x}{p^3} - \frac{2x'}{(1-p)^3}, \quad \frac{Y'''}{Y} = -\frac{2n^2 (x-x')}{x^2 x'^2}$$

$$B_1 = \sqrt{-\frac{2Y}{Y''}} = \sqrt{\frac{2x x'}{n^2}}, \quad B_2 = \frac{1}{3} \frac{Y''' Y}{Y'^2} = -\frac{2}{3} \frac{x-x'}{n^2}, \quad Y = \left(\frac{x}{n}\right)^x \left(\frac{x'}{n}\right)^{x'}$$

Hence if $p = \omega + \theta$, we have $\theta = B_1 t + B_2 t^2 + \dots$; and for small values of θ we have $\theta = B_1 t$. Whence, supposing k to be small, we have to integrate from

$$t = -k \sqrt{\frac{n^2}{2x x'}} \text{ to } t = +k \sqrt{\frac{n^2}{2x x'}}$$

* To avoid using such a phrase as the probability of a probability, writers on this subject usually employ a synonyme. Thus Laplace talks of the probability of the *facility* of P happening, and English writers speak of the *possibility* of P having its probability. We have used the phrase in the text as being more English; we cannot reconcile our ears to *degrees of possibility*.

Theory of
Pro-
babilities.

Theory of
Pro-
babilities.

which makes the second integral in (1) vanish, and reduces the first to

$$\frac{1}{\sqrt{\pi}} \int_{-t}^{+t} \varepsilon^{-t^2} dt, \text{ or } \frac{2}{\sqrt{\pi}} \int_0^k \sqrt{\frac{n^3}{2xx'}} \varepsilon^{-t^2} dt.$$

Theory of
Pro-
babilities.

If we suppose the variation of probability k to be such as would lead us to expect $x+l$ throws where there are now x , out of n , then would $x+l=n(\omega+k)$, or $l=nk$, so that the superior limit of integration would be

$l\sqrt{\frac{n}{2xx'}}$, the same as before, and the expression obtained is the same as the first term of that which precedes (A) in (74.)

The preceding expression may be thus stated, to accord with our tables: if P happen x times out of $x+x'$, then the presumption that the probability of P happening in any one instance lies between $\frac{x}{n}+k$ and $\frac{x}{n}-k$ (k being small) is nearly

$$1 - \frac{2}{\sqrt{\pi}} \int_t^\infty \varepsilon^{-t^2} dt, \quad t = k\sqrt{\frac{n^3}{2xx'}}.$$

The preceding process fails from the commencement when $x'=0$, and y becomes p^x , both by giving an expression of a different form, and also by presuming a probability $1+k$ greater than 1. But in this case the presumption that p lies between 1 and $1-k$ may be found from the expression

$$\int_{1-k}^1 p^x dp \div \int_0^1 p^x dp, \text{ or } 1 - (1-k)^{x+1}.$$

If 100 balls out of 101 be white, and the remaining one black, the presumption that the probability of drawing a white ball lies between $\frac{100}{101} \pm .01$ is .68. If there be 100 balls drawn, all white, the last formula makes the presumption that the same lies between 1 and $1-.01$ to be .63.

(78.) We have introduced the preceding articles in order that the student who does not wish to go very far into the subject may stop here with some view of the manner in which the higher branches of analysis become the abbreviators of operation which we have described them to be in (1.) We now resume the preliminary mathematics of the subject, preparatory to more extensive applications.

The following results of integration are readily obtained. The limits of integration are written after them, the inferior limit below.

$$\begin{aligned} \int_a^b \varepsilon^{-rt^2} dt &= \frac{1}{\sqrt{r}} \int_{a\sqrt{r}}^{b\sqrt{r}} \varepsilon^{-v^2} dv & \int_{-\infty}^{+\infty} t^{2n} \varepsilon^{-rt^2} dt &= \frac{2n-1}{2r} \cdot \frac{2n-3}{2r} \cdots \frac{3}{2r} \frac{1}{2r} \frac{\sqrt{\pi}}{\sqrt{r}} \\ \int_a^b \varepsilon^{-rt^2+st+c} dt &= \frac{1}{\sqrt{r}} \varepsilon^{\frac{s^2}{4r}+c} \int_{v=\sqrt{r}\left(a-\frac{s}{2r}\right)}^{v=\sqrt{r}\left(b-\frac{s}{2r}\right)} \varepsilon^{-v^2} dv & \int_{-\infty}^{+\infty} t^{2n} \varepsilon^{-rt^2+st} dt &= \varepsilon^{\frac{s^2}{4r}} \int_{-\infty}^{+\infty} \left(t+\frac{s}{2r}\right)^{2n} \varepsilon^{-rt^2} dt. \end{aligned}$$

(79.) Previously to proceeding further, the character of definite integrals will require some discussion, particularly as to those in which impossible quantities enter. By $\int y dx$, taken from $x=a$ to $x=b$, is generally understood $\phi b - \phi a$ where ϕx is that function of x which, differentiated, gives y . But, 1. This definition is not the point of view under which integration is considered in its applications either to geometry or physics. 2. It is not a proper assumption to speak of $\int y dx$ as a function obeying the laws of algebra, in those instances in which we have not the most remote idea what such function may be, and when, in all probability, it is a transcendental of a class which algebra has no present means of expressing, or of knowing whether it has not peculiar properties. May it not, for example, have some properties which set ordinary theorems of algebra at defiance? (See the Calculus of Functions, art. 72.) We require a definition peculiar to a definite integral, and we find it in the view which actually exists of such a function in geometry and mechanics. The definite integral of $\phi x dx$, taken from $x=a$ to $x=b$, means the following: divide the interval $b-a$ into n equal parts, each $=\theta$; then form

$$\theta \{ \phi a + \phi(a+\theta) + \phi(a+2\theta) + \dots + \phi(a+n\theta, \text{ or } b) \}.$$

The limit of this, made by diminishing θ or increasing n without limit, is the definite integral in question. We do not here inquire into the general form of the function for all values of a , but we require only the expression for n terms of a given series, or, where that cannot be found, its limit as n increases without limit, subject to $n\theta=b-a$. But it must be observed that this definition only applies in cases where ϕx does not become infinite in the interval between $x=a$ and $x=b$. In this case the general term $\theta\phi(a+m\theta)$ does not always necessarily diminish without limit, and other considerations are necessary to be introduced, which have been considered by M. Poisson.* But such cases will not need to be considered in the integrals which this subject introduces. It may be shown† that this definition of a definite integral agrees with the common one in all cases in which an inverse

* Journal de l'Ecole Polytechnique, cahier 18, vol. xi.

† Also Differential Calculus, (Library of Useful Knowledge.)

Theory of
Pro-
babilities.

differential coefficient can be found, to which Taylor's theorem may be applied. What we are now concerned with is the passage from possible to impossible functions, and most particularly in the case of exponential functions, which we may now consider, in common algebra, as freed from anomalous results.

Theory of
Pro-
babilities.

(80.) But we must first remark (as we suppose others have done, though we have not met with it) that we have no right to assume a definite integral to be properly expressed in analysis by the symbol ∞ , because the numerical result is infinite: such assumption being precisely the same as that $1+2+4+8+\dots$ is infinite, because its arithmetical summation is so. We know the latter to be expressed by -1 , and the reasons are explained in works on algebra. We cannot doubt that the successive acquisition of 1, 2, 4, 8, $\dots$ counters would lead to the acquisition of any number in time; or that the area of the curve whose ordinate is ε^x might be made to contain as many square feet as we please by taking the abscissa x sufficiently great. What we say is, that those who would contend for $\int_0^\infty \varepsilon^x dx = \infty$ must be required to show cause why $1+2+4+\dots$ should not be regarded as also infinite; while those who abide by the result $1+(1+p)+(1+p)^2+\dots = -\frac{1}{p}$ may be made to know that $\int_0^\infty \varepsilon^{px} dx = -\frac{1}{p}$ on the same grounds. For it is obvious that

$$\theta (\varepsilon^{p\theta} + \varepsilon^{2p\theta} + \varepsilon^{3p\theta} + \dots \text{ad inf}) = \frac{\theta \varepsilon^{p\theta}}{1 - \varepsilon^{p\theta}} = -\frac{1}{p}, \text{ when } \theta = 0,$$

by the common rules of the differential calculus. When p is negative, this result is also arithmetically true, in like manner as $1 + \frac{1}{2} + \frac{1}{4} + \dots = 2$. And if it be necessary to ask of every algebraical *infinite*, whether it is numerically infinite, or has become negative by passing through infinity, the same question must be put as to a result of the integral calculus. And if any should contend for the infinity of a definite integral, by referring its value to that obtained from the ordinary definition, we should ask them how, in any particular problem, they prove the continuity of the arbitrary constant which forms a part of the general expression, in the precise case where the variable is infinite? (See Calculus of Functions, art. 181, &c.)

(81.) We shall now show the consistency of the results derived from passing from possible to impossible quantities. Let us take the cases of $\int_0^\infty \cos x dx$ and $\int_0^\infty \sin x dx$, as derived from the definition. By taking

$$\theta (\cos \theta + \cos 2\theta + \cos 3\theta + \dots), \text{ or } -\frac{\theta}{2}$$

$$\theta (\sin \theta + \sin 2\theta + \sin 3\theta + \dots), \text{ or } \frac{1}{2} \frac{\theta \sin \theta}{1 - \cos \theta},$$

which severally approach to 0 and 1 when θ is diminished without limit, we have

$$\int_0^\infty \cos x \cdot dx = 0, \quad \int_0^\infty \sin x \cdot dx = 1.$$

By using the following equation,

$$\int_0^\infty = \int_0^{\frac{\pi}{2}} + \int_{\frac{\pi}{2}}^\pi + \int_\pi^{\frac{3\pi}{2}} + \&c.,$$

we obtain for the first integral $1-1-1+1+1-\&c.$, or $1-2\left(\frac{1}{2}\right)=0$. For the second, we have $+1+1-1-1+\&c.$, or $2\left(\frac{1}{2}\right)$, or 1. These results will be better understood, by taking the arithmetical cases of which they are limits, that is, $\int_0^\infty \varepsilon^{-px} \cos x dx$ and $\int_0^\infty \varepsilon^{-px} \sin x dx$, p being positive. By integrating these, whether by common process or by finding

$$\sum_{m=0}^{\infty} \varepsilon^{-mp\theta} \cos m\theta \cdot \theta, \text{ and } \sum_{m=0}^{\infty} \varepsilon^{-mp\theta} \sin m\theta \cdot \theta,$$

it will be found that, for every positive value of p , however small, the first ($\theta=0$) is arithmetically $\frac{p}{1+p^2}$, and the second $\frac{1}{1+p^2}$; the limits of which (p diminishing without limit) are 0 and 1. And the same results have been deduced by M. Poisson and others, in various other ways. We shall now apply these integrals to the case of

$$\int_0^\infty \varepsilon^{\pm x \sqrt{-1}} = \int_0^\infty \cos x dx \pm \sqrt{-1} \int_0^\infty \sin x dx,$$

the second side of which, treated in the manner just shown, gives $\pm \sqrt{-1}$, or $\mp \frac{1}{\sqrt{-1}}$, a result agreeing with that

obtained from the right-hand side in the usual manner, by means of the equation $\int_0^\infty \varepsilon^{px} dx = -\frac{1}{p}$, before established in all cases.

The integral $y = \int_0^\infty \varepsilon^{-a^2 x^2} \cos rx dx$ may be thus obtained without impossible quantities. Differentiate with respect to r , which gives

Theory of
Pro-
babilities.

or

$$\frac{dy}{dr} = -\int_0^\infty \varepsilon^{-a^2 x^2} \sin rx \cdot x dx = -\frac{r}{2a^2} \int_0^\infty \varepsilon^{-a^2 x^2} \cos rx dx$$

$$\frac{dy}{dr} + \frac{r}{2a^2} y = 0, \quad y = B \varepsilon^{-\frac{r^2}{4a^2}},$$

Theory of
Pro-
babilities.

where B must be the value of y when $r=0$; that is, $\int_0^\infty \varepsilon^{-a^2 x^2} dx$, or (78.)

$$\int_0^\infty \varepsilon^{-a^2 x^2} \cos rx dx = \frac{\sqrt{\pi}}{2a} \varepsilon^{-\frac{r^2}{4a^2}}.$$

Now substitute the exponential value for $\cos rx$, find $\int_0^\infty \varepsilon^{-a^2 x^2 \pm rx \sqrt{-1}} dx$, as in (78.), and the same result will be obtained.

(82.) We shall now proceed to find approximate values for coefficients of given powers of a , in the expression

$$(a^{-n} + a^{-n+1} + \dots + a^{-1} + 1 + a + \dots + a^{n-1} + a^n)^s \dots (1),$$

where n and s are high numbers. If we call P_l the coefficient of a^l in this formula, we see firstly that a^{-l} has the same coefficient, so that the formula may be written

$$P_0 + P_1(a + a^{-1}) + P_2(a^2 + a^{-2}) + \dots (2);$$

or, if we make $a + a^{-1} = 2 \cos \varpi$, the formula becomes

$$P_0 + 2P_1 \cos \varpi + 2P_2 \cos 2\varpi + \dots (3).$$

But, if we take the following equation, (v and w being whole numbers,) multiply both sides by $d\varpi$, and integrate from $\varpi=0$ to $\varpi=\pi$,

$$\cos v \varpi \cos w \varpi = \frac{1}{2} \cos (v-w) \varpi + \frac{1}{2} \cos (v+w) \varpi,$$

we find that, according as v differs from or is equal to w ,

$$\int_0^\pi \cos v \varpi \cos w \varpi d\varpi = 0, \text{ or } \frac{1}{2} \pi.$$

This holds also when $w=0$. Hence, if we multiply (3) by $\cos l\varpi$, and integrate, we find every term of the result evanescent, except only that which arises from $2P_l \cos l\varpi$, which becomes πP_l . But when $l=0$, owing to the first term not being multiplied by 2, the result is $\frac{1}{2} \pi P_0$: and the multiplication is by $\cos 0\varpi$, or 1. But if in (1), the equivalent of (3), we make the obvious summation by substitution of

$$1 + \frac{a^{-1} - a^{-n-1}}{1 - a^{-1}} + \frac{a - a^{n+1}}{1 - a}, \text{ or } \frac{a^n + a^{-n} - (a^{n+1} + a^{-(n+1)})}{2 - (a + a^{-1})},$$

or

$$\frac{2 \cos n\varpi - 2 \cos (n+1)\varpi}{2 - 2 \cos \varpi}, \text{ or } \frac{\sin \frac{1}{2} (2n+1) \varpi}{\sin \frac{1}{2} \varpi},$$

and

$$\pi P_l = \int_0^\pi \left(\frac{\sin \frac{1}{2} (2n+1) \varpi}{\sin \frac{1}{2} \varpi} \right)^s \cos l\varpi d\varpi \dots (l)$$

for all whole values of l except $l=0$, in which case

$$\frac{1}{2} \pi P_0 = \int_0^\pi \left(\frac{\sin \frac{1}{2} (2n+1) \varpi}{\sin \frac{1}{2} \varpi} \right)^s d\varpi \dots (0).$$

Let A' be the power of the ratio of the sines in question. Then it is shown immediately that this function is never infinite, for if $\theta = w\pi \pm \phi$ (ϕ being small) $m\theta = mw\pi \pm m\phi$, and

$$\frac{\sin m\theta}{\sin \theta} = \pm, \text{ or } \mp \frac{\sin m\phi}{\sin \phi} = \pm m, \text{ when } \phi=0.$$

Now m being an odd number, as θ proceeds from 0 to $\frac{1}{2} \pi$, (its extreme value since θ is here $\frac{1}{2} \pi$), $m\theta$ proceeds through an odd number of right angles, in each of which the ratio may have an algebraical maximum or minimum, determined by the equation

$$\tan m\theta = m \tan \theta$$

for

$$\frac{d}{d\theta} \cdot \frac{\sin m\theta}{\sin \theta} = \frac{\cos m\theta \cdot \cos \theta}{\sin^2 \theta} (m \tan \theta - \tan m\theta),$$

which can only vanish when the last factor vanishes, and does not become infinite from $\theta=0$ to $\theta=\frac{1}{2} \pi$. There is a change from $+$ to $-$ in this differential coefficient from before to after $\theta=0$, indicating a maximum, and in the first right angle $m \tan \theta$ is always less than $\tan m\theta$. The whole continues negative till θ has so increased that $m\theta$ is out of the second right angle, but while $m\theta$ is in the third right angle (the tangent having become

Theory of
Pro-
babilities.

positive again) there is an angle for which $\tan m\theta = m \tan \theta$, and a minimum is indicated. Similarly, when $m\theta$ is in the fifth, seventh, &c. right angles, there are maxima and minima alternately. It remains to find superior and inferior limits for the values of θ which determine them.

Theory of
Pro-
babilities.

The first, a maximum, is when $\theta = 0$; for the second, $m\theta$ being in the third right angle, lies between π and $\frac{3}{2}\pi$, or

$$\text{For the second } \dots \theta > \frac{\pi}{m} < \frac{3}{2} \frac{\pi}{m}$$

$$\text{For the third } \dots \theta > \frac{2\pi}{m} < \frac{5}{2} \frac{\pi}{m}$$

$$\dots \dots \dots$$

$$\text{For the } m\text{th } \dots \theta > \frac{(m-1)\pi}{m} < \text{, or not } > \frac{\pi}{2}.$$

To find closer limits, observe that $m \tan \theta$ being always $> m\theta$ when $\theta < \frac{1}{2}\pi$, we must have in the cases under discussion $\tan m\theta > m\theta$; if, then, $m\theta$ be greater than $v\pi$, $\tan m\theta$ is also $> v\pi$, and $m\theta$ therefore greater than $v\pi + \frac{\pi}{4}$, for all tangents of angles between $v\pi$ and $v\pi + \frac{1}{4}\pi$ are less than unity, and therefore less than $v\pi$. That is, at the second value above mentioned, $m\theta$ is greater than $\frac{5}{4}\pi$; at the third, $m\theta$ is greater than $\frac{9}{4}\pi$, and so on.

Now, as to the value of the function itself, we have in the case of a maximum or minimum (for numerical values, neglecting signs)

$$\frac{\sin m\theta}{\sin \theta} = m \frac{\cos m\theta}{\cos \theta} = \frac{m}{\cos \theta \sqrt{1 + m^2 \tan^2 \theta}} = \frac{m}{\sqrt{\cos^2 \theta + m^2 \sin^2 \theta}} < \frac{1}{\sin \theta}, \text{ or } \frac{m}{m\theta} \cdot \frac{\theta}{\sin \theta}, \text{ which } < \frac{m}{m\theta} \cdot \frac{\pi}{2};$$

for it may readily be shown that $\theta \div \sin \theta$ is an increasing function of θ from $\theta = 0$ to $\theta = \frac{1}{2}\pi$, and therefore $\frac{1}{2}\pi$ is greater than any other value within those limits. Substituting for $m\theta$ any inferior limit, *a fortiori*, the last obtained disparity is increased; that is,

$$\text{At the second maximum* } \frac{\sin m\theta}{\sin \theta} < \frac{2}{5} m$$

$$\dots \text{ third } \dots < \frac{2}{9} m$$

$$\dots \text{ fourth } \dots < \frac{2}{13} m.$$

The maxima and minima of A' , or $(\sin m\theta \div \sin \theta)^s$, depend upon the same value of θ as those of A ; and the first value, when $\theta = 0$ is m^s ; the remaining values are severally less than $\left(\frac{2}{5}m\right)^s$, $\left(\frac{2}{9}m\right)^s$, &c.

Of these numerical maxima, it is evident that their values diminish with extreme rapidity when s is even a moderate whole number. If s be 10, the second is little more than the ten-thousandth part of the first. If s be 100, the second is a fraction .0000... of the first, where first significant figure is in the fortieth decimal place. Consequently, since $\sin m\theta \div \sin \theta$ is a maximum when $\theta = 0$, and becomes 0 when

$$\theta = \frac{\pi}{m}, \text{ or } \frac{2\pi}{m}, \text{ or } \frac{3\pi}{m}, \dots, \text{ or } \frac{1}{2}(m-1)\pi,$$

we have the equation $\left(\frac{\varpi}{2} = \theta\right)$,

$$\int_0^\pi A^s d\varpi = \int_0^{\frac{2\pi}{m}} A^s d\varpi + \int_{\frac{2\pi}{m}}^{\frac{4\pi}{m}} A^s d\varpi + \dots + \int_{\frac{(m-1)\pi}{m}}^\pi A^s d\varpi.$$

The first integration is made from a maximum to a vanishing value of A ; the second, &c. (with the exception of the last) from one vanishing value of A to the next: if, then, we apply the method in (64.), and call $Y_1, Y_2, \dots$ the maxima of A^s , we shall have

$$\int_0^\pi A^s d\varpi = Y_1 T_1 + Y_2 T_2 + \dots$$

$T_1, T_2, \dots$ being certain convergent series. But, owing to the very small value of $Y_2, Y_3, \dots$, as compared with Y_1 , the first of them only need be retained, or it is only necessary to integrate $A^s d\varpi$ from $\varpi = 0$ to the first value of ϖ , which gives $\sin(2n+1)\frac{\varpi}{2}$, or $\sin m\theta = 0$; that is, to $\varpi = \frac{2\pi}{2n+1}$, or $\theta = \frac{\pi}{m}$.

* We call them all *maxima*, because it is numerical value only which we are considering. Taking the alternate *numerical maxima* with their negative signs, they are algebraic minima.

Theory of
Pro-
babilities.

Let us then assume

$$y = \left(\frac{\sin m\theta}{\sin \theta} \right)^s \quad Y = m^s \log y = s \log \sin m\theta - s \log \sin \theta \quad \frac{y'}{y} = s \left(\frac{m}{\tan m\theta} - \frac{1}{\tan \theta} \right)$$

$$\frac{y'' y - y'^2}{y^3} = s \left(-\frac{m^2 (1 + \tan^2 m\theta)}{\tan^2 m\theta} + \frac{1 + \tan^2 \theta}{\tan^2 \theta} \right) = -s(m^2 - 1) + s \frac{\tan^2 m\theta - m^2 \tan^2 \theta}{\tan^2 m\theta \cdot \tan^2 \theta};$$

Theory of
Pro-
babilities.

of which the second term vanishes at every maximum except the first, when $\theta=0$, in which case, substituting $\theta + \frac{1}{3}\theta^3 + \dots$ for $\tan \theta$, &c., this same second term becomes $\frac{2}{3}s(m^2-1)$; so that at the first maximum we have $\frac{y''}{y} = -\frac{1}{3}(m^2-1)s$, and $-(m^2-1)s$ at every other.

Now since θ and $-\theta$ give the same values to A , and therefore to A' , we may integrate from $\theta=0$ to $\theta=\frac{\pi}{m}$, by taking the half of the approximate integral from $\theta=-\frac{\pi}{m}$ to $\theta=+\frac{\pi}{m}$, which is the integral taken between the two vanishing points which contain the maximum m' . This approximation (65.) is

$$\int_{-\frac{\pi}{m}}^{+\frac{\pi}{m}} A' d\theta = \sqrt{\pi} Y \sqrt{-\frac{2Y}{Y''}} = m' \sqrt{\frac{6\pi}{(m^2-1)s}};$$

therefore

$$\int_0^{\frac{\pi}{m}} A' d\theta = \frac{1}{2} m' \sqrt{\frac{6\pi}{(m^2-1)s}} = \int_0^{\frac{\pi}{m}} A' d\omega;$$

so that the term independent of a in (1) is very nearly expressed by dividing the preceding result by $\frac{1}{2}\pi$, and putting $2n+1$ for m , which gives

$$P_0 = (2n+1)' \sqrt{\frac{3}{2n(n+1)s\pi}},$$

a very near approximation, when s is a large number.

The passage to any other term is easily made by means of the integral in (81.) In the process, of which the preceding is an application, we have (66.) (since the maximum is when $\theta=0$, whence θ in this case is $0+\theta$ there; that is, θ is the same in both cases)

$$\theta = B_1 t = \sqrt{-\frac{2Y}{Y''}} \cdot t \text{ very nearly.}$$

And it may be easily shown that $A' \cos 2l\theta$ is a function with alternate positive and negative maxima, decreasing with great rapidity. But, without entering into this question, we have, from what immediately precedes,

$$\cos 2l\theta = \cos \left(2l \sqrt{\frac{6}{(m^2-1)s}} \cdot t \right) \text{ very nearly,}$$

$$A' = m' \varepsilon^{-t^2} \text{ (the fundamental hypothesis,)}$$

$$d\theta = \sqrt{\frac{6}{(m^2-1)s}} \cdot dt \text{ very nearly.}$$

Whence, on account of the smallness of A' after $\theta=\frac{\pi}{m}$, and the still greater smallness of $A' \cos 2l\theta$, we need only integrate from $\theta=0$ to $\theta=\frac{\pi}{m}$ instead of to $\theta=\pi$, which answers to integrating from $t=0$ to $t=\infty$, and gives

$$\int_0^{\frac{\pi}{m}} A' \cos 2l\theta \cdot d\theta = \sqrt{\frac{6}{(m^2-1)s}} m' \int_0^{\infty} \varepsilon^{-t^2} \cos \left(2l \sqrt{\frac{6}{(m^2-1)s}} \cdot t \right) \cdot dt$$

$$(81.) = \sqrt{\frac{6}{(m^2-1)s}} \frac{m' \sqrt{\pi}}{2} \varepsilon^{-\frac{6l^2}{(m^2-1)s}};$$

which (if we multiply by 2, then substitute ω for 2θ , and $2n+1$ for m , and use this integral, for reasons above stated, instead of integrating from $\omega=0$ to $\omega=\pi$) will, when divided by π , give P nearly. Or we have

$$P_l = \sqrt{\frac{3}{2n(n+1)s\pi}} (2n+1)' \varepsilon^{-\frac{3l^2}{2n(n+1)s}}.$$

(83.) We shall now proceed as in (74.) to express

$$S = P_{-l} + P_{-l+1} + \dots + P_{-1} + P_0 + P_1 + \dots + P_{l-1} + P_l;$$

as before, we have, supposing $P_0 + P_1 + \dots + P_{l-1} = \Sigma P_l$, to find $2\Sigma P_l - P_0 + 2P_l$ or

$$2 \left\{ \int_0^{\pi} P_l d\omega - \frac{1}{2} P + \frac{1}{12} \frac{dP}{d\omega} - \&c. \right\} - P_0 + 2P_l + \text{constant}; \quad (71.)$$

Theory of
Pro-
babilities.

and, if we suppose l^2 small with respect to n^2s , we may reject the differential coefficient, and we have, therefore, for the sum required,

$$2 \int_0^l P_l dl + P_l - P_0 + \text{constant};$$

which, if $l=0$ is to reduce the series to P_0 , (which is the case supposed,) requires that the constant $= P_0$, or we have

$$S = 2 \int P_l dl + P_l, \text{ or } \frac{(2n+1)^s \sqrt{6}}{\sqrt{n(n+1)s\pi}} \left\{ \int_0^l \varepsilon^{-\frac{3l^2}{2n(n+1)s}} dl + \frac{1}{2} \varepsilon^{-\frac{3l^2}{2n(n+1)s}} \right\}.$$

(84.) We now come to the application of the Theory of Probabilities to the estimation of the errors which may be expected in the results of observation.

The numerical result derived from any observation whatsoever must be expected to contain an error, depending for its magnitude upon the distinctness of the phenomenon itself, the general and individual qualities of the instrument employed, the habits and temperament of the observer, and similar circumstances. Each observation must be considered as a result most probably greater or less than the truth, and in the former case is said to be effected with a positive, in the latter with a negative, error.

In defining what we here mean by an *error*, it must be understood that we include only those variations from truth of which no account can be given, except that they are found to exist. Under any other conditions they cease to be errors, and become phenomena, the laws and causes of which are objects of inquiry. Thus, for instance, upon a principle analogous to that in (49.), if any circumstance connected with the observation excite a remark, that remark is itself a new observation, which must be taken into account. Suppose, for example, the numerical results of a set of observations continually increase, no one being less than its predecessor. The probabilities become insuperable, either that the phenomenon or the instrument is in a state of regulated change; something which was imagined to be constant is not constant; and the laws of a phenomenon present themselves for investigation, not the probable amount of a result. Nothing is to be called an error which is more likely to be of one sign than the other. Suppose an observer should find it to be the case, in comparing his observations, say of right ascensions of stars, with the results of a catalogue, that the transits he observes make the stars almost always pass the meridian too soon according to the catalogue, and seldom too late. He will then feel strongly assured, either that he is in the habit of noting phenomena too soon, or that the observer who formed the catalogue had a contrary habit, or that one or other of the instruments was not well fixed in the meridian, or that there is some permanent mistake in the method of reducing the results of the first catalogue to his own time, arising, it may be, from a yet undetected change in right ascensions, or from error of principle or computation. But if he only find a moderate excess of positive departures over negative ones, on comparing his results with those of the catalogue, it will be proper for him to try, by the method in (74.), what would have been the probability of such an excess upon the supposition that positive and negative departures were equally likely. If he find his observed event very improbable, then (77.) the supposition of the differences being really errors, in our sense of the word, is also very unlikely; and the contrary.

(85.) An instrument for observation consists of two parts; the observer himself, and the inert matter which he has put together for his purpose. The combination is subject to errors at each observation: but upon which part of the apparatus they are to be laid is a question which cannot be altogether settled. We suppose that the results of different observations do not differ much from each other; so that any one will be near to the truth, and the extreme differences will give some idea of the probable limits of error. But they cannot be made to furnish any presumption as to what is the law of probability of the error, until the most probable result of the observations has been obtained, as it should be, supposing the tendencies of the instrument to be entirely unknown. We may afterwards apply knowledge gained from a first set of observations to finding the (with that knowledge) most probable result of a second set: and here new circumstances may create new impressions and new probabilities. But, as there must be one set at least antecedent to any formation of opinion upon the instrument, it is to this set that we must first turn our attention.

(86.) By the *law of facility* of the errors is meant $\phi x dx$, which expresses the probability that, before an observation is made, its coming error will lie between x and $x+dx$: so that $\int \phi x dx$ between any limits will express the chance of the error lying between these limits. The cases which arise in practice are always those in which considerable error is extremely improbable, that is, ϕx is a function which diminishes rapidly as x increases. The most convenient mathematical representation of the law of facility is one which supposes any error, however great, positive or negative, to be *possible*, but errors of a certain magnitude to be so *improbable*, not that they may be rejected, but that they may be taken into account; the reason being, that the integrals which the subject will present are by that supposition made more manageable. If, then, a be an amount of error which we are almost certain of avoiding, it must have such a function ϕx for its law of facility, that $\int_{-a}^{+a} \phi x dx$ is very nearly the same as $\int_{-\infty}^{+\infty} \phi x dx$.

(87.) Considering an error as a disadvantage in proportion to its magnitude, we may, on the same principle as that in which we ascertain the value of a pecuniary risk, determine the total risk arising from all possible errors. If any sum might be gained between a and b , and if $\phi x dx$ were the chance of its lying between x and $x+dx$, the value of the contingent advantage would be $\int x \phi x dx$ from $x=a$ to $x=b$. If there might be gain or loss to any amount, the sum to be given or received, according as it is positive or negative, would be $\int_{-a}^{+a} x \phi x dx$. Similarly, where $\phi x dx$ expresses the law of facility of errors, the amount of error on which it would be most safe to reckon has the same expression. And this is called the mean risk of error: or, generally, the mean risk arising from all the errors between a and b is $\int x \phi x dx$ from $x=a$ to $x=b$. But, if we should ask for the probable mean n th power* of the error, it must be found from the expression $\int x^n \phi x dx$.

* Observe, that the most probable square, &c. of the error, and the square, &c. of the most probable error, are distinct things.

Theory of
Pro-
babilities.

Theory of
Pro-
babilities.

(88.) Now no previous impression which we have of the law of facility is better worth attention than this, that we expect the most probable n th power of the error to be a finite quantity, whatever n may be. No one who has ever observed, or seen the results of observation, will admit any other axiom. If the errors of all the transit observations that ever were made, a tenth of a second counting as unity, had their n th powers *arithmetically* added together, and if the sum were divided by the number of observations, which would be an approximation to the order of magnitude of the probable n th power, it would appear as unlikely to an observer that the result should be as great as 10,000ⁿ as that he himself should mistake by ten minutes the mere noting of a single phenomenon. We shall take the impression as good for this much at least; namely, to make it worth while to inquire what are the laws of facility for which it is true that $\int_0^\infty x^n \phi x dx$ is finite for all values of n , on the supposition that ϕx is positive and less than unity for all values of x . This requires that $x^n \phi x$ should diminish without limit as x increases without limit; for if $x^n \phi x$ were always greater than a , from and after $x=p$, then $\int_p^\infty x^n \phi x dx$ would be greater than $\int_p^\infty a dx$, and would be either infinite (which is against the supposition) or negative, which cannot be, seeing that the most probable of all the positive errors must be positive. We have, then, to investigate a class of functions for which $x^n \phi x = 0$ when $x = \infty$, for all values of n . By the common rules of the Differential Calculus, we must have in such a case

$$0 = x^n \phi x = \frac{n \cdot n-1 \cdot n-2 \dots 3 \cdot 2 \cdot 1}{\frac{d^n}{dx^n} \frac{1}{\phi x}} \text{ for all values of } n, x \text{ being infinite.}$$

Consequently $\frac{1}{\phi x}$ and all its differential coefficients must be infinite when x is infinite. The most general of known

and ordinary forms which satisfies such a condition is $\varepsilon^{\psi x} \cdot \chi x$, where ψx and x become infinite together, and which may be represented in the form $\varepsilon^{ax+bx^2+\dots} \{A+Bx+\dots\}$, which may be reduced to $\varepsilon^{ax} \{A'+B'x+\dots\}$. This is not the most general form which might be given; but it will be sufficient for our purpose. This being the reciprocal of ϕx , we have for ϕx the form $\varepsilon^{-ax} \{A''+B''x+\dots\}$, and if positive and negative errors of the same magnitude are to be equally likely, we must give ϕx the form $\varepsilon^{-ax^2} (A+Bx^2+\dots)$. In all these cases a must be positive.

If we assume the form just obtained for ϕx , it is evident that $\int_0^\infty x^n \phi x dx$ is a series of terms of the form $K \int_0^\infty x^p \varepsilon^{-ax^2} dx$, where p is always odd or always even. And from the general formulæ,

$$\begin{aligned} \int_0^\infty x^{2n+1} \varepsilon^{-ax^2} dx &= \frac{1}{2} \frac{1 \cdot 2 \cdot 3 \dots n}{a^{n+1}} & \int_0^\infty x^{2n} \varepsilon^{-ax^2} dx &= \frac{\sqrt{\pi}}{2} \frac{1 \cdot 3 \cdot 5 \dots 2n-1}{2^n a^{n+\frac{1}{2}}} \\ \int_0^\infty x^{2n+1} \phi x dx &= \frac{A}{2} \frac{1 \cdot 2 \cdot 3 \dots n}{a^{n+1}} + \frac{B}{2} \frac{1 \cdot 2 \cdot 3 \dots n+1}{a^{n+2}} + \dots & \int_0^\infty x^{2n} \phi x dx &= \frac{\sqrt{\pi}}{2} \left\{ \frac{A}{2^n} \frac{1 \cdot 3 \dots 2n-1}{a^{n+\frac{1}{2}}} + \frac{B}{2^{n+1}} \frac{1 \cdot 3 \dots 2n+1}{a^{n+\frac{3}{2}}} + \dots \right\} \end{aligned}$$

These series may be made convergent in an infinite number of different ways, by giving a sufficiently rapid diminution to $A, B, C, \dots$: so that we have an extensive class of possible laws of facility which will satisfy all our preconceived notions of the conditions necessary to be fulfilled. (See also remark at the end.)

(89.) When we have no reason to prefer any one observation to any other, the universal practice is to take the average or arithmetical mean of the results, and to consider that average as the most probable value of the numerical phenomenon in question. Where positive and negative errors are equally likely, we may show, as in (74.), that the most probable sum of errors (before the observations are made) is 0; or L being the true result, and A_n that of the n th and last observation, both unknown, that $\Sigma (A_p - L) = 0$ is the most probable equation, or

$$L = \frac{1}{n} \Sigma A_p. \text{ We therefore conclude, that if it were requisite to construct a method of treating the observations}$$

before they were made, the best method would be that of the average. But when the observations *have been made*, and the errors, though unknown, are no longer contingencies, the position of the observer is changed. It is no longer necessary to reason as upon an urn containing known balls, from which drawings are to be made, since they have been made, and the question is, what, judging by the drawings, are the probable contents of the urn. Let ϕe represent the comparative probability of an error e being made at a single observation. If, then, x had been the true result of the observations $A_1, A_2, \dots, A_n$, the antecedent probability of the observed event, namely, the succession of errors $A_1 - x, A_2 - x, \&c.$ would have been $\phi(A_1 - x) \phi(A_2 - x) \dots \phi(A_n - x)$, which call

y . And the probability resulting from the observed event to the value of x will be (19.) $\frac{y dx}{\int y dx}$, taken between the

extreme limits of the possible value of x ; for every different value of x may be considered as a possible state of things under which the observed event might have happened. If, as in (86.), we suppose $-\alpha$ and $+\alpha$ to be the limits of the value of x , and make $H = 1 \div \int_{-\alpha}^{+\alpha} y dx$, we have $H y dx$ for the probability that x is true. Now the absolute truth is not the object of investigation. Let L be the value which, whatever may be the reason, we take as the most probable result. Consequently $L - x$ is the error, and the risk of this error is exactly that of x being true, or $(L - x) H y dx$ is the disadvantage.* The sum of all the possible disadvantages is $\int_{-\alpha}^{+\alpha} (L - x) H y dx$, which can be made equal to nothing by taking for L the value $\frac{\int_{-\alpha}^{+\alpha} x y dx}{\int_{-\alpha}^{+\alpha} y dx}$; that is, given the law of facility of error, the most probable value, or at least the value which gives the least total risk of error, is determined. Now if we represent the law of facility ϕe by $\varepsilon - \psi(e^2)$, where ψ is not ambiguous in form,

* Meaning the opposite of advantage, as used when we say that the advantage of an even chance of £2 is £1.

Theory of
Pro-
babilities.

which may be made to include every case in which positive and negative errors are equally likely; and if, more-
over, we assume $x = L + z$, we have

Theory of
Pro-
babilities.

$$y = \varepsilon - \psi(A_1 - x)^2 - \psi(A_2 - x)^2 - \dots = \varepsilon - M - 2Nz - Pz^2 - \dots$$

$$M = \sum \psi(L - A)^2 \quad N = \sum \{(L - A) \psi'(L - A)^2\} \quad P = \sum \{\psi'(L - A)^2 + 2(L - A)^2 \psi''(L - A)^2\}, \text{ \&c.}$$

$$L = \frac{\int_{-\infty}^{+\infty} (L + z) \varepsilon - M - 2Nz - \dots dz}{\int_{-\infty}^{+\infty} \varepsilon - M - 2Nz - \dots dz}, \text{ or } \int_{-\infty}^{+\infty} z \varepsilon - M - 2Nz - Pz^2 - \dots dz = 0;$$

which is the necessary condition of a law of facility, in which positive and negative errors are equally likely, being coexistent with any result of *observations actually made*, and such that the sums of all the risks of error is nothing. The preceding condition is evidently satisfied *per se*, if there be no odd powers of z in the exponent: but the following consideration will allow us to disregard them all except Nz . Since the observations are near together, and since the supposed law of facility is such, that the probability of the result not lying among them is excessively small, y becomes excessively small when z is not very small; that is, the part of the integral $\int_{-\infty}^{+\infty} zy dz$, which arises from all the sensible values of z , is inconsiderable compared with that which arises from the small values of z . Hence the terms following Pz^2 may be neglected; for when z is small they are of inconsiderable effect, when z increases the whole becomes inconsiderable. But we have

$$\int_{-\infty}^{+\infty} z \varepsilon - M - 2Nz - Pz^2 dz = \varepsilon^{-M + \frac{N^2}{P}} \int_{-\infty}^{+\infty} \varepsilon - \left(\frac{N}{\sqrt{P}} + \sqrt{P}z \right)^2 z dz = -\frac{N\sqrt{\pi}}{P^{\frac{3}{2}}} \varepsilon^{-M + \frac{N^2}{P}};$$

whence $N=0$ is the necessary condition of the law of facility; or $\sum (L - A) \psi'(L - A)^2 = 0$. This is a relation between the value of L and the form of ψ , which cannot be explicitly deduced, but it leads to the following remark, namely, that the average of observations is not *necessarily* the most probable result, when the observations themselves are given, though it is so for unknown or prospective observations. If, then, we assume the average as the most probable result, we do either assume a law of facility, or the necessity of choosing one law out of a particular class, defined by the preceding equation. We now proceed to inquire what this law must be. Let us

suppose the preceding equation to be satisfied in all cases by $L = \frac{1}{s} \sum (A_1 + \dots + A_s)$, s being the number of observations. Let i of the observations give A_1 , and the remaining $s-i$ give A_2 , then we have

$$L = \frac{i A_1 + (s-i) A_2}{s}, \quad L - A_1 = (s-i) \frac{A_2 - A_1}{s}, \quad L - A_2 = i \frac{A_1 - A_2}{s}; \text{ make } A_1 - A_2 = \Delta;$$

$$i(s-i) \frac{\Delta}{s} \psi' \left\{ (s-i)^2 \frac{\Delta^2}{s^2} \right\} - (s-i) i \frac{\Delta}{s} \psi' \left\{ i^2 \frac{\Delta^2}{s^2} \right\} = 0, \text{ or } \psi' \left\{ (s-i)^2 \frac{\Delta^2}{s^2} \right\} = \psi' \left\{ i^2 \frac{\Delta^2}{s^2} \right\};$$

which being true for all values of s and i , gives $\psi'x = \text{constant}$, or $\psi x = cx + c'$. And this may be shown to be true for s *different* observations, since N is then $\sum c(L - A)$, or $c(nL - \sum A)$, which is $=0$. Consequently, the chance of an error lying between e and $e+de$ is $\varepsilon - ce^2 - c'de$, or $c''\varepsilon - ce^2 de$; and since this integrated from $-\infty$ to $+\infty$ must give 1, we have $c''\sqrt{\pi} \div c = 1$, whence the law of facility of errors, which gives to the average of observed results the sum of all the risks of positive error = the same for negative errors, may be thus expressed:

The probability of the error of a single observation lying between p and q is $= \sqrt{\frac{c}{\pi}} \int_p^q \varepsilon^{-cx^2} dx$.

(90.) The supposition of the real law of facility (which depends on the instrument, the observer, &c.) being a consequence of a common notion as to the best method of treating results, is altogether out of the question as an assumption, upon its own merits; but we must observe, 1. That the indeterminateness of the constant c will allow of an adjustment of this law, with a considerable degree of nearness, to any law which can be proposed. 2. That, as we shall hereafter see, *the assumption of this law will give in fact a mathematical approximation to any other law, and the more nearly the greater the number of observations in question.*

(91.) Returning to the suppositions in (89.) we have now (for s observations)

$$y = H \left(\frac{c}{\pi} \right)^{\frac{s}{2}} \varepsilon^{-c \sum (x - A)^2}, \text{ and is of the form } H' \varepsilon^{-csu^2}, \text{ where } x = \frac{\sum A}{s} + u.$$

This, for any value of u , is the presumption which the collective observations give to the supposition that u is the error of the average. Integrated from $-\infty$ to $+\infty$ it gives 1, whence $H' = \sqrt{cs \div \pi}$, and

The probability of an average having an error between p and q is $\sqrt{\frac{cs}{\pi}} \int_p^q \varepsilon^{-csu^2} du$.

(92.) The infinitely small probabilities of two sets of s and s' observations giving the exact truth are as $\sqrt{s}$ to $\sqrt{s'}$; and since we have

$$\sqrt{\frac{cs}{\pi}} \int_{-\infty}^{+\infty} \varepsilon^{-csu^2} du = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{+\infty} \varepsilon^{-t^2} dt, \quad \sqrt{cs}u = t, \quad \sqrt{cs}du = dt,$$

the errors which different sets of observations have the same chance of not exceeding are inversely as the values of

Theory of
Pro-
babilities.

$\sqrt{cs}$: for different sets of the same observer, inversely as the square roots of the numbers of observations; and for the same numbers of observations by different observers, inversely as the square roots of the values of c . Hence the probability of s observations, averaged, giving an error between $\pm e$ is the same as that of a single observation giving one between $\pm \sqrt{s} \cdot e$. Suppose, for instance, the extreme of error on which it is worth while to reckon in the noting of the passage of a star over a single wire of a transit instrument to be two-tenths of a second, or 0.2 , then if $\sqrt{5}e = .2$, we have $e = .09$, or nine-hundredths of a second is as improbable in the mean of five wires, as two-tenths of a second on one wire. The present Astronomer Royal,* speaking of his observations at Cambridge, remarks that he has "been accustomed to consider the error of a transit over seven wires as not greater than 0.06 ." Now $\sqrt{7} \times .06 = .158$ nearly, which is the consequent estimate of the error at a single wire.

Theory of
Pro-
babilities.

(93.) The multiplication of indifferent observations does not give results so much exceeding in value those of a few good ones as is sometimes supposed. Let there be 10,000 observations each as likely to have ± 1 for the limits of error as 100 others to have each an error lying within ± 1 . In the first, $\sqrt{10,000} \cdot e = 1$, or $e = .01$; in the second, $\sqrt{100}e = .1$, or $e = .01$; that is, the first set does not exceed the second in merit.

(94.) In Table I. it is not $\int_{-a}^{+a} \varepsilon^{-t^2} dt$ which is given, but $\int_a^\infty \varepsilon^{-t^2} dt$, the two being connected by the equation

$$\int_{-a}^{+a} \varepsilon^{-t^2} dt = \sqrt{\pi} - 2 \int_a^\infty \varepsilon^{-t^2} dt, \text{ or } P_e = 1 - \frac{2}{\sqrt{\pi}} I(\sqrt{c}e),$$

where P_e denotes the probability of the error lying within $\pm e$ in a single observation, and $I(\sqrt{c}e)$ means the number opposite to $\sqrt{c}e$ in Table I. If P_e can be ascertained, c can be found by inverse process from the Table.

And it will facilitate all operations with these Tables to remember that $\frac{1}{2}\sqrt{\pi}$ is itself $I(0)$, being $\int_0^\infty \varepsilon^{-t^2} dt$.

For instance, let us assume it as 4 to 1 that the error on a single wire of a transit does not exceed $\pm .158 (=e)$,

or $P_e = \frac{4}{5}$. We have then

$1 - P_e = .2$	$\log \bar{1}.30103$	$.9062$	$\log \bar{1}.95722$
$\frac{1}{2}\sqrt{\pi}$, or $I(0)$	$I(0) \log \bar{1}.94754$	$e = .158$	$\log \bar{1}.19866$
$\sqrt{c}e = .9062$	$I(\sqrt{c}e) \bar{1}.24857$		$\bar{0}.75856$
			$\underline{2}$
		$c = 32.89$	$\bar{1}.51712$

(95.) If in (91.) we suppose all the different observations to have been made under different laws of facility, whose constants are $c_1, c_2, \&c.$, the same process will give

$$\frac{\sum cA}{\sum c} \text{ for the average; } \sqrt{\frac{\sum c}{\pi}} \int_{-e}^{+e} \varepsilon^{-\sum c \cdot u^2} du \text{ for the chance of an error between } \pm e,$$

which substitutes

$$\frac{c_1 A_1 + c_2 A_2 + \dots + c_s A_s}{c_1 + c_2 + \dots + c_s} \text{ instead of } \frac{A_1 + A_2 + \dots + A_s}{1 + 1 + \dots + 1}.$$

This observers call giving different *weights* to the observations, and say that the weight of A_1 is to that of A_2 in the proportion of c_1 to c_2 . They are also in the habit of assigning weights by judging of the relative goodness of observations from the impressions on their minds at the time of observing. The soundness of this practice entirely depends upon the truth of the proposition which it tacitly assumes, namely, that there is a high probability that the observation which the observer *thinks* the better of two *is* the better. We cannot either confirm or refute this notion; but the practice derived from it should be used with great caution.

We may, however, call the constant c the *specific weight* of the observations to which it applies, and $\sum cA \div \sum c$ the *weighted mean*; and thus we may express the following theorem: the weight of a weighted mean is the sum of the weights of its component observations.

(96.) If we consider both the positive and negative errors, the most probable individual result of a coming observation is that the error should be nothing, and the most probable risk of error in an average is also nothing, since $\int_{-\infty}^{+\infty} x \cdot \phi x \cdot dx = 0$. But if we consider positive errors alone, we find the risk of error to be $\int_0^\infty x \phi x dx$, which,

when $\phi x = \sqrt{\frac{c}{\pi}} \varepsilon^{-cx^2}$, becomes $\frac{1}{2\sqrt{c\pi}}$. This is what Laplace calls *l'erreur moyenne à craindre en plus*, and

the corresponding error *en moins* is of the same magnitude with a different sign. We shall call it the *risk* of the observation, the sign of the error not being considered. It is what a man should in equity pay for being relieved of the liability of losing any possible sum, under such circumstances that the chances of the loss lying between x and $x+dx$ is $\sqrt{\frac{c}{\pi}} \varepsilon^{-cx^2} dx$. It appears, then, that the risk of an observation is inversely as the square root of the specific weight.

(97.) The average $\frac{1}{s} \sum A$ is evidently the value of x which makes $\sum (x - A)^2$ a minimum. If x be assumed as

* *Memoirs of the Royal Astronomical Society*, vol. vi. p. 97.

Theory of
Pro-
babilities.

the probable truth, then $x-A$ is the error of A , or the *method of averaging* is a particular case of the *method of least squares*, meaning the method by which such a result is obtained as will make the sum of the squares of the errors the least possible. And the weighted mean is the value of x , which makes $\sum c(x-A)^2$ a minimum. If we consider every determination as the solution of an equation, the case we have discussed is simply that of $x=a$, or $x-a=0$, where a is determined by observation. But let us suppose the equation in question to be $px+h=b$, where p , h , and b are to be determined by observation. We are not now at liberty to form the value of x , namely $(b-h)\div p$, and to proceed as before; for the chance of x thus obtained is a complicated function of the separate possibilities of error of p , h , and b . Two terms of an equation which is subject to error are not to be combined without considering the risk of the result, and the proper method by which it ought to be deduced from the risks of the components.

Theory of
Pro-
babilities.

(98.) Let $f(x_1, x_2, x_3, \dots)$ be a function of $x_1, x_2, \&c.$, which are to be severally observed. We shall confine ourselves to the case of three variables, and inquire what is the risk of the expression. From any number of observations obtain approximate values a_1, a_2, a_3 , differing from the truth by quantities of the same order as the risks of the several species of observations. Then the correction to be applied to $f(a_1, a_2, a_3)$ is of the form $m\Delta x_1 + n\Delta x_2 + p\Delta x_3 + \dots$ if $x_1 = a_1 + \Delta x_1, \&c.$, and we need only consider terms of the first order. Let θ_1, θ_2 , and θ_3 be the errors of Δx_1 or $x_1, \&c.$, then $m\theta_1 + n\theta_2 + p\theta_3$ is the error of f very nearly: and the probability of this lying between r and $r+dr$, or of $\frac{m}{p}\theta_1 + \frac{n}{p}\theta_2 + \theta_3$ lying between $\frac{r}{p}$ and $\frac{r}{p} + d \cdot \frac{r}{p}$ is the sum of every possible value of

$$\frac{\sqrt{c_1 c_2 c_3}}{\pi \sqrt{\pi}} e^{-c_1 \theta_1^2 - c_2 \theta_2^2 - c_3 \theta_3^2} d\theta_1 d\theta_2, \text{ which consists with } \frac{m}{p}\theta_1 + \frac{n}{p}\theta_2 + \theta_3 = \frac{r}{p} \dots \dots (1)$$

Write m instead of $\frac{m}{p}$, &c. for the present, substitute $\theta_3 = r - m\theta_1 - n\theta_2$; we want then

$$dr \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} e^{-(A\theta_1^2 + 2B\theta_1\theta_2 + C\theta_2^2) + 2D\theta_1 + 2E\theta_2 + F} d\theta_1 d\theta_2 \quad \left| \begin{array}{lll} A = c_1 + c_3 m^2 & B = c_3 m n & C = c_2 + c_3 n^2 \\ D = c_3 r m & E = c_3 r n & F = -c_3 r^2 \end{array} \right.$$

$$\text{Assume} \quad v = \theta_1 + \frac{B}{A} \theta_2, \quad M = \frac{AC - B^2}{A}, \quad N = \frac{AE - BD}{A};$$

which reduces the exponent to $-M\theta_2^2 - 2N\theta_2 - Av^2 + 2Dv + F$, in which the variables are separated. Let $dv = d\theta_1$, or let v and θ_1 vary together in the first integration, and integrate, which gives

$$dr \int_{-\infty}^{+\infty} e^{-M\theta_2^2 - 2N\theta_2} d\theta_2 \int_{-\infty}^{+\infty} e^{-Av^2 + 2Dv + F} dv = \frac{\pi dr}{\sqrt{AM}} e^{F + \frac{D^2}{A} + \frac{N^2}{M}} = \frac{\pi dr}{\sqrt{AC - B^2}} e^{F + \frac{CD^2 + AE^2 - 2BDE}{AC - B^2}}.$$

1. Substitute for $A, \&c.$ their values; and 2. restore $\frac{r}{p}$ for r , $\frac{dr}{p}$ for dr , &c.; which gives for (1) above

$$1. \frac{\sqrt{c_1 c_2 c_3} dr}{\sqrt{\pi} (c_1 c_2 + c_2 c_3 m^2 + c_3 c_1 n^2)^{\frac{1}{2}}} e^{-\frac{c_1 c_2 c_3 r^2}{c_1 c_2 + c_2 c_3 m^2 + c_3 c_1 n^2}}; \quad 2. \sqrt{\frac{V}{\pi}} e^{-Vr^2} dr, \quad V^2 = \frac{c_1 c_2 c_3}{c_1 c_2 p^2 + c_2 c_3 m^2 + c_3 c_1 n^2};$$

and the risk required is

$$\frac{1}{2\sqrt{V\pi}} = \frac{1}{2\sqrt{\pi}} \sqrt{\frac{m^2}{c_1} + \frac{n^2}{c_2} + \frac{p^2}{c_3}},$$

or the squared risk of a sum is the sum of the squared risks of its components. For the risk of Δx_1 being $1 \div 2\sqrt{c_1\pi}$, that of $m\Delta x_1$, m not being subject to error, is $m \div 2\sqrt{c_1\pi}$, and so on. This theorem applies to any number of variables, for the preceding shows that, by considering a sum of two terms as one observed result, instead of its components as two observed results, we must give to the result the risk expressed by the square root of the sum of the squares of the risks of the components; and the converse. Whence the general theorem readily follows. And we see also that the risk of any function f is that of $\frac{df}{dx_1} \cdot x_1 + \frac{df}{dx_2} \cdot x_2 + \dots$, where the partial differential coefficients are considered as given, and $x_1, x_2, \&c.$ subject to error. Hence, if we denote by $\rho f(x_1, x_2, \dots)$ the risk of $f(x_1, x_2, \dots)$, we have

$$\begin{aligned} \rho(x_1 + x_2 + \dots) &= \sqrt{(\rho x_1)^2 + (\rho x_2)^2 + \dots} & \rho \sum ax &= \sqrt{\sum a^2 (\rho x)^2} & \rho(xy) &= \sqrt{x^2 (\rho y)^2 + y^2 (\rho x)^2} \\ \rho\left(\frac{x}{y}\right) &= \sqrt{\frac{1}{y^2} + \frac{x^2}{y^4}} \cdot \rho x, \text{ if } \rho x = \rho y & \rho \frac{x_1 + \dots + x_s}{y_1 + \dots + y_s} &= \sqrt{\frac{s}{(\sum y)^2} + \frac{s(\sum x)^2}{(\sum y)^4}} \cdot \rho x. \end{aligned}$$

(99.) But if the above method be incautiously used, we become liable to the mistake of supposing the same variable determined by different observations in different parts of the same expression. For instance, the risk of xy being as just ascertained, that of $x+xy$ is $\sqrt{(\rho x)^2 + x^2 (\rho y)^2 + y^2 (\rho x)^2}$; but treating $x+xy$ as one expression, which has the partial differential coefficients $1+y$ and x , we find its risk to be $\sqrt{(1+y)^2 (\rho x)^2 + x^2 (\rho y)^2}$. Both are correct on their different suppositions: in the first we observe xy , and then x , and take the sum, the observations by which x is determined in xy and in x not being the same; but in the second we observe x and y , and from these values we compute $x+xy$. The risks are different in the two cases, and, as might be supposed, that of the first process is the less of the two; there being a chance of compensation in the first, which does not

Theory of Probabilities. exist in the second. Similarly, the risk of $2x$ is $2\rho x$, if x be observed, and $2x$ computed; but the risk of $x+x$, Theory of Probabilities, where both are observed, is only $\sqrt{2} \cdot \rho x$; and that of $x-x$ is the same.

(100.) We have hitherto considered the mean risk of error, to which a probable approximation might be made by taking the average amount of a large number of errors. The name of the *probable* error has sometimes been given to this result, but incorrectly. If by probable error be meant the most probable of all errors, the answer should be nothing, or the correct truth is individually more probable than any given error. At the same time, if we take the common meaning of the word probable (that is, more likely than not), we see that there is a certain amount of error positive or negative, which is probable, all lower amounts being improbable. For c being the

specific weight, if we determine e , so that $\sqrt{c/\pi} \int_{-e}^{+e} e^{-cx^2} dx = \frac{1}{2}$, we have the following theorem: it is exactly an even chance that the error lies between $+e$ and $-e$; more than an even chance that it lies between $e+e'$ and $-e-e'$; and less than an even chance that it lies between $e-e'$ and $-e+e'$. In calling e , thus obtained, the probable error, we mean then that any less superior limit of error is improbable, or any greater inferior limit. It is improbable that the error should be less than $e-e'$, or that it should be greater than $e+e'$.

The solution of the equation $\sqrt{\frac{1}{\pi}} \int_{-e}^{+e} e^{-x^2} dx = \frac{1}{2}$ gives $e = .4769360$;

consequently, (92.), we have $\frac{.4769360}{\sqrt{c}} = \text{probable error to specific weight } c$; and the probable error to the mean risk ρ is $1.690694 \times \rho$.

(101.) The distinction between the mean risk of error and the probable error is exactly analogous to the one for want of which the *mean duration* of life has been called the *expectation* of life in English Tables. The mean duration of life is found practically by summing the number of years enjoyed by a large number of persons of the same age: theoretically, it is $\int x \phi x dx$, where, of a very large number of persons attaining the age $a+x$ (a being the common age of commencement) ϕx represents the proportion which those who die between the ages of $a+x$ and $a+x+dx$ bear to those who began at the age a : the limits being from $x=0$ to $x=$ the greatest possible term of survivorship. This is the average duration of life; but it is not therefore the term of existence which each of the individuals may *expect*; that is to say, it is not the term through which each is as likely to live as not. For the proportion surviving at x years from the epoch of commencement is evidently $1 - \int_0^x \phi x \cdot dx$, and the value of x which makes this $= \frac{1}{2}$ is the probable life, and is what should have been called the *expectation* of life.

In De Moivre's celebrated hypothesis the two coincide; in the Northampton Table, which very much resembles it at the ages of adult youth and manhood, the two are nearly the same: in the Carlisle Table there is sensible difference, as will appear by the following comparison:

Age.	Northampton.		Carlisle.	
	Mean duration.	Probable life.	Mean duration.	Probable life.
20	33.4	33.3	41.5	44.8
30	28.3	28.1	34.3	36.6
40	23.1	22.7	27.6	28.9
50	18.0	17.5	21.1	21.6

(102.) We have dwelt thus much upon one law of errors, because, as already observed, it is not only the law which is necessarily connected with the *assumption* of the average of observations made and finished, but also the approximate result of any other supposition which preserves the essential conditions (88.). This we now proceed to show.

That we may pass from finite to infinite, as in (45.), let all the possible errors be multiples of θ ; and to preserve general terms, which may render the process more perceptibly applicable to other questions, let counters be thrown into an urn, marked $-n\theta, -(n-1)\theta, \dots, -\theta, 0, \theta, \dots, (n-1)\theta, n\theta$, the number of counters of each

mark $x\theta$, being proportional to $\psi\left(\frac{x}{n}\right)$ the comparative probability of that error; the greatest positive and negative errors being of course $\pm n\theta$.

Then to express that one of these errors must appear, we have $\sum \psi\left(\frac{x}{n}\right) = 1$, the sign $\sum$ extending from $x=-n$ to $x=+n$. And if s drawings be made, and the result of each drawing restored before proceeding to the next, the probability of the sum of the s drawings, attending to their signs, being exactly $l\theta$, is the coefficient of a^l in the development of

$$\left\{ \psi\left(\frac{-n}{n}\right)a^{-n} + \psi\left(\frac{-n-1}{n}\right)a^{-(n-1)} + \dots + \psi\left(\frac{0}{n}\right) + \psi\left(\frac{1}{n}\right)a + \dots + \psi\left(\frac{n}{n}\right)a^n \right\}^s$$

or, which is the same thing, the term independent of l in the preceding development multiplied by $a^l + a^{-l}$. If then, as in (82.), we make $a + a^{-1} = 2\cos\omega$, and if positive and negative errors of the same magnitude be equally likely, or if $\psi(-z) = \psi(+z)$, we find by integration for the coefficient in question

$$\frac{1}{\pi} \int_0^\pi \cos l\omega d\omega \left\{ \psi\left(\frac{0}{n}\right) + \psi\left(\frac{1}{n}\right) \cdot 2\cos\omega + \dots + \psi\left(\frac{n}{n}\right) \cdot 2\cos n\omega \right\}^s$$

Theory of
Pro-
babilities.

Expand $\cos \varpi$, &c. in the term in $\{ \}$; the term containing ϖ^z in that expression is

$$\pm \frac{2\varpi^z}{2.3\dots z} \left(\psi\left(\frac{1}{n}\right) \cdot 1^z + \psi\left(\frac{2}{n}\right) 2^z + \dots + \psi\left(\frac{n}{n}\right) \cdot n^z \right).$$

Theory of
Pro-
babilities.

(103.) When n increases without limit, and θ decreases without limit, let E be the greatest error (a given quantity); so that $n\theta = E$: and let the sum of the drawings, $l\theta$, be always $= L$. And as the probabilities of

individual errors diminish in such case without limit, let $\psi\left(\frac{x}{n}\right)$ be written $\theta\phi\left(\frac{X}{E}\right)$, where $X = x\theta$: the ultimate

law being that the probability of a single drawing lying between p and q is $\int \phi\left(\frac{X}{E}\right) dX$ between these limits;

for θ being $(x+1)\theta - x\theta$, is the difference between consecutive values of X , or is dX . Again, as l increases, let ϖ diminish without limit, but in such manner that $l\varpi = Lv$, which is a fixed quantity throughout the preliminary transformations, but which, when we come to integrate with respect to ϖ , gives $Ldv = l d\varpi$, or $l\theta \cdot dv = l d\varpi$, or $d\varpi = \theta dv$. We have also $\varpi = v\theta$; consequently, as ϖ , &c. diminish, the limits of v answering to those of ϖ (0 and π) become 0 and ∞ . Make these substitutions in the last expression of (102.), which becomes

$$\pm \frac{2v^z \theta^z}{2.3\dots z} \left\{ \theta\phi\left(\frac{\theta}{E}\right) \cdot 1^z + \dots + \theta\phi\left(\frac{E}{E}\right) \cdot n^z \right\}, \text{ or } \pm \frac{2v^z}{2.3\dots z} \left\{ \theta\phi\left(\frac{\theta}{E}\right) \cdot \theta^z + \dots + \theta\phi\left(\frac{E}{E}\right) \cdot (n\theta)^z \right\},$$

the limit of which is
$$\pm \frac{2v^z}{2.3\dots z} \int_0^E dX \cdot \phi\left(\frac{X}{E}\right) X^z, \text{ or } \pm \frac{2v^z E^{z+1}}{2.3\dots z} \int_0^1 \phi x \cdot x^z \cdot dx$$

On this we remark; 1. That to render the last expression in (102.) perfectly general, the last but one should have $\psi\left(\frac{0}{n}\right)$ altered into $2\psi\left(\frac{0}{n}\right)$, but the term so added decreases without limit. 2. That if the greatest possible error be infinite, as, with the remark in (86.), it may be, the preceding appears to fail; but it may readily be transformed thus. Let $\phi\left(\frac{X}{E}\right)$ be written $\chi(X)$; the integral in $\{ \}$ of the transformation becomes $\int_0^E \chi(X) \cdot X^z dX$, or, by the supposition, $\int_0^\infty \chi(X) \cdot X^z dX$. Whence the term in question becomes $2v^z \div 2.3\dots z \times \int_0^\infty \chi(X) X^z dX$; or, in the processes following, if we would pass from the supposition of limited errors to that of unlimited errors, we must write unity for E , except where it is the limit of an integral, in which case we must write ∞ for E .

Let $\int_0^\infty \phi x \cdot x^z \cdot dx$, or $\int_0^\infty \chi(X) X^z dX$, as the case may be, be called $k^{(z)}$, except only where $z=0$, in which case let $k=2\int_0^\infty \phi x \cdot dx$. (We preserve the notation of Laplace.) That is, let $k=2\int_0^\infty \phi x \cdot dx$, $k'=\int_0^\infty \phi x \cdot x dx$, &c. Substitute in the last but one of (102.) Lv for $l\varpi$, θdv for $d\varpi$, &c., and the probability of the sum of s drawings giving L is

$$\frac{\theta}{\pi} \int_0^\infty \cos Lv \left\{ Ek - \frac{2E^3 v^2}{2} k'' + \frac{2E^5 v^4}{2.3.4} k^{(4)} - \dots \right\}^s dv.$$

But

$$Ek = 2E \int_0^\infty \phi x \cdot dx = 2 \int_0^\infty \phi\left(\frac{x}{E}\right) dx = \int_{-E}^{+E} \phi\left(\frac{x}{E}\right) dx = 1,$$

since the error must lie between $-E$ and $+E$ (inclusive.) Assume $\varepsilon = t^2$ for the s th power just obtained, remembering that $Ek=1$, and if s be considerable ($s=10$ is sufficient), v can be expanded in a very convergent series of powers of t . Take the logarithms of both sides, and the first term of the expansion of that on the first side, which will give

$$s E^3 v^2 k'' = t^2 \text{ nearly, or the probability required is } \frac{\theta}{\pi} \int_0^\infty \cos\left(\frac{Lt}{\sqrt{sk''E^3}}\right) \cdot \varepsilon^{-t^2} \frac{dt}{\sqrt{sk''E^3}}.$$

Let

$$\beta = \frac{1}{4sk''E^3}, \text{ and this becomes } \theta \sqrt{\frac{\beta}{\pi}} \int_{-\infty}^{+\infty} \varepsilon^{-\beta L^2} dL,$$

which is the probability that the sum of s drawings will be L .

In this expression θ is dL , and thus we have $\sqrt{\frac{\beta}{\pi}} \int_{-\infty}^{+\infty} \varepsilon^{-\beta L^2} dL$ for the probability of the same lying between $\pm e$.

For L write Ls , and remember that the probability of the average drawing being L is the same as that of the sum being Ls , and make $c = \beta s^2$, we have then

$$\sqrt{\frac{c}{\pi}} \int_{-\infty}^{+\infty} \varepsilon^{-cL^2} dL, \text{ where } c = \frac{s}{4k''E^3}.$$

for the probability that the average of s drawings will lie between $\pm e$: that is to say, whatever the law of the errors may be, the results of the law already established as necessary when the average is assumed to be the most probable result, become more and more nearly true as the number of observations is increased, and are practically true for moderate numbers of observations. That is, we may proceed as if the specific weight of a single observation were $(4k''E^3)^{-1}$, the mean risk of error $\sqrt{k''E^3 \div \pi}$, and the probable error 1.69 of the last.

(104.) This method fails to show that the average of *two* observations is the most probable result; but if we go

Theory of Probabilities. back to (89.), we find that, on any supposition as to ψ , the substitution of an average of two results for L gives $N=0$; but not so for an average of three. So that if we diminish the accuracy of the preceding approximation by giving smaller and smaller values to s , the approximation does not become more and more defective; but when s has diminished to a certain extent, begins again to approach the true result of the same principles, as they would appear if the approximations were made perfectly rigorous, and finally coincides with them when $s=2$. Theory of Probabilities.

(105.) If in (103.) we write t^2 for cL^2 , in which case the limits of t are $\pm\sqrt{c}.e$, we have, making $T=\sqrt{c}.e$,

$$\frac{1}{\sqrt{\pi}} \int_{-T}^{+T} \varepsilon^{-t^2} dt, \text{ or } \frac{2}{\sqrt{\pi}} \int_0^T \varepsilon^{-t^2} dt$$

for the probability that the true result lies within the average of s observations $\pm \frac{2T\sqrt{k'E^s}}{\sqrt{s}}$.

(106.) The preceding is the result of Laplace, with a difference of notation, as follows, arising from the necessity of simplifying the peculiar species of infinitesimals which he has employed. To compare any result with the form given in the *Théorie des Probabilités*, for k' , k'' , &c. in this work write $k' \div k$, $k'' \div k$, &c., and for E write 1.

(107.) We now proceed to consider errors without reference to sign, that is, counting them as positive in both cases; and we suppose it required to determine the sum of a certain function of the errors, αe , or to find the probability that $\alpha e_1 + \alpha e_2 + \dots + \alpha e_s$ will be contained within given limits. It is evident that the probability of this sum being exactly $(l+\mu s)\theta$ (the errors being $n\theta$, $(n-1)\theta$, $\dots$, 0 , $\dots$, $n-1\theta$, $n\theta$, since the negative errors are reckoned as positive) is the coefficient of $\alpha^{(l+\mu s)\theta}$ in

$$\left(\psi\left(\frac{0}{n}\right) \alpha^0 + 2\psi\left(\frac{1}{n}\right) \alpha^{\alpha\theta} + \dots + 2\psi\left(\frac{x}{n}\right) \alpha^{\alpha(x\theta)} + \dots + 2\psi\left(\frac{n}{n}\right) \alpha^{\alpha(n\theta)} \right)^s \dots (1).$$

If α be $\varepsilon^{\omega\sqrt{-1}}$, the series above written has for the term containing ω^s (or would have, if for $\psi\left(\frac{0}{n}\right)$ we wrote $2\psi\left(\frac{0}{n}\right)$, which makes no difference when we take the limit),

$$\pm \frac{2(\omega\sqrt{-1})^s}{2.3\dots s} \left(\psi\left(\frac{0}{n}\right) (\alpha 0)^s + \psi\left(\frac{1}{n}\right) (\alpha\theta)^s + \dots + \psi\left(\frac{n}{n}\right) (\alpha n\theta)^s \right) \dots (2),$$

in which let $\psi\left(\frac{x}{n}\right)$ be convertible into $\theta\phi\left(\frac{X}{E}\right)$ as before, so that when n increases without limit, the limit of the last factor is $\int_0^E \phi\left(\frac{X}{E}\right) (\alpha X)^s dX$. Write this Σ_s until the limits are taken. Consequently, the preceding s th power is

$$\left(2\Sigma_0 + 2\Sigma_1 \omega\sqrt{-1} - \frac{2\Sigma_2}{1.2} \omega^2 - \frac{2\Sigma_3}{1.2.3} \omega^3 \sqrt{-1} + \dots \right)^s \dots (3).$$

But in the original expression we can detect the coefficient required by multiplying by $\varepsilon^{-(l+\mu s)\theta\omega\sqrt{-1}} d\theta\omega$, and integrating from $\theta\omega = -\pi$ to $\theta\omega = +\pi$; for $\int_{-\pi}^{+\pi} \varepsilon^{x\theta\omega\sqrt{-1}} d\theta\omega$ is 0 between these limits, except only when $x=0$, in which case it is 2π . We have then for the probability in question

$$\frac{1}{2\pi} \int_{-\pi}^{+\pi} \varepsilon^{-(l+\mu s)\theta\omega\sqrt{-1}} d\theta\omega \left(\psi\left(\frac{0}{n}\right) \varepsilon^{\alpha 0 \cdot \omega\sqrt{-1}} + \dots \right)^s, \text{ or } \frac{1}{2\pi} \int_{-\pi}^{+\pi} \varepsilon^{-(l+\mu s)\theta\omega\sqrt{-1}} d\theta\omega (2\Sigma_0 + 2\Sigma_1 \omega\sqrt{-1} + \dots)^s$$

Now previously to the operation of integrating with respect to ω , comes that of diminishing θ without limit. Let θ be always $=L$, and $\mu\theta = M$; we may then represent θ by dL , and $d(\theta\omega)$ by $dL d\omega$, the rejected term being of an inferior order. But the limits of ω , which are $\pm \frac{\pi}{\theta}$, now become $\pm \infty$. Represent the limit of $2\Sigma_0$,

$$2 \int_0^E \phi\left(\frac{X}{E}\right) dX, \text{ or } 2E \int_0^1 \phi x dx \text{ by } Ek \text{ as before } (=1); \text{ and let } \alpha X = E^{\omega} \alpha_1 \left(\frac{X}{E}\right),$$

$$\text{and let } \int_0^E \phi\left(\frac{X}{E}\right) (\alpha X)^s dX, \text{ or } E^{s+1} \int_0^1 \phi x (\alpha_1 x)^s dx \text{ be } E^{s+1} K^{(s)}.$$

The probability required is $\frac{dL}{2\pi} \int_{-\infty}^{+\infty} \varepsilon^{-(L+Ms)\omega\sqrt{-1}} d\omega (1 + 2K'E^{s+1}\omega\sqrt{-1} - K''E^{2s+1}\omega^2 - \dots)^s$. If, as before, we assume ε^{-t^2} for the s th power in question, we have

$$-t^2 = s \log(1 + 2K'E^{s+1}\omega\sqrt{-1} - K''E^{2s+1}\omega^2 - \dots) = s(2K'E^{s+1}\omega\sqrt{-1} - K''E^{2s+1}\omega^2 + 2K'^2E^{2s+2}\omega^3),$$

as far as ω^2 inclusive. Substitute this for $-t^2$, and make $-Ms + 2sK'E^{s+1} = 0$, or assume $M = 2K'E^{s+1}$, which gives for the probability required

$$\frac{dL}{2\pi} \int_{-\infty}^{+\infty} \varepsilon^{-L\omega\sqrt{-1} - s(K''E^{2s+1} - 2K'^2E^{2s+2})\omega^2} d\omega = \frac{dL}{2\sqrt{\pi s(K'E^{2s+1} - 2K'^2E^{2s+2})}} \varepsilon^{-\frac{L^2}{4s(K'E^{2s+1} - 2K'^2E^{2s+2})}},$$

which gives the probability that $\Sigma \alpha e$ shall lie between $2K'E^{s+1}s + L$ and $2K'E^{s+1}s + L + dL$. This probability is

Theory of Probabilities. greatest when $L=0$; or errors being all positive, the most probable individual value of $\Sigma \alpha e$ is $2K'E^{s+1}s$. And Theory of Probabilities. we also have the following theorem: the most probable value of $\Sigma \alpha e$ for s terms is $2K'E^{s+1}s$; and the probability of a departure from this value lying between $\pm L$ is that of a single error lying between the same limits, in an observation having the specific weight $\{4s(K'E^{2s+1} - 2K'^2E^{2s+2})\}^{-1}$. And E is the greatest value of e which is

possible, K' and K'' being respectively $\int_0^1 \phi x \alpha_1 x dx$ and $\int_0^1 \phi x (\alpha_1 x)^2 dx$, where $\phi\left(\frac{X}{E}\right) dX$ is the probability of $e=X$ and $\alpha_1 x = E^{-s} \alpha(Ex)$. But in the case where E is infinite (103.), put unity for E , and make the limit of the integrals 0 and ∞ .

The probable value admits of a confirmatory explanation, as follows: in $2K'E^{s+1}$, or

$$2E^{s+1} \int_0^1 \phi x \cdot \alpha_1 x \cdot dx, \text{ or } 2 \int_0^E \phi\left(\frac{x}{E}\right) E^s \alpha_1\left(\frac{x}{E}\right) d \cdot X, \text{ or } 2 \int_0^E \phi\left(\frac{X}{E}\right) \alpha X dX,$$

we see the sum of all the values of the function, each multiplied by its probability: and s times as much is the probable sum of s such results.

The preceding may also be written thus: the probability of

$$\Sigma \alpha e \text{ lying between } 2K'E^{s+1}s \pm 2L\sqrt{s(K'E^{2s+1} - 2K'^2E^{2s+2})} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-L}^{+L} e^{-t^2} dt.$$

(108.) Let $\alpha e = e$. Then $\alpha X = E \frac{X}{E}$, or $\alpha_1 X = X$, and $\omega = 1$; whence $K' = k'$, and $K'' = k''$. The probability of the sum of s errors lying between

$$2k'E^2s \pm 2L\sqrt{s(k'E^3 - 2k'^2E^4)} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-L}^{+L} e^{-t^2} dt.$$

(109.) Let $\alpha e = e^2$. Then $\alpha X = E^2 \frac{X^2}{E^2}$, or $\alpha_1 X = X^2$ and $\omega = 2$; whence $K' = k''$, and $K'' = k'$. The probability of the sum of the squares of s errors lying between

$$2k''E^3s \pm 2L\sqrt{s(k''E^3 - 2k'^2E^4)} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-L}^{+L} e^{-t^2} dt.$$

(110.) The last two theorems give the means of determining k' and k'' experimentally with sufficient accuracy. Add a large number of errors, and also their squares, and equate the results to $2k'E^2s$ and $2k''E^3s$. We thus obtain approximately $k'E^2$ and $k''E^3$, the necessary elements for the application of the results in (105.) and (108.), which are the cases of most practical utility.

(111.) If in the preceding problem we suppose all the functions of the errors to be different, or propose to find the probability of $\alpha_1 e_1 + \alpha_2 e_2 + \dots + \alpha_s e_s$ being contained within given limits, the only alteration required in the preceding is this, that the generating function is not an s th power, or the product of s identical factors, but the product of s factors which are similar functions of α_1, α_2 , &c. Consequently the logarithm will not be s &c., but Σ &c., or for sK' we must write $K'_1 + K'_2 + \dots + K'_s$, and the same for the rest. The probable mean is derived from $-Ms + 2\Sigma(K'E^{2s+1})$, where K', E , and ω may be different in all the different functions. The transformation may then be very easily made.

(112.) We shall now take the problem, supposing the negative errors are to count as negative, and firstly when all the functions are the same. In this case, in expression (1) of (107.), instead of $2a^{s(x^2)}$, or $a^{s(x^2)} + a^{s(x^2)}$ doubled because errors of both kinds enter with positive effect, we must write $a^{s(x^2)} + a^{-s(x^2)}$, the consequence of which

in (2.) is that instead of $2\Sigma_0$ &c. we have $\Sigma_0 + \bar{\Sigma}_0$, &c. where $\bar{\Sigma}_0$, &c. have the limits $\int_{-E}^0 \phi\left(\frac{X}{E}\right) \alpha(-X) dX$,

$\int_{-E}^0 \phi\left(\frac{X}{E}\right) \{\alpha(-X)\}^2 dX$ &c., which, if positive and negative errors be equally likely, or $\phi\left(-\frac{X}{E}\right) = \phi\left(\frac{X}{E}\right)$ gives

$\int_{-E}^0 \phi\left(\frac{X}{E}\right) (\alpha X)^2 dX$ for the limit of $\bar{\Sigma}_2$, or $\int_{-E}^{+E} \phi\left(\frac{X}{E}\right) (\alpha X)^2 dX$ must be substituted for $2\Sigma_2$ in (3). If, then,

we wish to retain the final notation of (107.), we must assume

$$\text{for } z=0 \quad E \int_{-1}^{+1} \phi x dx = Ek = 1, \quad \text{for } z=1, 2, \&c. \quad \int_{-1}^{+1} \phi x (\alpha_1 x)^z dx = 2K^{(z)};$$

and the rest of the process with the result is then as before. The probable sum is $s \int_{-E}^{+E} \phi\left(\frac{X}{E}\right) \alpha X dX$, which can be confirmed as in (107.)

Next, let all the functions be different. We have then, as in (111.), to change $sK^{(s)}$ or $K^{(s)} + K^{(s)} + \dots$ into $\Sigma K^{(s)}$ or $K_1^{(s)} + K_2^{(s)} + \dots$, similarly derived from α_1, α_2 , &c.

(113.) If the limits of positive and negative error be different, and also their facilities, suppose E_1, E_2 , &c. to be the limits of positive error, and E_1, E_2 , &c. to be those of negative error. Let νn , and n' be whole numbers always proportional to $E + E$, E and E ; then (107.) expression (1) becomes the s th power of

$$\psi\left(\frac{0}{\nu}\right) a^{n^0} + \psi\left(\frac{1}{\nu}\right) a^{n^1} + \dots + \psi\left(\frac{n}{\nu}\right) a^{n^{(n^0)}} + \psi\left(\frac{0}{\nu}\right) a^{n^0} + \psi\left(\frac{-1}{\nu}\right) a^{n^{(-n^0)}} + \dots + \psi\left(\frac{-n}{\nu}\right) a^{n^{(-n^0)}},$$

which divides (2), as it there stands, by 2, and substitutes for the last factor of (2) a sum whose limit is

Theory of Pro-
babilities. $\int_{-E}^{+E} \phi\left(\frac{X}{E+E}\right) (\alpha X)^2 dX$. When $z=0$, this is $=1$, in other cases let it be $2k^{(s)}$, and the final result is that the probability of $\alpha_1 e_1 + \alpha_2 e_2 + \dots + \alpha_s e_s$, or $\Sigma \alpha e$, lying between

Theory of Pro-
babilities.

$$2\Sigma k' \pm 2L \sqrt{\Sigma k'' - 2\Sigma k'^2} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-L}^{+L} \varepsilon^{-t^2} dt.$$

Let $\alpha_1 e_1 = m_1 e_1$, $\alpha_2 e_2 = m_2 e_2$, &c., the limits of negative error being the same throughout, and also those of positive error. If, then, $\int_{-E}^{+E} \phi\left(\frac{X}{E+E}\right) \cdot X^2 dX$ be called $k_{(s)}$, for distinction between this and the $k^{(s)}$ of (103.), we have $\Sigma k' = \frac{1}{2} \Sigma m \times k$, $\Sigma k'^2 = \frac{1}{4} \Sigma m^2 \times k^2$, and $\Sigma k'' = \frac{1}{2} \Sigma m^2 \times k''$, or the probability of the preceding sum lying between

$$\Sigma m \cdot k \pm L \sqrt{2(k'' - k'^2) \Sigma m^2} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-L}^{+L} \varepsilon^{-t^2} dt. \text{ (Laplace, p. 332.)}$$

(114.) It very frequently happens *sensibly* (always, we presume, more or less) that the means of sets of observations made by two different observers will differ sensibly, and the same way for every set: that is, that the average of A's observations will always be a little greater, or always a little less, than those of B, even for the same species of phenomena, observed with the same instrument, under the same circumstances. Undoubtedly this arises from a difference of temperament in the two observers, which induces one to suppose a phenomenon actually arrived a little before it appears so to the other, or from a difference of constitution of the eyes of the two, or something which depends on the observer only. It is called the *personal equation*. We may take account of it thus: suppose that the numerical phenomenon is A, and that if the observers could be sure of avoiding casual errors, or those which are equally likely to be positive and negative, the phenomenon would be to them A and a , so that positive and negative departures from these are equally likely. Let E and $-E$, and e and $-e$, be the limits of their errors, and S and s the number of observations in a set of each observer. The probability of error in $\Sigma A - \Sigma a$, or $\Sigma A + \Sigma(-a)$, is easily found from (113.) Let Φ and ϕ be the functional symbols of the laws of error: then

$$\begin{aligned} & S \int_{-E}^{+E} \Phi\left(\frac{z}{E+E}\right) dz - s \int_{-e}^{+e} \phi\left(\frac{z}{e+e}\right) dz \text{ being } 2SK' - 2sk', \\ \text{and} & S \int_{-E}^{+E} \Phi\left(\frac{z}{E+E}\right) z^2 dz + s \int_{-e}^{+e} \phi\left(\frac{z}{e+e}\right) z^2 dz \text{ being } 2SK'' + 2sk'', \end{aligned}$$

the probability of the error of $\Sigma A - \Sigma a$ lying between

$$2SK' - 2sk' \pm 2L \sqrt{(SK'' + sk'') - 2(SK'^2 + sk'^2)} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-L}^{+L} \varepsilon^{-t^2} dt.$$

This result is expressed in a form which will allow of our immediately passing to the supposition of infinite limits of possible error. Let T be the real phenomenon, and T+P and T+p the *personal* phenomena; that is, the phenomena which the constitution of the observers would lead them to assert, using the same instrument, &c. Supposing positive and negative departures from these to be equally likely in single observations, the laws of facility may be expressed as follows:

$$\Phi\left(\frac{z}{E+E}\right) = \sqrt{\frac{C}{\pi}} \varepsilon^{-C(P-z)^2} \quad \phi\left(\frac{z}{e+e}\right) = \sqrt{\frac{c}{\pi}} \varepsilon^{-c(p-z)^2},$$

which gives

$$2K' = P \quad 2k' = p \quad 2K'' = P^2 + \frac{1}{2C} \quad 2k'' = p^2 + \frac{1}{2c};$$

and the probability of S observations of the first observer exceeding s of the second by a quantity lying between

$$SP - sp \pm L \sqrt{\frac{S}{C} + \frac{s}{c}} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-L}^{+L} \varepsilon^{-t^2} dt.$$

When the number of observations made by both observers is the same, the difference of the sums enables us to approximate to nothing but $P - p$, the advance of one upon the other. But by taking different sets of observations, a number of equations may be obtained of the form $SP - sp = \text{obs. diff.}$, from which, by the method of least squares presently to be obtained, the values of P and p may be obtained, and their probabilities.

(115.) The considerations which have been applied to the errors of observation may be applied to the observations themselves, which will amount to the use of a process similar to that of changing the origin of coordinates in geometry. Instead of supposing positive and negative departures from zero equally likely, in which the theory of errors consists, suppose positive and negative departures from A equally likely, up to $A \pm E$.

Let $\psi\left(\frac{x-A}{E}\right) dx$ represent the probability that the observation shall lie between x and $x+dx$, or the error between $x-A$ and $x+dx-A$; then the equation

Theory of
Pro-
babilities.

$$\int_p^q \psi(x-A) dx = \int_{p-A}^{q-A} \psi x dx$$

Theory of
Pro-
babilities.

immediately shows that the theory of errors may be reduced to that of *discordant observations*. Thus the case of (105.) in the theory of errors is the same as that in (108.), when we use the observations instead of the errors: since all the observations are supposed to have one sign. Thus, from the theory of errors and (105.) we learn that the probability of the error of an average of s observations lying between

$$\pm \frac{2T\sqrt{\frac{1}{2} \text{ mean square of an error}}}{\sqrt{s}} \text{ is } \frac{2}{\sqrt{\pi}} \int_0^T e^{-t^2} dt:$$

while from the theorem on discordant observations answering to that on errors in (108.), we find that the probability of the truth lying between

$$\text{Mean of obs. } \pm \frac{2T\sqrt{\frac{1}{2} \{ \text{mean sq. of an obs.} - (\text{mean of obs.})^2 \}}}{\sqrt{s}} \text{ is } \frac{2}{\sqrt{\pi}} \int_0^T e^{-t^2} dt.$$

Let V be the mean of the observations, and $e_1, e_2, \&c.$ the errors; then

$$\frac{\sum (V+e)^2}{s} - \left\{ \frac{\sum (V+e)}{s} \right\}^2 = \frac{\sum e^2}{s} - \left(\frac{\sum e}{s} \right)^2, \text{ and } \sum e = 0.$$

Whence

$$\text{mean sq. of obs.} - (\text{mean of obs.})^2 = \text{mean sq. of error},$$

which shows the coincidence of the two methods.

(116.) If in (115.) we take that value of T which gives an even chance for the probability in question, or, (100.) $T = .4769360$, we have the following theorems, which may easily be applied without any knowledge, except that of common arithmetic, by any one who desires to know the relative merit of any sets of observations.

To determine the probable error of the mean of any sets of observations, take either of the two following methods, whichever is most convenient.

Find the mean of all the observations.

Take the excess or defect of each observation from the mean of the whole, and add together the squares of all these *reputed errors*.

Divide the square root of this sum by the number of observations, and multiply the quotient by .67449, whose logarithm is .8289751 - 1.

Find the mean of all the observations, and square it.

Square all the observed numbers, and find the mean of these squares.

From the mean square subtract the square of the mean; divide the difference by the number of observations, and multiply the square root of the quotient by .67449, whose logarithm is .8289751 - 1.

If the result of the preceding be e , it is an even chance that the error of the mean is less than e ; or as follows:

1	e	4	$1.91 e$	7	$2.27 e$	10	$2.51 e$	100	$3.80 e$
2	$1.44 e$	5	$2.05 e$	8	$2.36 e$	20	$2.93 e$	200	$4.20 e$
3	$1.71 e$	6	$2.17 e$	9	$2.44 e$	30	$3.18 e$	300	$4.90 e$

This Table signifies that it is 1 to 1 against the error of the mean exceeding e as found above; 2 to 1 against its exceeding 1.44 times as much, &c., &c., and 300 to 1 against its being 4.90 times as much.

EXAMPLE. Observed readings of the microscopes A, B, &c. of the mural circle during two observations (direct and by reflexion) of a star, the microscopes being supposed correctly placed.

	A	B	C	D	E	F
Reflected	$61''.9$	$60''.3$	$64''.3$	$58''.3$	$64''.3$	$55''.0$
Direct	31.8	23.8	29.1	24.0	27.3	24.3

which of these two observations must be considered the best?

The mean of the first readings is 60.7 , and the errors are $1.2, -4, 3.6, -2.4, 3.6$, and -5.7 , the sum of the squares of which is 65.77 . The mean of the second readings is 26.7 , and the errors are $5.1, -2.9, 2.4, -2.7, .6$, and -2.4 , the sum of the squares of which is 53.59 . The square roots of 65.77 and 53.59 are 8.11 and 7.32 , the sixth parts of which are 1.35 and 1.22 , and seven-tenths, (which is near enough for our purpose) of these results give .95 and .85. So far, then, as this one comparison can justify the formation of any opinion, the direct observation is a little better than the reflected one, and it is more than an even chance against either being wrong by so much as one second.

(117.) The Tables at the end are intended to facilitate the determination of all probabilities depending on $\int e^{-t^2} dt$. When we began to write this Article, we were not in possession of any other Table of the integral except that given by Kramp, in his *Analyse des Réfractions*, Strasburg, 1799. We afterwards found the article on the method of least squares in the Berlin *Astronomisches Jahrbuch* for 1834, appended to which are Tables in a more convenient form for this specific subject. But considering the great and increasing importance of the integral $\int e^{-t^2} dt$, and the difficulty of obtaining Kramp's work in this country, we have considered it advisable to insert the Tables from both works.

Theory of
Pro-
babilities.

Tables I. and II. (which run together) contain the values of the integral from t to infinity, together with the logarithms of the values, and the differences of both, and are taken from Kramp. They have already been used (74.), and need no further explanation. They were calculated (Kramp, p. 135.) from the following approximate formula, ($\Delta t = r = .01$), obtained from Taylor's theorem,

Theory of
Pro-
babilities.

$$\Delta \int_t^\infty e^{-t^2} dt = -r e^{-t^2} \left(1 - rt + \frac{2t^2 - 1}{3} r^2 - \frac{2t^3 - 3t}{6} r^3 \right).$$

(118.) Table III. contains the values of the integral from *nothing* to the values of t which appear as arguments, multiplied by $2 \div \sqrt{\pi}$, thus giving the values of the function at which we have so frequently arrived. It is from the *Jahrbuch* cited above, but we do not know whether it depends on the Table of Kramp, or was calculated independently.

(119.) Table IV. (from the same work) contains the integral of Table III., the limits being, not t the argument, but $.4769360 \times t$, so that it gives by inspection the probability of the error being within $t \times e$, in which e is the probable error, or error which there is an even chance of not exceeding. The following is an example of its use.

If the odds for success in a single trial be as 7 to 3, required the probability that, out of 1000 trials, the successes shall lie between $700 \pm a$. We ascertain first the value of a , for which there is an even chance. This (74.) must be found by equating $a \sqrt{1000 \div 2 \times 700 \times 300}$ to $.476936$, which gives $a = 10$ (in round numbers), or it is about an even chance that out of 1000 trials the successes lie between 690 and 710. Looking in Table IV., opposite to 2, we find .82: that is, it is 82 to 18, or more than 4 to 1, that the successes lie between $700 \pm 2 \times 10$, or between 680 and 740.

(120.) Table V. is abridged from C. F. Degen, *Tabularum ad faciliorem et breviorum probabilitatis computationem utilium Enneas*, Copenhagen, 1824. It contains the logarithms of the values of $1.2.3 \dots x$, or $[x]$, as we have called it, from $x=1$ to $x=1200$; and its utility is sufficiently apparent.

(121.) The method of correction known by the name of that of *least squares* is comparatively of recent date. It was proposed by Legendre* in 1806, not as having any foundation in the Theory of Probabilities, but as a very convenient method of reducing equations which are more in number than the unknown quantities to a set which, while they give only one result, will make that result partake of the peculiarities of all the equations in question.

If, for instance, a , b , and c be variable elements which are connected together by the equation $ax + by = c$, where x and y are constant, but unknown, it is plain that two correct simultaneous observations of a , b , and c will accurately determine x and y . But suppose twenty sets of observations to be made, affected with errors, it is equally clear that the use of different pairs of observations will give different values of x and y ; so that 190 different results might be obtained, the average of which, it might be supposed, would give values very near the truth. But if the results of observation be $a_1, b_1, c_1; a_2, b_2, c_2$, &c.; and if α_n, β_n , and γ_n be the errors of the n th observations, it is plain that $a_n x + b_n y - c_n$, instead of being 0, as it should be, will be $\alpha_n x + \beta_n y - \gamma_n$, if x and y have their true values. Let this be called e_n ; we have then sets of equations of the form $a_n x + b_n y - c_n = e_n$, where a_n, b_n, c_n are observed, e_n is unknown but small, and as likely to be positive as negative; and the question is, to determine the most probable values of x and y . The most probable value of the sum of the errors is 0, and $\sum e_n = 0$ gives $x \sum a_n + y \sum b_n - \sum c_n = 0$, an equation of a high degree of probability as compared with any of the components from which it is formed, but still only one, whereas two are wanted to determine x and y . If we take the equations

$$x + \frac{b_n}{a_n} y - \frac{c_n}{a_n} = \frac{e_n}{a_n}, \quad \frac{a_n}{b_n} x + y - \frac{c_n}{b_n} = \frac{e_n}{b_n}, \quad \text{and assume } \sum \frac{e_n}{a_n} = 0, \quad \sum \frac{e_n}{b_n} = 0,$$

we have (s being the whole number of observations)

$$sx + \sum \frac{b}{a} \cdot y - \sum \frac{c}{a} = 0, \quad \sum \frac{a}{b} \cdot x + sy - \sum \frac{c}{b} = 0,$$

which are two equations of higher probability than any of the originals, and from which values of x and y may be obtained. But the hypothesis on which we here proceed is pure assumption; and we are not to be content with two equations simply more probable than any of those derived from single observations; but must endeavour to find those which are more probable than any others whatsoever.

(122.) Legendre observed, that by giving x and y those values which make $\sum e^2$ the least possible, 1. as many equations are obtained as there are unknown quantities, and no more; 2. the method reduces itself in several remarkably simple cases to that which the unassisted judgment most approves. For 1. The rules of the differential calculus give $\sum (ax + by - c)^2$ a *minimum*, when $\sum a^2 \cdot x + \sum ab \cdot y - \sum ac = 0$ and $\sum abx + \sum b^2 \cdot y - \sum bc = 0$; and 2. when $x=a$ is the equation, and observation of a is to determine x , then $\sum (x-a)^2$ a *minimum* gives $x =$ the average of a_1, a_2 , &c. And Legendre also observed, that an old proposition relative to the position of the centre of gravity of a number of points in space is a theorem of this method. If equal weights be applied at each point,

* *Nouvelles méthodes pour la détermination des orbites des comètes*, Paris, 1806. La méthode qui me paroît la plus simple et la plus générale, consiste à rendre minimum la somme des quarrés des erreurs. On obtient ainsi autant d'équations qu'il y a des coefficients inconnus, &c. Preface.

Par ce moyen, il s'établit entre les erreurs une sorte d'équilibre qui empêchant les extrêmes de prévaloir, est très propre à faire connaître l'état du système le plus proche de la vérité. Appendix.

It must be stated, however, that Gauss, in the *Theoria Motus Corporum*, &c. Hamburg, 1809, mentions his having used the same method from the year 1795. *Ceterum principium nostrum, quo jam inde ab Anno 1795, usi sumus, nuper etiam a clar. Legendre in opere Nouvelles Méthodes, &c., prolutum est, &c.*—p. 221.

Theory of
Pro-
babilities.

the centre of gravity is a point so placed, that the sum of the squares of its distances from all the points is a minimum; that is, a_n, b_n , and c_n being the n th observation of the coordinates, the choice of the centre of gravity as the most probable mean of all the observed points is the assumption of those values of x, y and z , which make $\Sigma(x-a)^2 + \Sigma(y-b)^2 + \Sigma(z-c)^2$ a minimum. Circumstances of this kind brought the method into use as one which had as fair claims as any other, and could not be far wrong, at least if any whatever could be right.

Theory of
Pro-
babilities.

(123.) The method of least squares was shown by Laplace to give the most probable, as well as the most convenient result. As a demonstration has not, to the best of our knowledge, found its way into any elementary work, we shall confine ourselves, in the first instance, to the most simple case, $ax=b$, where a and b are to be determined by observation, and s sets of observations have been made. We have as well to establish the method itself as to meet the objections which have been taken to it. These, for the most part, seem to resolve themselves into a supposition, that the formation of an average is a method of which the soundness is almost self-evident and universally admitted, while the method of least squares has a hard and mathematical name, and is a deduction from dubious principles. With regard to the soundness of the average, we have shown (89.) that, in an absolute sense, it is derived from a pure notion of the mind, independent of the individual qualities of the observations; and that it is by no means a necessary truth, being only admissible as such when one particular law of the facility of errors exists. Consequently, when we only know the observations themselves, and have nothing to guide us as to the law of facility, if we assume the average, we assume with it the law of facility in question. We leave out of view the subsequent demonstration, that whatever the law of facility may be, the most probable result of a considerable number of observations cannot differ sensibly from the average, because that consideration, rendering the probable truth of the average itself a matter of deduction as complicated as the method of least squares, cannot be a ground of objection against the latter as compared with the former.

(124.) There are two obvious ways in which the average equation of $a_1x=b_1, a_2x=b_2$, &c. may be formed: the first by averaging a and b separately for the probable values, and then solving the equation; the second by forming the solutions first, and then averaging. We leave to the objectors the decision between these two methods, as to which is the one which unassisted judgment would point out.

The first gives $x = \frac{\Sigma b}{\Sigma a}$; the second gives $x = \frac{1}{s} \Sigma \left(\frac{b}{a} \right)$. Both are particular cases of the following, in which we shall consider them. Let the equations have been previously multiplied by $m_1 m_2 \dots m_s$, so that the solution of the average equation $\Sigma ma.x = \Sigma mb$ is $x = \frac{\Sigma mb}{\Sigma ma}$, the risk of which is (supposing a and b to have equal risks)

$$\sqrt{\frac{\Sigma m^2}{(\Sigma ma)^2} + \frac{\Sigma m^2 (\Sigma mb)^2}{(\Sigma ma)^4}} \rho a, \text{ or } \sqrt{1 + \left(\frac{\Sigma mb}{\Sigma ma} \right)^2} \cdot \frac{\sqrt{\Sigma m^2}}{\Sigma ma} \cdot \rho a.$$

The second average, of which the result was given above, is a particular case of this, derived from $m_1 = \frac{1}{a_1}$, &c.; the first supposes $m_1 = m_2$, &c. = 1. It remains to determine m_1, m_2 , &c. in such a way that the preceding risk may be the least possible.

Now $\Sigma mb \div \Sigma ma$ must lie between the extreme values of $b \div a$, and therefore the factor in which it appears only differs from the truth by a quantity of the order of the squares of the errors, and may be considered as constant. The remaining factor is therefore to be made a minimum. The differentiation of $\Sigma m^2 \div (\Sigma ma)^2$ with respect to m_1 gives, when the result is equated to zero, $2m_1 \cdot (\Sigma ma) - 2a_1 \Sigma m^2 = 0$, whence

$$\frac{m_1}{a_1} = \frac{m_2}{a_2} = \frac{m_3}{a_3} = \dots = \frac{\Sigma m^2}{\Sigma ma}$$

expresses all the requisite conditions, and m_1, m_2 , &c. are proportional to a_1, a_2 , &c. This gives for the final result $\Sigma ab \div \Sigma a^2$, which is the value of x necessary to make $\Sigma (ax-b)^2$ a minimum. The result is the same as arises from assuming $m_1 = a_1, m_2 = a_2$, &c., and the mean risk of error is therefore (x being the obtained result)

$$\frac{\text{risk of a single observation}}{\sqrt{1+x^2} \sqrt{\Sigma a^2}},$$

on which we have to observe, that when x is very small, $\rho a \div \Sigma a^2$ expresses the absolute value of the risk; but that when x is considerable, the same fraction expresses the proportion of the error to the whole result: whence it is always best, if possible, to observe the coefficients of equations which give small results. This is made still more desirable by observing that, *cæteris paribus*, the greater the value of a , the smaller the risk of error.

(125.) The preceding is entirely based upon the supposition, that the risk of a single error being between e and $e+de$ is $\sqrt{c \div \pi} \varepsilon - e^2 de$, to which, as we have seen, every admissible law approximates (and we may add, with a closeness unknown in most other approximations) for a moderately great number of observations. The result of Laplace (p. 320, changing the notation) is $E \sqrt{k'' \div k \pi} \div \sqrt{\Sigma a^2}$, in which (103.) $E=1$, as the limits of possible errors are infinite, and Ek is also $=1$, whence $k=1$. But, in Laplace, the expressions k'' and k have reference to $ax-b$, considered as a single result; whence if c be the specific weight of that result, we have $k'' = \int_0^\infty \phi e \cdot e^2 de$, which, if ϕe be $\sqrt{c \div \pi} \varepsilon - ce^2$, is $1 \div 4c$. Hence $\sqrt{k'' \div \pi}$ is $1 \div 2 \sqrt{c \pi}$, the mean risk of $ax-b$. But, the mean risks of a and b being the same, that of $ax-b$ is (98.) $\sqrt{(\rho a)^2 x^2 + (\rho b)^2}$, or $\sqrt{1+x^2} \times$ mean risk of a or b ; whence the accordance of the two results* is manifest.

* This proof of the method of least squares appears very much more simple than that of Laplace, which is owing to our not

Theory of
Pro-
babilities.

(126.) The preceding also specifically depends upon the supposition, that the weights of all the observations are equal: and we have sometimes seen the method of least squares, in the most usual meaning of the words, applied to cases in which the different a s and b s were themselves means of different numbers of observations, and therefore not equally good. Let us now suppose every a and every b to be an observation with a distinct specific weight. Hence the risk of the average $\Sigma mb \div \Sigma ma$ is

Theory of
Pro-
babilities.

$$\sqrt{\frac{\Sigma(m\rho b)^2}{(\Sigma ma)^2} + \frac{\Sigma(m\rho a)^2 (\Sigma mb)^2}{(\Sigma ma)^4}}, \text{ or } \sqrt{\frac{\Sigma(m\rho b)^2 + x^2 \Sigma(m\rho a)^2}{(\Sigma ma)^2}},$$

x being $\Sigma mb \div \Sigma ma$, the presumed value, and $\rho a_1, \rho b_1$, &c. the mean risks of a_1, b_1 , &c. Differentiate with respect to m_1 , and we have

$$\frac{m_1}{a_1} \{(\rho b_1)^2 + x^2 (\rho a_1)^2\} = \frac{\Sigma(m\rho b)^2 + x^2 \Sigma(m\rho a)^2}{\Sigma(ma)}, \text{ and so on;}$$

this is satisfied by $m_1 = a_1 \div \{(\rho b_1)^2 + x^2 (\rho a_1)^2\}$, &c. &c.: that is, the probable mean is the value of x which makes $\Sigma \frac{(ax-b)^2}{(\rho b)^2 + x^2 (\rho a)^2}$ a minimum, where x_1 is a near approximation; and the mean risk of error of this result is the reciprocal of the square root of $\Sigma \left(\frac{a^2}{(\rho b)^2 + x_1^2 (\rho a)^2} \right)$, which, as should be, agrees with the result in (124.), when $\rho a_1 = \rho a_2 = \rho b_1 = \&c.$

(127.) Since the mean risks are inversely as the square roots of the specific weights, let α_1, α_2 , &c. be the specific weights of a_1, a_2 , &c., and β_1, β_2 , &c. those of b_1, b_2 , &c. Then the most probable result of $a_1 x = b_1$, &c. is that value which makes the first of the following expressions a minimum; and its mean risk is the second:

$$\Sigma \frac{\alpha\beta}{\alpha + \beta x_1^2} (ax-b)^2: \quad \sqrt{1 \text{ divided by } \Sigma \frac{\alpha\beta a^2}{\alpha + \beta x_1^2}}.$$

The expression $ax-b$, considered independently, has the risk $\sqrt{x^2 (\rho a)^2 + (\rho b)^2}$, whence a case of the following remarkable theorem, which is true of all functions whatsoever.

Let $U_1=0, U_2=0$, &c. be equations which give nearly the same value of x , and which should give exactly the same, if certain data of observation could be made absolutely correct. Let c_1, c_2 , &c. be the specific weights of U_1, U_2 , &c., determined from (mean risk) $\times \sqrt{\text{specific weight}} = 1 \div 2\sqrt{\pi}$. Then the most probable value of x is that which makes $\Sigma c U^2$ a minimum. The mean risk of this result is the reciprocal square root of $\Sigma 4\pi c \left(\frac{dU}{dx} \right)^2$, or its

specific weight is $\Sigma c \left(\frac{dU}{dx} \right)^2$. The generalization is easily made by the process in (98.): the correction of x (which call ξ) being reducible to the solution of an equation of the form $m\xi + n = 0$, where m and n are to be observed.

(128.) In the preceding process it is to be remarked, that it is not necessary for a and b to be derived from observations of the same phenomena; it is sufficient that they give nearly the same values of x . The point of difficulty is the determination of the relative weights. So long as we really appeal to independent observations of the same a and b , made under the same circumstances, the most simple case of the formula may be applied. But if, as frequently happens, the coefficients a and b are under different circumstances, it must be remembered that the making of ΣU^2 a minimum, or tacitly supposing an equal weight throughout the observations, does not give a result which is necessarily better than an ordinary average, except when the weights are nearly equal.

This point can be best tested by approximating to $k''E^3$, or $1 \div 4c$, remembering that $2k''E^3$ s, or in this case $2k''$ s, since the possible limits are infinite, that is, $s \div 2c$, will be nearly equal to the sum of the squares of a large number of errors. Or the specific weight of a single observation may be assumed at half the reciprocal of the average square of an error. Nor will this result be sensibly affected if we take reputed errors derived from the mean, as in (116.). Thus, if the average square of 20 errors give .01, the specific weight is about 50. This rough test may be generally applied with great ease; and it would be highly advisable in series of observations to examine the sums of the squares of the errors for each day's work: from which we are persuaded a much better notion might be formed of the relative value of the different sets, than from the unassisted estimation of the observer. It is very well known, that nothing is more common than for an observer entirely to mistake the relative merits of his individual observations; we know of nothing to show that any one is a better judge by estimation of a collective set, than of the individual cases composing it. The application of the preceding test would either afford to every person an irresistible confirmation of his own judgment, or would gradually lead him to better habits of estimation.

(129.) Applying the results of the last article to (124.), and making $ax-b=e$, when x has its real value, and a and b are observed (in which case all e is error), we find $\rho e \div \sqrt{\Sigma a^2}$ for the mean risk of the most probable result.

virtually repeating the process in (98.), as is done by our illustrious guide, not once or twice, but always. The fact is, that the greater part of the *Théorie des Probabilités* is a reprint of papers in the *Memoirs of the Academy*, which appear to contain the contents of the first papers on which he set down his processes. These, with preliminary chapters, descriptive, not of what follows, but of the general methods which he drew from the following parts, make up the whole work.

Theory of Pro-
babilities. But the specific weight of e is $s \div 2\Sigma e^2$ very nearly, where s is the number of equations. Substitute for pe its value $1 \div 2\sqrt{\text{sp. w.} \times \pi}$, which gives $(x = \Sigma ab \div \Sigma a^2)$, Theory of Pro-
babilities.

$$\frac{pe}{\sqrt{\Sigma a^2}} = \sqrt{\frac{\Sigma(ax-b)^2}{2s\pi \Sigma a^2}} = \sqrt{\frac{\Sigma(a \cdot \Sigma ab - b \Sigma a^2)^2}{2s\pi (\Sigma a^2)^3}} = \frac{\sqrt{\Sigma a^2 \Sigma b^2 - (\Sigma ab)^2}}{\Sigma a^2 \sqrt{2s\pi}};$$

since $\Sigma(a^2(\Sigma ab)^2) = \Sigma a^2 \times (\Sigma ab)^2$, &c. We have thus an approximate value of the mean risk in terms of the data of observation only.

(130.) Now let there be any number, l , of unknown quantities, $x, x', x'',$ &c. to be determined from a set of s equations ($s > l$) of the form

$$a_1x + a'_1x' + a''_1x'' + \dots = h_1, \text{ or } u_1 = 0 \\ a_2x + a'_2x' + a''_2x'' + \dots = h_2, \text{ or } u_2 = 0, \text{ \&c.,}$$

where $a, a', \dots, h$ are data of observation. If we were to multiply these equations by $m_1, m_2,$ &c., $n_1, n_2,$ &c., and thus form l equations $\Sigma m a_1 x + \dots = \Sigma m h_1$, $\Sigma n a_1 x + \dots = \Sigma n h_1$, and then deduce the mean risk of $x, x', \dots$ derived from these equations, we should find that risk to be a minimum when $m_1 = a_1, m_2 = a_2,$ &c., $n_1 = a'_1, n_2 = a'_2,$ &c., or when $x, x', \dots$ have the values which make Σu^2 a minimum. We might thus extend the process of (124.) and (126.), which we should recommend the student to do in the case of $l=2$. Instead of this, suppose it granted that the method of least squares is true up to $l-1$ quantities. It is obvious that the most probable values of $x', x'', \dots$ must also be their most probable values derived from any set of equations which are mathematically equivalent to the preceding.

LEMMA. If $u, u', u'', \dots$ be severally functions of $x, y, z, \dots$, and if the value of x derived from $u=0$, be substituted throughout $\phi(u, u', u'', \dots)$, called also $\alpha(x, y, z, \dots)$, thereby making it become $\beta(y, z, \dots)$: the values of $y, z, \dots$, which make β a minimum, are also those which, with the proper value of x , make α a minimum. Let $d\phi = Adu + A'du' + \dots$, $du = m dx + n dy + p dz + \dots$, $du' = m' dx + n' dy + p' dz + \dots$; then the values of $y, z, \dots$, which make β a minimum, are those determined from $u=0, du=0, A'du' + A''du'' + \dots = 0$, for all ratios of $dy, dz, \dots$. From this we find

$$A' \left(n' - m' \frac{n}{m} \right) + A'' \left(n'' - m'' \frac{n}{m} \right) + \dots = 0 \quad A' \left(p' - m' \frac{p}{m} \right) + \dots = 0, \text{ \&c. \&c.,}$$

$$\text{or} \quad An + A'n' + \dots - \frac{n}{m} (Am + A'm' + \dots) = 0, \text{ or } \Sigma An = \frac{n}{m} \Sigma Am, \quad \Sigma Ap = \frac{p}{m} \Sigma Am, \text{ \&c.}$$

If, then, to the system of equations which makes β a minimum, we add $\Sigma Am = 0$, we have $\Sigma Am = 0, \Sigma An = 0, \Sigma Ap = 0$, &c., which are the conditions under which α is a minimum.

This lemma contains almost obviously the means of showing the truth of the method of least squares as to l equations from its truth as to $l-1$ equations. Assuming $u_1 = 0$, eliminate x out of $u_2 = 0$, &c. We thus get $l-1$ equations, containing $x', x'', \dots$, of which we presume the most probable values are those which make $u_2^2 + u_3^2 + \dots$ a minimum, after x is eliminated. But these values are those which make Σu^2 a minimum with regard to $x', x'', \dots$. Assuming, therefore, these values, we have now only to ask what value of x is the most probable result of $u_1 = 0$, &c., after these most probable values of $x',$ &c. have been substituted. The answer is, that value (124.), which makes Σu^2 a minimum with respect to x alone; the condition of which, combined with the other conditions, shows that the most probable set of values of the whole l quantities is derived from the same method as that of the $l-1$.

(131.) We now pass to the case of the last article, with this addition, that $a_1, a_2,$ &c., $a'_1, a'_2,$ &c., $h_1, h_2,$ &c. all have different risks. Looking at the last process, we see that it enables us to assert our proposition with respect to l quantities by means of $l-1$ quantities, to every extent to which it can be asserted of the latter. In (124.), it is shown, that in the case of one unknown quantity, the condition $d \cdot \Sigma u^2 = 0$ gives the true result, not only in the case where $a_1, a_2,$ &c., $b_1, b_2,$ &c. have all the same risks, but also when they have different risks, provided only that $x^2(\rho a)^2 + (\rho b)^2$ be the same in all the equations. That is, our result is true, if $u_1, u_2,$ &c. all have the same risk, in whatever manner the component risks may differ. Again, k being a determined constant, the risk of kz is $k\rho z$. Divide, then, the equations $u_1 = 0, u_2 = 0,$ &c. by such quantities as will make their risks equal; that is, k being arbitrary, divide by $k\rho u_1, k\rho u_2,$ &c. If we were to divide by $\rho u_1, \rho u_2,$ &c. we should reduce the risks to unity, which may appear not to be a small risk: but the risks are now all equal to $1 \div k$, which may be made as small as we please. Consequently, the theorem in the last article applies to $u_1 \div k\rho u_1$, in place of u_1 , &c., and the most probable result is derived from making $\Sigma (u^2 \div k^2 (\rho u)^2)$, or $\Sigma (u^2 \div (\rho u)^2)$ a minimum. This answers to the generalization in (126.), which might have been established in the same way.

(132.) It remains to inquire, what is the mean risk of the result thus obtained? First, let the risks of all the expressions $u_1, u_2,$ &c. be the same; let $x, x',$ &c. be the probable values of the unknown quantities. Then we must have the following equations, deduced from the equations which the method of least squares gives.

$$\Sigma a^2 x + \Sigma a a' x' + \dots = \Sigma a h, \quad \Sigma a a' x + \Sigma a'^2 x' + \dots = \Sigma a' h, \text{ \&c. \&c.}$$

Now, in virtue of the risks of $a_1, a_2,$ &c., $a'_1, a'_2,$ &c., let e_1 be the error of u_1 , &c., so that $u_1 = e_1, u_2 = e_2,$ &c. would give the true results, taking $a_1, a_2, \dots, h_1, h_2, \dots$, as they have been observed. Let $\xi, \xi',$ &c. be the corrections of $x, x',$ &c., in consequence of these total errors: then we have

$$\Sigma a^2 \xi + \Sigma a a' \xi' + \dots = \Sigma a e, \quad \Sigma a a' \xi + \Sigma a'^2 \xi' + \dots = \Sigma a' e, \text{ \&c. \&c.}$$

From which it follows, that changing $h_1, h_2,$ &c. into $e_1, e_2,$ &c., the values of $x, x',$ &c. become those of $\xi, \xi',$ &c. And they assume the form

Theory of
Pro-
babilities.Theory of
Pro-
babilities.

where $M, A, A', \&c.$ are easily (in principle) obtained from the solution of the linear equations. Now, in calculating the risks of $\xi, \xi', \&c.$, it is unnecessary to consider those of $a, a', \&c.$, both because the risks of these quantities are already considered in $e_1, e_2, \&c.$; and because, were it not so, $e_1, e_2, \&c.$ being already of the order of the errors, the errors of $a_1, a_2, \&c.$ would only enter in terms of the second order. Consequently the risks of $e_1, e_2, \&c.$ being the same (let each be ρe), we have for the several mean risks

$$\rho\xi = \rho x = \frac{\rho e}{M} \sqrt{(Aa_1 + A'a'_1 + \dots)^2 + (Aa_2 + A'a'_2 + \dots)^2 + \dots},$$

$$\rho\xi' = \rho x' = \frac{\rho e}{M} \sqrt{(Ba_1 + B'a'_1 + \dots)^2 + (Ba_2 + B'a'_2 + \dots)^2 + \dots}$$

where the expressions under the radical signs are $A^2 \Sigma a^2 + A'^2 \Sigma a'^2 + \dots + 2AA' \Sigma aa' + \dots$, and so on.

(133.) To apply this to the case of two quantities, observe that $a_1 x + a'_1 x' = h_1$, &c. give $\Sigma a^2 \cdot x + \Sigma aa' \cdot x' = \Sigma ah$ and $\Sigma aa' \cdot x + \Sigma a'^2 \cdot x' = \Sigma a'h$, from which we deduce

$$x = \frac{\Sigma a'^2 \cdot \Sigma ah - \Sigma aa' \cdot \Sigma a'h}{\Sigma a^2 \cdot \Sigma a'^2 - (\Sigma aa')^2} \quad x' = \frac{\Sigma a^2 \cdot \Sigma a'h - \Sigma aa' \cdot \Sigma ah}{\Sigma a^2 \cdot \Sigma a'^2 - (\Sigma aa')^2}$$

$$M = \Sigma a^2 \cdot \Sigma a'^2 - (\Sigma aa')^2, \quad A = \Sigma a'^2, \quad A' = -\Sigma aa', \quad B = -\Sigma aa', \quad B' = \Sigma a^2,$$

$$\rho x = \frac{\rho e \sqrt{\Sigma a'^2}}{\sqrt{\Sigma a^2 \cdot \Sigma a'^2 - (\Sigma aa')^2}} \quad \rho x' = \frac{\rho e \sqrt{\Sigma a^2}}{\sqrt{\Sigma a^2 \cdot \Sigma a'^2 - (\Sigma aa')^2}}$$

For ρe write its probable value $\sqrt{\Sigma e^2 \div 2s\pi}$, derived as in (128.), and we have the expressions of Laplace.

(134.) There are several equations of connection between $A, A', \&c.$, $B, B', \&c.$, which it would be worth while to investigate only if (which never happens) more than three or four unknown quantities are considered together. For instance, the quantities under the radical sign in the results of (132.) all contain M as a factor. But the following is the only property which will be of use here, as by it we pass from the risk in the case of $l-1$ to that in the case of l quantities. Suppose we eliminate one of the variables (t , whose coefficients in $u_1, u_2, \&c.$ are $\theta, \theta', \&c.$) from the s equations in (130.) We have then a set of $s-1$ equations of the following form:

$$\left\{ \Sigma a^2 - \frac{(\Sigma a\theta)^2}{\Sigma \theta^2} \right\} x + \left\{ \Sigma aa' - \frac{\Sigma a\theta \cdot \Sigma a'\theta}{\Sigma \theta^2} \right\} x' + \dots = \Sigma ah - \frac{\Sigma a\theta \cdot \Sigma h\theta}{\Sigma \theta^2};$$

and so on; using the equation in which t has the coefficient $\Sigma \theta^2$, as the eliminator. And since the value of x , and its risk, so far as the same depends upon forms derived from the solution, will be the same from whichever set it is derived, we may ascertain the successive risks of two, three, &c. unknown quantities, by changing Σz^2 into

$\Sigma z^2 - \frac{(\Sigma z\theta)^2}{\Sigma \theta^2}$, and $\Sigma zz'$ into $\Sigma zz' - \frac{\Sigma z\theta \cdot \Sigma z'\theta}{\Sigma \theta^2}$; where Σ after the change contains one more term than before, as

does Σe^2 in the coefficient. Thus, having $\sqrt{1 \div \Sigma a^2}$ for the coefficient of ρe in the case of one unknown quantity, we immediately obtain

$$\sqrt{1 \div \left(\Sigma a^2 - \frac{(\Sigma aa')^2}{\Sigma a'^2} \right)}, \text{ or } \sqrt{\Sigma a'^2} \div \sqrt{\Sigma a^2 \cdot \Sigma a'^2 - (\Sigma aa')^2}$$

for two unknown quantities, and

$$\left(\Sigma a'^2 - \frac{(\Sigma a'a'')^2}{\Sigma a''^2} \right) \div \sqrt{\left\{ \Sigma a^2 - \frac{(\Sigma aa')^2}{\Sigma a'^2} \right\} \left\{ \Sigma a'^2 - \frac{(\Sigma a'a'')^2}{\Sigma a''^2} \right\} - \left\{ \Sigma aa' - \frac{\Sigma aa'' \Sigma a'a''}{\Sigma a''^2} \right\}^2},$$

or $\sqrt{\Sigma a'^2 \cdot \Sigma a''^2 - (\Sigma a'a'')^2} \div \sqrt{\Sigma a^2 \cdot \Sigma a'^2 \Sigma a''^2 + 2\Sigma aa' \Sigma a'a'' \Sigma a''a - \Sigma a^2 \cdot (\Sigma a'a'')^2 - \Sigma a'^2 (\Sigma a''a) - \Sigma a''^2 (\Sigma aa')^2}$,

for three unknown quantities, and so on. To extend the same process to equations of different weights, divide each coefficient by the square of the risk of its equation.

(135.) Upon reviewing the whole process of the method of least squares, it seems to us, 1. That this method is at least as worthy of confidence as the notion that the average of observations of a single phenomenon gives the most probable result. 2. That its weak point in practice is the difficulty of ascertaining with great precision the weights to be given to the several equations. With regard to the latter point, it may be shown that errors in the estimation of mean risks must be considerable before they can much affect the mean risk of the result.

Let $\lambda_1, \lambda_2, \&c.$ be the presumed multipliers of $a_1 x - b_1, a_2 x - b_2, \&c.$ as in (131.), which are to reduce the equations in (124.) to equations of equal risk; derived from the general form $\lambda = 1 \div \sqrt{x^2 (\rho a)^2 + (\rho b)^2}$. We may then consider $\lambda a x - \lambda b = 0$ as giving a new set of equations in which the coefficients λa and λb are affected both by the error of observation and that of estimation. If we could determine $\rho \lambda$, the risk of the preceding expression might then be ascertained from

$$\lambda^2 \{ (\rho a)^2 x_1^2 + (\rho b)^2 \} + (\rho \lambda)^2 (ax - b)^2, \text{ or } 1 + (\rho \lambda)^2 (ax_1 - b)^2.$$

Consequently (126.), we must make $\Sigma \left\{ \frac{\lambda^2}{1 + (ax_1 - b)^2 (\rho \lambda)^2} (ax - b)^2 \right\}$ a minimum.

Now, since it is not the absolute errors of $\lambda_1, \lambda_2, \&c.$ which affect our result, but only the errors of their proportions, and since

Theory of
Pro-
babilities.

$$(ar_1 - b)^2 (\rho\lambda)^2 = \frac{(ax_1 - b)^2}{(\rho a)^2 x_1^2 + (\rho b)^2} \cdot \left(\frac{\rho\lambda}{\lambda}\right)^2, \text{ which is of the order } \frac{1}{x_1^2} \left(\frac{\rho\lambda}{\lambda}\right)^2,$$

Theory of
Pro-
babilities.

we see that the method is abundantly secure if $\rho\lambda \div \lambda$ be of the same order as ρa , &c., and the more so the greater the value of the unknown quantity.

(136.) The methods which precede imply that we are obliged to make use of all the equations, so that if one or more should give results very different from the mean as compared with the rest, it is not therefore to be either rejected or modified. But it would not be difficult, having determined the most probable value, or even any kind of mean, to return with that value to the equations, and to select a set from which, if a new probable value were deduced, its risk with reference to its own equations, or even to all the equations, should be less than the most probable value of all. This Laplace has done in a method on which he lays some stress, having explained it in three places.* He calls it the *method of situation*, and still continuing to style that of least squares the *most advantageous*, we accordingly find conditions under which it is stated in so many words, that the method of situation is *better* than the *most advantageous* method. But it must be remembered that Laplace did not speedily come to the consideration of a method of least squares *with equations of different weights*; which appears for the first time in the third supplement. His method, properly considered, is only one of the infinite number of ways in which presumptions drawn from the most probable result might be allowed to affect the presumed weights of the equations: and we cannot discover any reason why his particular method should be preferred. At the same time we cannot refuse to allow that the establishment of a most probable result places us in the circumstances alluded to in (15.), where we have to return upon the premises with new probabilities forced upon us by the conclusion. The probability of an equation is that of its result being exactly true: consequently, X being the most probable value of x , and x_n that derived from the n th equation, the reputed probability of that equation is as $\varepsilon^{-c(X-x_n)^2}$, where c is the specific weight of the result, derived from the mean risks. When we have more than one unknown quantity, we may either ascertain its probability with respect to x , where x_n is the value of x deduced after substitution of the probable values of x' , x'' , &c.: or we may ascertain the joint probability of any l equations (l being the number of unknown quantities), which will be as the product of $\varepsilon^{-c(X-x)^2}$, $\varepsilon^{-c'(X'-x')^2}$, &c. The principle explained in the article CALCULUS OF FUNCTIONS, § 37, furnishes a method by which the method of successive substitution may be appended to that of least squares. Assuming the weights as nearly as they can be found, ascertain the most probable result, from which find the weights of the equations. If these agree with the assumed weights, the process is finished: if not, repeat the process with the new weights (or if we wish to give more importance to the first weights, with the mean proportionals between them and the new weights), and so on, until a result is obtained for which the assumed and deduced weights of the equations are sufficiently near to equality. This process would involve considerable labour, but the time must arrive when the method of least squares will require to be modified in this or some equivalent manner.

(137.) The method of least squares coincides with the ordinary solution when the number of equations is the same as that of unknown quantities; but when the unknown quantities are in excess, it gives an indeterminate problem, since, though as many equations as unknown quantities are produced, they are reducible to the original equations, and are not independent.

(138.) The method of least squares holds true when positive and negative errors are not equally likely: the only difference being in the specific weight of the result, and in $\sqrt{c \div \pi} \int \varepsilon^{-c^2} de$, from $+e$ to $-e$, no longer denoting the probability of an error between these limits, but between $M \pm e$, where M is the mean error obtained on considerations similar to those in (107., &c.) But it is hardly worth while to enter into detail on this point, and we therefore pass to other applications of the theory.

(139.) Dividing all discrepancies into errors of observation, and unexplained phenomena, the former of which are as likely to be positive as negative, we may immediately ascertain what, as respects two average results, is the relative probability of their difference being referable to one or the other class. Let there be two phenomena A and B , which, being at first supposed under the same circumstances, are found to differ in s observations, the sum of all the A 's exceeding that of the B 's by k . If we suppose $A - B$ to be a quantity as likely to be positive as negative, it follows from (103.), that the probability of $s(A - B)$ being as great as h , or greater, is

$$\int_h^\infty \varepsilon^{-\beta x^2} dx \times \sqrt{\beta \div \pi}, \text{ where } \beta = 1 \div 4sk''E^2,$$

$$\text{or } \frac{1}{2} \left(1 - \frac{2}{\sqrt{\pi}} \int_0^t \varepsilon^{-t^2} dt \right), \text{ from } t=0 \text{ to } t=h \div \sqrt{4sk''E^2}.$$

This is the probability of the result arising from ordinary error; if it be very small, then the complement to unity, which is very near unity, is the probability that there is some other cause of the difference. Supposing k'' unknown, the case most unfavourable to an external cause (excluding the supposition that the error and its probability increase together) is that all errors from $-E$ to $+E$ are equally likely. This gives

$$\phi\left(\frac{X}{E}\right) = \text{const.} = \frac{1}{2E} \quad k''E^2 = \int_0^E \frac{1}{2E} \cdot x^2 dx = \frac{E^2}{6},$$

or the most unfavourable value of the limit of integration is $h \div \sqrt{\frac{2}{3}sE^2}$. To take the instance given by Laplace: 400 days were chosen, throughout which the barometer did not vary 4 millimetres: so that, in this case,

* *Théorie*, &c. p. 343, 2ième. *Supplément*, &c. p. 42. *Méc. Cél.* liv. iii. No. 39, 40.

Theory of
Pro-
babilities.

we suppose $E=4$. The sum of the heights at nine in the morning exceeded those at four in the afternoon by 400 millimetres, giving an average of one millimetre. That this should have happened from mere error of observation, has only the probability $\frac{1}{2} \left(1 - \frac{2}{\sqrt{\pi}} \int \varepsilon^{-t^2} dt \right)$, from $t=0$ to $t=\sqrt{37\frac{1}{2}}$; a result of such exceeding

Theory of
Pro-
babilities.

smallness that the supposition of a diurnal variation of the barometer becomes insuperably probable.

(140.) Common sense dictates to us the notion that, of two causes which are not equally probable, the one most likely beforehand to have caused an event is most likely to have been the cause. From this notion (shown in (19.) to accord with the fundamental principles of the theory), we have the following theorem, already used: that if we consider each possible degree of probability as belonging to a state of things under which the event observed might have happened (which is all we here imply by a *cause*), and if the assumption of $x_1, x_2, \dots$ for the probabilities of the components of an event give $y=f(x_1, x_2, \dots)$ for the probability of the event happening under that status, the relative probability of such status having really existed is $f(x_1, x_2, \dots) \div \int f(x_1, x_2, \dots) dx_1 dx_2 \dots$. Or rather, $f \times dx_1 dx_2 \dots$ divided by $\int f \times dx_1 dx_2 \dots$ is the probability of the causal status being such that the chances of the components lie between x_1 and x_1+dx_1, x_2 and $x_2+dx_2, \&c.$ If $x_1, \&c.$ be independent of each other, the integral in the denominator must extend from $x_1=0$ to $x_1=1$, from $x_2=0$ to $x_2=1$, &c.; but if some of the variables depend on the rest, only those which are independent must be used as integrators. The most probable cause is that status which makes f a maximum: and it must be our object to determine (at least for one and two variables) what is the probability that $a_1, a_2, \&c.$ being the values at the maximum, the causal status is one in which the component probabilities lie between $a_1-\theta_1$ and $a_1+\theta'_1, a_2-\theta_2$ and $a_2+\theta'_2, \&c.$

(141.) But first, it is worth while to observe, that the argument in (89.) is reinforced by proving that the result is that* which makes the observed event most probable, as well as that which gives the estimated disadvantage equal to nothing. The maximum value of $\phi(A_1-x) \cdot \phi(A_2-x) \dots \phi(A_n-x)$ is ascertained from the following equations: $\chi x = \phi'x \div \phi x$ and $\sum \chi(A-x) = 0$. Assuming that the average satisfies this, we may by the same method, as in (89.), ascertain that $\chi x = 2cx$ or $\phi x = \varepsilon^{cx^2+c'}$, in which the condition of a maximum (as distinguished from a minimum) requires that c should be negative.

(142.) Let θ and θ' be so near and so small that $-T$ and T' (in (69.), altering the sign of the inferior limit), the values of t answering to $x=a-\theta$ and $x=a+\theta'$, differ by no more than a quantity of the order $1 \div \sqrt{\alpha}$: where α , as in the article cited, is such that the α th root of y does not contain considerable exponents. The equation there given then becomes

$$\int_{a-\theta}^{a+\theta'} y dx = \frac{1}{\sqrt{\pi}} \int_{-T}^{+T'} y dx \times \int_{-T}^{+T'} \varepsilon^{-t^2} dt + \text{terms of the order } \frac{1}{\alpha}, \&c.$$

The values of y corresponding to the limits of t are both zero: and it will generally happen that the values of x which make $y=0$ are 0 and 1: since practical cases are mostly those in which the observed event could not have happened with absolute certainty either for or against the event whose probability is x . It is sufficient if the

extreme values of y be very small. Let $\sqrt{\frac{1}{2}(T^2+T'^2)} = \tau$, and observe that using $-\tau$ and $+\tau$ for $-T$ or

$-\sqrt{\frac{1}{2}(T^2+T'^2)} + \frac{1}{2}(T^2-T'^2)$, and $+T'$ or $+\sqrt{\frac{1}{2}(T^2+T'^2)} - \frac{1}{2}(T^2-T'^2)$ is equivalent to a rejection of terms which are only of the order $1 \div \alpha$. Reject all such terms, and we have

$$\int_{a-\theta}^{a+\theta'} y dx \div \int_0^1 y dx = \frac{1}{\sqrt{\pi}} \int_{-\tau}^{+\tau} \varepsilon^{-t^2} dt.$$

But assuming $y=Y \varepsilon^{-t^2}$, as in (65.), and observing that $x=a$ gives $t=0, y=Y$, we have

$$t^2 = -\frac{1}{2} \frac{Y''}{Y} \theta^2 + A\theta^3 + \dots, \text{ whence } \tau = \theta \sqrt{-\frac{1}{2} \frac{Y''}{Y}} \text{ very nearly;}$$

or the probability of x lying between $a \pm L \sqrt{-\frac{2Y}{Y''}}$ is $\frac{1}{\sqrt{\pi}} \int_{-L}^{+L} \varepsilon^{-t^2} dt$.

(143.) When the observed event is compounded of two independent events, and y is the probability† that the observed event would have *à priori*, if x and x' were those of the components, then the probability which the observed event gives to x being contained between p and q , and x' between p' and q' , is (48.), (68.),

$$\frac{\int y dx dx' \text{ (from } x=p, x'=p' \text{ to } x=q, x'=q')}{\int y dx dx' \text{ (from } x=0, x'=0 \text{ to } x=1, x'=1)} \text{ or } \frac{\int \varepsilon^{-t^2-t'^2} dt dt' \text{ (limits specified below)}}{\int \varepsilon^{-t^2-t'^2} dt dt' \text{ (from } t=-\infty, t'=-\infty \text{ to } t=+\infty, t'=+\infty)}$$

(neglecting a factor which should multiply both the latter integrals) where $t=M^{-1}(M\theta+N\theta')$, $t'=M^{-1}(MP-N^2)^{-1}\theta'$, (supposing $x=a+\theta, x'=a'+\theta'$) are equations which connect simultaneous values of x and x' with those of t and t' . To this it is a sufficient approximation that $2MY, 2NY$, and $2PY$ should be $-Y'', -Y'$, and $-Y''$, being the values of the second differential coefficients of y , when $x=a, x'=a'$, or when y is a maximum ($=Y$). This gives us

* This is the foundation adopted by Gauss, in his *Theoria Motus*, &c.

† It is supposed, as generally happens, that y is 0, or very small when $x=0, x'=0$, or when $x=1, x'=1$.

Theory of
Pro-
babilities.

$$\theta' = \left(\frac{-2Y''Y}{Y''Y'' - Y'^2} \right)^{\frac{1}{2}} t', \quad \theta = \left(-\frac{2Y}{Y''} \right)^{\frac{1}{2}} t - \frac{(2Y)^{\frac{1}{2}} Y' t'}{\{-Y''(Y''Y'' - Y'^2)\}^{\frac{1}{2}}};$$

babilities.

whence the probability that

$$\left. \begin{array}{l} x \text{ will lie between } a \text{ and } a + \frac{t}{\sqrt{M}} - \frac{Nt'}{\sqrt{M(MP - N^2)}} \\ x' \text{ will lie between } a' \text{ and } a' + \frac{\sqrt{M} \cdot t'}{\sqrt{MP - N^2}} \end{array} \right\} \text{ is } \frac{1}{\pi} \int_0^t \int_0^{t'} e^{-t^2 - t'^2} dt dt'.$$

(144.) We shall now apply the preceding analysis to some instances connected with statistical inquiries. And first let there be two events possible, P and Q, and p being greater than q , let P have happened p times, and Q, q times. We can from (77.) ascertain the presumption, that the probability of P lies between $p \div (p+q) \pm k$, where k is not considerable. But we ask what is the presumption that the chance of P in a case yet to come is greater than that of Q. Let x be chance of P happening in any one instance. The probability of the observed event is $[p+q] \div [p] \cdot [q] \times x^p (1-x)^q$, and as in (142.) the presumption that the chance of P lies between 0 and $\frac{1}{2}$ is $\int_0^{\frac{1}{2}} x^p (1-x)^q dx \div \int_0^1 x^p (1-x)^q dx$, where the first integral is taken from $x=0$ to $x=\frac{1}{2}$. The method of (61.) will not apply to this case, in most instances, and that of (60.) must be employed. When $y = x^p (1-x)^q$, we find $v = x(1-x) \div \{p - (p+q)x\}$, which gives

$$\int_0^{\frac{1}{2}} y dx = \frac{1}{2^{p+q+1}(p-q)} \left\{ 1 - \frac{p+q}{(p-q)^2} + \dots \right\}; \text{ but } \int_0^1 y dx = \sqrt{2\pi} \frac{p^{p+\frac{1}{2}} q^{q+\frac{1}{2}}}{(p+q)^{p+q+\frac{1}{2}}},$$

from (48.) and (70.) We have, therefore, for the presumption that the event which has happened most often is *not* the more probable of the two,

$$\frac{(p+q)^{p+q+\frac{1}{2}}}{2^{p+q+1}} \cdot \frac{1}{p^{p+\frac{1}{2}} q^{q+\frac{1}{2}}} \cdot \frac{1}{\sqrt{\pi}(p-q)} \left\{ 1 - \frac{p+q}{(p-q)^2} \right\} \text{ very nearly.}$$

The most easy method of computing this is by the formula

$$\begin{aligned} \log \left\{ \left(\frac{p+q}{2} \right)^{p+q} \div p^p q^q \right\} &= -p \log \left(1 + \frac{p-q}{p+q} \right) - q \log \left(1 - \frac{p-q}{p+q} \right) \\ &= -(p+q) \left\{ \frac{1}{1.2} \left(\frac{p-q}{p+q} \right)^2 + \frac{1}{3.4} \left(\frac{p-q}{p+q} \right)^4 + \frac{1}{5.6} \left(\frac{p-q}{p+q} \right)^6 + \dots \right\}, \end{aligned}$$

formed by expansion and reduction of the terms in pairs, the first and second, third and fourth, &c. In the case where p and q differ so much that $p+q$ is small compared with $(p-q)^2$, the resulting presumption is very nearly

$$\frac{(p+q) e^{-c^2}}{4c \sqrt{pq\pi}}, \text{ where } c = \frac{p-q}{\sqrt{2}(p+q)} : \text{ which is a very small quantity.}$$

The remainder of unity is the presumption that the event which happens most often is the more probable. But when p and q are so near each other that the preceding does not apply, we find, as in (142.), that $\int_0^{\frac{1}{2}} y dx \div \int_0^1 y dx$ is $\int_0^{\frac{1}{2}} e^{-t^2} dt \div \sqrt{\pi}$, where the limits of the integral require examination. Taking $y = x^p (1-x)^q$, where p is the greater, we find that in $y = Y e^{-t^2}$, Y is derived from $x = p \div (p+q)$, or x is more than $\frac{1}{2}$. If, then, we integrate from $x=0$ to $x=\frac{1}{2}$, we do not get so far as the maximum value of y ; whence we must assume $t = +\infty$ as the limit corresponding to $x=0$, and $t = -\infty$ to $x=1$. Since $Y = p^p q^q \div (p+q)^{p+q}$, we have $\left\{ \frac{1}{2} (p+q) \right\}^{p+q} \div p^p q^q$ for the value of e^{-t^2} , corresponding to $x = \frac{1}{2}$. Integrate (to preserve a positive sign,

reverse* the limits) from $t = (p-q) \div \sqrt{2}(p+q)$ to $t = +\infty$, using the value of t derived from the first term of the preceding series. We have then the presumption, that the most frequent event is not the most probable.

(145.) Let there be two sets of $p+q$ and $p'+q'$ events, and let p and p' be the number of times which P happens, and q and q' the number of times which Q happens. Also let $p' \div q'$ be greater than $p \div q$. Required the presumption, that the probability of P under the first circumstances is greater than under the second.

Return to (77.), making $c = \sqrt{(p+q)^3 \div 2pq}$ and $c' = \sqrt{(p'+q')^3 \div 2p'q'}$, we find that the several probabilities of P lying between $a+\theta$ and $a+\theta+d\theta$ in the first, and between $a'+\theta'$ and $a'+\theta'+d\theta'$ in the second, are $\sqrt{c} \div \pi e^{-c^2 \theta} d\theta$ and $\sqrt{c'} \div \pi e^{-c'^2 \theta'} d\theta'$, a and a' being $p \div (p+q)$ and $p' \div (p'+q')$. If, then, we multiply these together, make $a'+\theta' = a+\theta+t$, and make θ' and t vary together from $t=0$ to $t=\infty$, we have, for a given value of θ , the presumption that $a+\theta$ has the corresponding value, and $a'+\theta'$ a greater. Then, integrating with respect to θ , from $\theta=-\infty$ to $\theta=+\infty$, we have the total presumption that $a'+\theta'$ is greater than $a+\theta$. That is, we must find (78.)

* The ambiguity of sign in the value of $\int y dx$ in (65.) has reference to this circumstance.

Theory of
Pro-
babilities.Theory of
Pro-
babilities.

$$\frac{cc'}{\pi} \int_{-\infty}^{+\infty} \int_0^{\infty} \epsilon^{-c^2 t^2 - c'^2 (\theta + t - a' + a)^2} d\theta dt, \text{ or } \sqrt{\frac{k}{\pi}} \int_0^{\infty} \epsilon^{-k^2 (t - a' + a)^2} dt,$$

(where $k^2 = c^2 c'^2 \div (c^2 + c'^2)$); this is $\frac{1}{\sqrt{\pi}} \int_{-L}^{\infty} \epsilon^{-t^2} dt$, where $L = k(a' - a)$, which is also

$$\frac{1}{2} + \frac{1}{\sqrt{\pi}} \int_0^L \epsilon^{-t^2} dt.$$

(146.) The preceding questions may be easily applied to the determination of the presumption, that the probability of a child to be born shall be a male rather than a female, by means of the recorded births in any country. But this is a question of pure curiosity compared with the following. The method of forming tables of mortality is (where it can be done) by observing what proportions of a number of individuals remain after one, two, &c. years. Supposing a table to be formed which should thus represent the career of 1000 individuals, it is obvious, 1. That the value of that table goes on diminishing as the number of individuals composing it diminishes. 2. That it must be a question how far that number itself is a sufficient guarantee for the presentation of something like an average of the whole of the class in question. We now ask, supposing that of p status of the same kind, q or λp are left at the end of a given time, what presumption is thereby afforded that at another trial, of p' status, some number between $q' \pm z$, or $\lambda p' \pm z$ a given number, shall be left at the end of a second such time. If x had been the *a priori* probability that any one of the first status should have lasted out the time, the consequent probability of the observed event would have been (No. of combinations of q out of p) $\times x^q (1-x)^{p-q}$, and the probability of the proposed event (on the supposition that $q' + z$ exactly are left) arising out of the possibility of that particular presumption being correct, will be

$$(\text{No. of combinations of } q' + z \text{ out of } p') \times \frac{x^q (1-x)^{p-q}}{\int_0^1 x^q (1-x)^{p-q} dx} \times x^{q'+z} (1-x)^{p'-q'-z};$$

so that the required result is

$$\frac{[p]}{[q' + z][p' - q' - z]} \frac{\int_0^1 x^{q+q'+z} (1-x)^{p+p'-q-q'-z} dx}{\int_0^1 x^q (1-x)^{p-q} dx}.$$

Write for q and q' their values λp and $\lambda p'$, and use the formulæ

$$[a] = \sqrt{2\pi} a^{a+1} \epsilon^{-a}, \quad \int_0^1 x^p (1-x)^q dx = p^{p+1} q^{q+1} (p+q)^{-p-q-3}$$

which gives, after reduction, the following result:

$$\frac{1}{\sqrt{2\pi}} \sqrt{\frac{p}{p'(p+p')(\lambda-\lambda^2)}} \left(1 + \frac{z}{\lambda(p+p')}\right)^{\lambda(p+p')+1+z} \left(1 + \frac{z}{\lambda p'}\right)^{-\lambda p' - 1 - z} \times \{\text{The same functions of } 1-\lambda \text{ and } -z\}.$$

But $(1 + Az)^{Bz+C} = \epsilon^{(Bz+C)(Az - \frac{1}{2}A^2z^2)} = \epsilon^{(AB - \frac{1}{2}A^2C)z^2} (1 + ACz)$ nearly;

and in the four factors preceding, making $c = p \div 2p'(p+p')(\lambda-\lambda^2)$,

$$\Sigma \left(AB - \frac{1}{2} A^2 C \right) = -c - \frac{1}{4} \left(\frac{1}{(p+p')^2} - \frac{1}{p'^2} \right) \left(\frac{1}{\lambda^2} + \frac{1}{(1-\lambda)^2} \right), \quad \Sigma AC = \frac{1}{2} \frac{p^2}{p'(p+p')} \cdot \frac{2\lambda-1}{\lambda-\lambda^2};$$

and rejecting the term which follows $-c$, as being of an order inferior to c , the probability in question becomes $\sqrt{c \div \pi} \epsilon^{-cz^2}$. We reject the term containing ΣAC , both on account of its smallness, and because it presently disappears in integration. Therefore $\sqrt{c \div \pi} \epsilon^{-cz^2} dz$ is the probability that the number left will lie between $\lambda p' + z$ and $\lambda p' + z + dz$, and $\sqrt{c \div \pi} \int_{-L}^{+L} \epsilon^{-cz^2} dz$, that it will lie between $\lambda p' \pm L$.

If we suppose the original number p from which λ is determined to be very considerable with respect to p' , then $c = 1 \div 2p'(\lambda - \lambda^2)$, and we may easily draw the following conclusions: 1. That a table of mortality formed from finite data may be applied to any contingencies, and that the theory of the probable errors is the same as that of the errors of observations. 2. That the specific weight of a table is the greater, the less the number of persons to whose lives it is to be applied. 3. That presuming an application of the table to a number of persons bearing a given proportion to the number in the table, the specific weight is inversely as the number of deaths in the table $\times (\lambda - \lambda^2)$. If λ be near to unity, as is usually the case, let $\xi = 1 - \lambda$, and the specific weight is then as inversely as (number of deaths) $\times \xi$, nearly.

This result seems contrary to common sense: but examination will show that it coincides with former results. For a given amount of business, the contingency being the number who shall remain alive at the end of a given term, the greater the number of previous observations made, the greater is the confidence which may be placed in the results. But if an office dealing in such contingencies, and adding but a small security fund to the results of tables, were to double its engagements on the strength of having a double quantity of observations, without increasing the per-centage of the security fund, it would not be so safe as before. The observations must be increased in a greater proportion than it is proposed to increase the engagements. But 1. Such contingencies are not common. 2. The per-centage which is added to the results of tables is at present amply sufficient. Nevertheless, an office whose gains or losses depend entirely on the number of survivors being within or without given limits at the end of a given term, might be ruined by over confidence in its tables, derived from the extensiveness of the observations.

Theory of
Pro-
babilities.

(147.) Now suppose it to have been observed that there were p status at the commencement of an observation, of which λp lasted through a first interval, μp through a second, and νp through a third. The probability that of p' of such status, $\lambda p' + z$ shall last through the first interval, has been determined. This event having happened,

Theory of
Pro-
babilities.

the probability that $\frac{\mu}{\lambda}(\lambda p' + z) + u$ shall last through the second interval has the specific weight $\lambda p \div 2p' (p + p')$ ($\mu\lambda - \mu^2$), if z be neglected as compared with p' or $\lambda p'$. Again, this second event having happened, the probability that $\frac{\nu}{\mu}(\mu p' + \frac{\mu}{\lambda}z + u) + v$ shall last to the end of the third interval has the specific weight $\mu p \div 2p' (p + p')$ ($\nu\mu - \nu^2$). Hence the probability of the three events happening (within dz , du , and dv), calling these specific weights c , c' , c'' , is

$$\sqrt{\frac{c c' c''}{\pi^3}} \varepsilon^{-cz^2 - c'u^2 - c''v^2} dz du dv, \text{ or } \sqrt{\frac{c c' c''}{\pi^3}} \varepsilon^{-cz^2 - c'(z' - \frac{\mu}{\lambda}z)^2 - c''(z'' - \frac{\nu}{\mu}z')^2} dz dz' dz'',$$

making $\lambda p' + z$, $\mu p' + z'$, and $\nu p' + z''$ the limits.

(148.) The problem in (146.) may be applied to any event whatever, of which the single probabilities (supposed equal) can be approximately found. For instance, n marriages are contracted, in which all the men are of the same age, and also all the women. If the law of mortality be that λ and λ' be the surviving fractions of the numbers of men and women at the end of a years, the probability of any given marriage still continuing at the end of that term is $\lambda\lambda'$, and $n\lambda\lambda'$ is the most probable number to be then in existence. The probability that the number lies between $n\lambda\lambda' \pm L$ is $\sqrt{c \div \pi} \int \varepsilon^{-ct^2} dt$ from $t = -L$ to $t = +L$, where c is the reciprocal of $2n(\lambda\lambda' - \lambda^2\lambda'^2)$. The result of Laplace, corrected,* is equivalent to this.

(149.) We shall now consider the single or joint duration of a number of lives. If, at a given age, the probability of a life lasting x years be ϕx , we have to alter the result of (107.) as follows. In the article cited, there were errors of either sign, both to be interpreted as positive. Consequently, the real law of facility there employed was $2\phi x dx$, which is the $\phi x dx$ of this article. Hence, for $2k'$ and $2k''$ we must write k' , k'' , and (the limits of possible drawing (86.) being infinite) we have $1 \div \sqrt{\pi} \int \varepsilon^{-t^2} dt$, from $t = -L$ to $t = +L$, for the probability of the sum of s lives lying between $k's \pm L \sqrt{2s(k'' - k'^2)}$. But $k's$ is the sum presumed from the law of the tables, whence the probability of the departure from tables being $L \sqrt{2s(k'' - k'^2)}$ is $1 \div \sqrt{\pi} \int \varepsilon^{-L^2} dL$. The specific weight is, therefore, the reciprocal of $2s(k'' - k'^2)$, and the mean risk of error is the square root of $s(k'' - k'^2) \div 2\pi$. Dividing this by s , to find the mean risk on a single life, and remembering the value of k'' (the $2k''$ of (106.)), we have the following result: s being the number alive at the commencement, and $s_1, s_2, \&c.$ those remaining at the end of successive years,

$$\text{Mean risk of duration of life} = .39894 \sqrt{\frac{\text{mean square of duration} - (\text{mean duration})^2}{s}}.$$

See (115.), of which this is a case, with the mean risk deduced instead of the probable error. It appears that correctness of observation is of more importance than large numbers. *Cæteris paribus*, one table is twice as good as another, when there are four times as many events recorded in it.

(150.) The same result applies to other cases, and by way of recapitulation we may now state the following theorem.

Let there be s status, each of which has the chance λ of outlasting a given term: it being necessary that λ should diminish without limit as the term increases without limit. Then the probability that at the end of the term the number of status remaining should lie between $s\lambda \pm L \sqrt{2s(\lambda - \lambda^2)}$ is $(1 \div \sqrt{\pi}) \int \varepsilon^{-t^2} dt$, from $t = -L$ to $t = +L$. The mean duration of the status is $\int_0^\infty \lambda x dx$, λ being a function of x , the time elapsed from the common commencement; and the probability of any one status lasting for a time lying between

$$k' \pm L \sqrt{\frac{2(k'' - k'^2)}{s}} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-L}^{+L} \varepsilon^{-t^2} dt \quad \{k' = \int_0^\infty \lambda x dx, \quad k'' = \int_0^\infty \lambda x^2 dx\},$$

where k' and k'' are approximately found by taking the actual mean, and the actual mean square, of a large number of observed durations. Again, the mean risk of error in estimating a single duration is $.39894 \sqrt{(k'' - k'^2) \div s}$, and the probable error is $.67449 \sqrt{(k'' - k'^2) \div s}$.

(151.) It is to be regretted that the consequences of this general theory have never been put in so popular a form as to be accessible to the majority of those who are engaged in the construction of tables† of contingencies for practical use. In most contingency offices, all their different kinds of dealings are considered as equally likely to depart from the tables one way or the other, in providing the necessary overplus for security. This prevents

* The solution of Laplace (p. 415—418) is highly characteristic of this most powerful, but unsymmetrical, architect. In page 418, the solution of a definite problem actually appears with an indeterminate quantity (p'), altogether independent of the conditions of the problem. But a previous supposition (subsequently neglected) requires that this quantity should be very great, which reduces the result to the one which we have given.

† Not being well able to decide upon the relative importance of small details, calculators on this subject have hitherto judiciously presented their results such as they ought to be if the tables were mathematically exact, and to the nearest farthing. But more extended views on the subject of probabilities, and on the nature of observations in general, would have caused the time which has been wasted in carrying out annuities to many more decimals than the data are good for, to be employed in apportioning the risks of fluctuation, by estimation of the mean risks of the tables.

Theory of
Pro-
babilities.Theory of
Pro-
babilities.

an equitable partition of the risks of fluctuation. Suppose, for example, to simplify the question, an office which undertakes to grant annuities single and joint, upon lives aged twenty. The observations on which the office tables are founded are the history of a large number s of such lives, containing $\frac{1}{2}s(s-1)$ pairs. The mean duration, single and joint, and the mean square of duration, are ascertained sufficiently for the purpose without any

great difficulty. Calling these k'_1 and k'_2 , and k''_1 and k''_2 , we have $\sqrt{(k''_1 - k'^2_1) \div s} : \sqrt{(k''_2 - k'^2_2) \div \frac{1}{2}s(s-1)}$

for the proportion of the mean fluctuations against the office in the case of single and joint lives. Commercial prudence points out that the fluctuations should be treated as if they must necessarily be against the office. This proportion is the proportion of the per-centages to be added to the results of the tables, for security. It is desirable, for the sake of equitable distribution, that something like this proportion should be preserved; as it certainly will be when insurers of all kinds come to be aware that, as the matter stands, those concerned in simple risks pay a part of a security fund which should fall somewhat more heavily on the complicated risks.

(152.) We have hitherto considered nothing but the probabilities arising out of proposed circumstances: we now come to the appreciation of the probable gain or loss, on the supposition that every possible case which can happen is attended with a given amount of one or the other. Returning to the principle enunciated in (26.), we lay it down that the *mathematical* advantage arising from the chance p of a gain v is expressed by pv ; and also that it is only when the parties opposed (for such there must be, since the gain of one must be the loss of another) are similarly situated in regard to the value of an absolute gain or loss, that the mathematical advantage is a fair estimate of the thing required.

(153.) We may also consider questions of absolute gain or loss as questions of simple chances, in which certainty is no longer represented by 1, but by v : it being known that when v is negative, the contingent gain becomes a contingent loss, and *vice versa*. We may also see that a negative answer to a question of probabilities denotes that the solution gives a chance of an event diametrically opposed to the one presumed in the mathematical reduction of the problem.

(154.) If we multiply every possible loss or gain by its chance, and add the results with their proper signs, it follows that the sum is the value of the prospect, or what we may call the *mean advantage*. In the case of a succession of single events, each of which must be either A or B, the chances for these being q and $1-q$, let us suppose that A and B bring the gains v and μ every time they occur; consequently, in s trials, if A occur i times and B occur $s-i$ times, the resulting gain is $iv + (s-i)\mu$, or $s\mu + i(v-\mu)$. Multiply this by the probability of the event, or by $\{[s] \div [i] \cdot [s-i]\} q^i (1-q)^{s-i}$, which taken for every value of i from $i=0$ to $i=s$, and each case multiplied by its resulting benefit, gives the same result as the following expression, if t be made $=1$ after differentiation,

$$s\mu (qt+1-q)' + (v-\mu) \frac{d}{dt} (qt+1-q)'; \text{ which is } s\mu + sq(v-\mu),$$

or $q \cdot sv + (1-q)s\mu$ is the mean advantage required.

In the case of mathematical equality, μ and v must be of opposite names, and in the proportion of q to $1-q$. Again, from (74.), the probability of A occurring a number of times, which lies between $sq \pm l$ (extremes inclusive) is

$$\frac{2}{\sqrt{\pi}} \int_0^t e^{-t^2} dt + \frac{t e^{-t^2}}{l\sqrt{\pi}}, \text{ where } t = \frac{l}{\sqrt{2sq(1-q)}}.$$

But this is the probability of the actual benefit derived lying between $(sq \pm l)v + (s-sq \mp l)\mu$, or $M \pm l(v-\mu)$, where M is the mean advantage.

(155.) The most usual case is where v and μ are of opposite names; and we may suppose μ to be a loss, and therefore negative. We are now led to the appreciation of the advantage arising from the *division of risks*. Let us suppose that, instead of making s ventures, each of which is either a gain of v , or a loss of $-\mu$, a merchant makes ks ventures, each of which is either a gain of $v \div k$, or a loss of $-\mu \div k$. The mean advantage remains unaltered, but the probability of a given departure from it is altered in his favour, as follows. Let l' be the value of l , which gives the same value of t as before: then $l' = l\sqrt{k}$ and $l(v-\mu)$, and $l\sqrt{k}(v-\mu) \div k$, or $l(v-\mu) \div \sqrt{k}$ are the limits of departure for which there are the same chances. Consequently whatever may be the risk of ruinous fluctuation in embarking a certain quantity of capital in each of a certain number of similar speculations, it is halved by employing one-fourth as much in each of four times as many speculations, and so on.

(156.) Mercantile men are perfectly aware of the general truth of this principle, but they very often imagine that they *halve* the risk by *doubling* the number of ventures, which is not true. And the rest of the world, in judging of the various commercial schemes which arise, regards them as a symptom of a propensity to gamble. But this is not the case: a monied man who takes the run of the market, and makes large numbers of different investments, has only to consider the general features of the time, and to ascertain whether the prevailing disposition is on the whole regulated by prudence and calculation. If he see this attested by the decided success of a large majority of undertakings, it is, though not unimportant, yet of minor importance, whether he judge wisely or not in one or two instances. He can, with no unusual degree either of prudence or knowledge, make his success highly probable.

(157.) We shall now suppose that any number of different events may happen at every trial, of which the probabilities are a_1, b_1, c_1 , &c. at the first, a_2, b_2, c_2 , &c. at the second, and so on; so that we have generally $a + b + c + \dots = 1$. Again, suppose that at the first trial the benefits contingent on the different ways of

Theory of Probabilities. happening are λ_1, μ_1, ν_1 , &c., at the second λ_2, μ_2, ν_2 , &c. If, then, we suppose s trials, and multiply together the Theory of Probabilities. s expressions of the form $ax^\lambda + bx^\mu + cx^\nu + \dots$, we shall have a series of terms of the form Ax^K , where K is one of the possible results as to benefit, and A the probability of obtaining it. Let M be the mean advantage of s trials; whence, as in (102.), we find the chance of the advantage of s trials being $M+l$ to be the term independent of x in the development of

$$x^{-(M+l)} (a_1 x^{\lambda_1} + b_1 x^{\mu_1} + \dots) (a_2 x^{\lambda_2} + b_2 x^{\mu_2} + \dots) (\dots) (a_s x^{\lambda_s} + \dots),$$

or, assuming $x = \varepsilon^{\sqrt{-1}}$, we must integrate the preceding from $\omega = -\pi$ to $\omega = +\pi$, and divide by 2π . But since $a+b+\dots=1$, the several factors preceding are all of the form $1 + (a\lambda + b\mu + \dots) \omega \sqrt{-1} - \frac{1}{2} (a\lambda^2 + b\mu^2 + \dots) \omega^2 - \dots$, and their logarithms are of the form $(a\lambda + b\mu + \dots) \omega \sqrt{-1} + \frac{1}{2} \{ (a\lambda + b\mu + \dots)^2 - (a\lambda^2 + b\mu^2 + \dots) \} \omega^2 + \dots$. Consequently, passing from logarithms to their exponentials, and remembering that M must be $\Sigma (a\lambda + b\mu + \dots)$, where Σa means $a_1 + a_2 + \dots$; and making

$$2sk^2 = \Sigma \{ (a\lambda^2 + b\mu^2 + \dots) - (a\lambda + b\mu + \dots)^2 \},$$

we have for the probability in question

$$\frac{1}{2\pi} \int_{-\pi}^{+\pi} \varepsilon^{-l\omega\sqrt{-1} - sk^2\omega^2 - \dots} d\omega,$$

the integration of which, when s is a considerable number, will not be materially affected by our making the limits infinite; thus in $\int \varepsilon^{-sx^2} dx$, from $x = -h$ to $x = +h$ depends upon $\int \varepsilon^{-x^2} dx$, from $x = -h\sqrt{s}$ to $x = +h\sqrt{s}$. And we may neglect the terms which contain ω^3 , &c. on principles explained in (89.) Consequently (78.), the probability of the total resulting gain being $M+l$ is

$$\frac{1}{2\sqrt{\pi sk^2}} \varepsilon^{-\frac{l^2}{4sk^2}}: \text{ which gives } \frac{1}{\sqrt{4\pi sk^2}} \int \varepsilon^{-\frac{t^2}{4sk^2}} dt, \text{ from } t = -l \text{ to } t = +l,$$

for the probability of the resulting gain lying between $M \pm l$. But this last step is on the supposition that the number of partial contingencies composing each event is so large, and the gain of each so small, that the definite integration will be nearly equivalent to the summation which suggests it: or else that the number s is so large that any gain lying between $M \pm l$ may be obtained either exactly or nearly, in many different ways. The result is that the probability of the resulting gain lying between

$$\Sigma (a\lambda + b\mu + \dots) \pm 2k\sqrt{s}.l \text{ is } \frac{1}{\sqrt{\pi}} \int_{-l}^{+l} \varepsilon^{-t^2} dt$$

$$k^2 = \frac{1}{2s} \Sigma \{ (a\lambda^2 + b\mu^2 + \dots) - (a\lambda + b\mu + \dots)^2 \}.$$

In (154.) we see a particular case of this, with the first rejected term, owing to the process in (74.) having been carried further than is necessary for sufficient approximation. This term, as in the example of (74.), is always a small part of the whole, when s is considerable.

(158.) Where there are only two contingencies in each trial, we find that the probability of the result lying between

$$\Sigma \{ a(\lambda - \mu) + \mu \} \pm l \sqrt{2a(1-a)(\lambda - \mu)^2 s} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-l}^{+l} \varepsilon^{-t^2} dt,$$

and the substitution of the factor s for the symbol Σ converts the general case into that in which all the trials are repetitions of the same.

(159.) Suppose s lives of the same age to be insured for £Q each, of which the law of mortality is as follows: of K lives of the given age, K_1 remain at the end of a year and K_n at the end of n years: now P being the premium paid by each, what is the probability that the present value of the ultimate gain or loss of the insurance office will lie between given limits?

It is impossible here to consider the life of each individual, and its total result, as one event with respect to the office, for it is made up of all the chances connected with the different years. Considering an individual A , and the period of time between n and $n+1$ years elapsed from the moment of completing the insurances, we have the three following cases: 1. A may overlive the period, in which case the office gains P at the beginning of the year: or, looking at every loss and gain with reference to its value at the time of making the bargain, it gains Pv^n , where v is the present value of £1, to be paid a year hence. The chance of this event is $K_{n+1} \div K$, which call p_{n+1} . 2. A may die during the year; in which case the office gains P at the beginning, and loses Q at the end, of the period; that is, loses $Qv^{n+1} - Pv^n$. The chance of the event is $(K_n - K_{n+1}) \div K$, or $p_n - p_{n+1}$. 3. A may have died before the period begins; in which case the office neither gains nor loses, or this case may be omitted. Hence the portion of the mean result contributed by every individual is the sum of all his terms of the form

$$p_{n+1} Pv^n - (p_n - p_{n+1}) (Qv^{n+1} - Pv^n), \text{ or } Pp_n v^n - (p_n - p_{n+1}) Qv^{n+1}.$$

This is exclusive of $P+E$ certainly paid down at the beginning, where E is a fee demanded at entrance. And P

Theory of Probabilities. itself is not the gross premium actually paid, but the remainder after a certain proportion is deducted for expenses of management. The mean result, therefore, from each individual is ($p_0=1$), Theory of Probabilities.

$$P + E + Pp_1v + Pp_2v^2 + \dots - (1-p_1)Qv - (p_1-p_2)Qv^2 \dots$$

The tabular value of an annuity of £1 on the life of each party is $p_1v + p_2v^2 + \dots$. Call this A : then the preceding becomes $E + P(1+A) - Qv(1+A) + QA$. The office premium is generally calculated as in (36.), with the addition of a per-centage. Let f be the fraction of unity in this per-centage, and we have $P = \{Qv(1+A) - QA\} (1+f) \div (1+A)$; where in f may be included the diminution allowed for expenses of management. This reduces the preceding expression to $E + fQ(v + vA - A)$, and s times this latter sum is the mean result.

The component of k^2 , in (157.), which arises from the period between the completion of n and $n+1$ years, is

$$p_{n+1}P^2v^{2n} + (p_n - p_{n+1})(Qv^{n+1} - Pv^n)^2 - \{Pp_nv^n - (p_n - p_{n+1})Qv^{n+1}\}^2 \\ = v^{2n} \{ (Qv - P)^2 p_n - Qv(Qv - 2P)p_{n+1} + 2Qv(Qv - P)p_n p_{n+1} - (Qv - P)^2 p_n^2 - Q^2 v^2 p_{n+1}^2 \}.$$

Summing this expression with respect to an individual insurer, an easy method presents itself of providing what we will call *fluctuation tables*, in addition to the common tables. A new rate of interest must be taken, such that v^2 , and not v , may be the present value of one pound receivable a year hence (for 4 per cent. 8 per cent. will do.) With this rate must be calculated tables of annuities on single lives, on two joint lives of equal ages, and on two joint lives in which the older is a year in advance of the younger. Let $\bar{A}$, $\bar{\bar{A}}$, $\bar{AA}$, and $\bar{\bar{AA}}$ represent the values of these annuities for £1 per annum, increased by one year's purchase, (see Note to (34.)), where the single bar indicates the age of a party being that of the problem, and the double bar a year older. Hence we have, S denoting summation with respect to successive years of the same individual (from $n=0$ upwards),

$$Sp_nv^{2n} = \bar{A}, \quad Sp_{n+1}v^{2n} = p_1\bar{\bar{A}}, \quad Sp_np_{n+1}v^{2n} = p_1\bar{AA}, \quad Sp_n^2v^{2n} = \bar{AA}, \quad Sp_{n+1}^2v^{2n} = p_1^2\bar{\bar{AA}}.$$

Let the following expression be denoted by K^2 ,

$$(Qv - P)^2 \bar{A} + 2Qv(Qv - P)p_1\bar{\bar{AA}} - Qv(Qv - 2P)p_1\bar{\bar{A}} - (Qv - P)^2 \bar{AA} - (Qv)^2 p_1^2 \bar{\bar{AA}};$$

then sK^2 is the factor Σ (&c.) in the value of k^2 in (157.), and therefore $k^2 = \frac{1}{2}K^2$. Hence the probability that the ultimate gain of the office from s individuals shall lie between

$$sE + sfQ(v + vA - A) \pm Kl\sqrt{2s} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-l}^{+l} e^{-t^2} dt,$$

and the same that the average profit from each individual lies between $E + fQ(v + vA - A) \pm Kl\sqrt{2/s}$.

(160.) Let us now see how the case would be altered if each individual paid down the whole present value of his insurance, instead of yearly premiums. This case may be deduced from the former by supposing $P=0$, and E to be the present value paid down + its former value.

Beginning the problem again on the supposition that the present value demanded is $Q(v + vA - A)(1+f)$, we find the mean advantage of the office the same as before; while the value of K^2 , which call K_1^2 , is now deduced from K^2 by making $P=0$, which gives

$$K^2 - K_1^2 = P^2(\bar{A} - \bar{AA}) + 2PQvp_1(\bar{\bar{A}} - \bar{AA}) - 2PQv(\bar{A} - \bar{AA}).$$

Now the difference of $\bar{A} - \bar{AA}$ and $\bar{\bar{A}} - \bar{AA}$ (necessarily positive quantities) will be trifling; and the sign of $P - 2Qv(1-p_1)$ will decide that of the preceding. And l and s remaining the same, the limits of fluctuation for which there is a given probability increase with K . When the preceding is *positive*, premiums are most favourable to fluctuation: when *negative*, total payments. And *cæteris paribus*, the larger p_1 is, that is, the better the class of lives, the more will the former method favour fluctuation, as compared with the latter. But these conclusions must not be applied to very old lives, without examination of $\bar{A}$, &c. This question is immaterial at present, owing to the rarity of the occurrence of an insurance being completely paid for at the moment of completing the bargain.

The same considerations may be applied to the question of a number of annuities purchased, or any other of the kind, and generally the facilitation of the question of probable fluctuations will require the calculation of ordinary life-tables at different rates of interest, connected with the one on which the primitive tables are constructed. At present, however, owing to the tables in use being always indicative of a much lower (or in the case of reversions, higher) rate of mortality than is expected, and the rarity of knowledge upon the higher parts of this theory, it is useless to expect any adoption of results founded upon the calculation of fluctuations.

(161.) From the preceding it appears that the *mathematical* advantage is greatly in favour of the insurance offices, and most certainly it ought to be so. It is by giving the office mathematical certainty of a large profit that the individual insurers buy the moral security which they have of receiving the stipulated benefits. But while we take this opportunity of declaring that the directors of any contingency office would be most justly open to censure if they attempted to hit the line of mathematical security exactly, or very nearly: we must also say, that there is no need to help the proprietors of a nominal capital to any part of the large profits which are accumulated to deaden the effects of fluctuation. Let the insurers share this among themselves; that is, let them be mutual insurers, fearless of fluctuation, because they have established a sufficient fund to meet it; and withdrawing the surplus of this fund, as it accumulates, for their own use and benefit.

(162.) Instead of the probabilities being absolutely given, let p events have been first observed, of which

Theory of
Pro-
babilities.

θp have happened, so as each to give a gain ν , and the rest so as each to give a gain μ , these being the only possible cases. Then, by (146.), the probability that of p' cases yet to come the number which gives ν will lie between

Theory of
Pro-
babilities.

$$\theta p' \pm L \sqrt{\frac{2p'(p+p')(\theta-\theta^2)}{p}} \text{ is } \frac{1}{\sqrt{\pi}} \int_{-L}^{+L} e^{-t^2} dt,$$

which is also the chance of the total result, as to benefit, lying between

$$\{\theta\nu + (1-\theta)\mu\} \pm L(\nu-\mu) \sqrt{\frac{2p'(p+p')(\theta-\theta^2)}{p}}.$$

On comparing this with the similar case in (154.), and supposing θ absolutely given as the probability of the gain ν in each instance, we see that the limits of fluctuation for which there is the probability just found, are $\pm L(\nu-\mu)\sqrt{2p'\theta(1-\theta)}$, or less than the preceding in the ratio of $\sqrt{p}$ to $\sqrt{p+p'}$. That is, the assumption of a probability from observation of p past events, made an hypothesis for calculating the chances of p' events yet to come, must be considered as likely to produce larger fluctuations than happen in cases where the same probability is absolutely known, in the proportion of $\sqrt{p+p'}$ to $\sqrt{p}$.

(163.) We now come to the question of gain or loss, relatively and not absolutely considered, as in (42.). The value of money must be considered absolutely in all transactions between man and man; that is, the terms of every bargain must express definite sums. But in the previous consideration, which every one must give, as to the policy of a proposed bargain, it is notoriously false that any practical view of the subject considers money absolutely. The supposition, therefore, of the mere mathematical gain or loss must be abandoned, whatever may be thought as to the propriety of one or another substitute. The theorem in (42.) gives results decidedly nearer the truth than any results of the view just abandoned: but a little consideration will show that it must be modified before it will yield the best representation which we can give of relative value. That a man with five hundred pounds will think *less* of five shillings than another of the same temperament who has only one hundred pounds, is readily admitted: but that the first will look upon five shillings just as the second does upon one, may be doubted. But we must observe, that no person looks upon an outlay of money with reference to the whole of his own property, but considers the purpose for which the expense is to be incurred, and the proportion which it bears to the greatest possible sum he can devote to that or similar objects. An amateur of painting, of very large fortune, will give a thousand pounds for one work of a great master; while another person, of the same fortune, intending to lay out one thousand pounds in pictures, will not buy the single picture, but will prefer twenty at a cheaper price. In the two cases, the value of a thousand pounds is different; in the first it is only a small part of the fund out of which it is to come; in the second it is the whole. Suppose it to be admitted that the relative values of small and equal additions to the similar funds of two persons are inversely as the amounts of the funds, which is not only the most natural supposition, but one which seems not more liable to objection as giving too much, than as giving too little. In that case, the fund being x , the value of dx is of the form $kdx \div x$, and the value of the whole fund is $k \log x + h$, where h is a constant to be determined. But it must be observed, that the whole process fails when x becomes very small, and it is besides easily shown that in such case the natural and obvious character of the supposition entirely disappears.

Imagine a small fund in the possession of an individual, out of which an expense of serious magnitude is proposed. If this fund be the sole means of the individual, the value of its several parts will be large. But if the purpose in question be the support of life, we must place in the fund a money representation of all that the individual can do to maintain himself when his money is gone. If that small fund were really the whole support of the individual, so that he must undoubtedly perish after its extinction, there would be no objection to the formula $k \log x + h$, taken from $x=0$, considered as representing the whole value of the fund. But no such case arises, so that in fact when we speak of $kdx \div x$ as representing the relative value of dx , we are considering dx as an accession to a fund already existing, and of such magnitude as not to present an extreme case. Under these circumstances, the above valuation of dx is of a highly probable character, and $k \log x + h$ is the necessary mathematical consequence of it, as the representative of the relative value of x . Laplace calls x the *fortune physique*, and $k \log x + h$ the *fortune morale*, for which we shall substitute the terms absolute and relative values.

(164.) The preceding method of estimation will require us to reconsider the method of estimating probable losses and gains. When we speak only of absolute values, the formula $(a+b)-b=a$, and the fundamental axiom from which it springs, cause many simplifications of process. For instance, suppose a man who has a , has also the chance p of gaining b . We estimate his absolute advantage at $a+pb$. But we may also proceed as follows. An event to come will leave him either with a or $a+b$, the chances of which are $1-p$ and p . Hence his expectation is $(1-p)a + p(a+b)$, which is $a+pb$. But suppose that the values of a and $a+b$ are represented by ϕa and $\phi(a+b)$; then, except only where $\phi a = \text{const.} \times a$, the value of a sum is no longer the sum of the values. We have then a lottery in which a proportion $1-p$ of the tickets is marked ϕa , and the remaining portion p is marked $\phi(a+b)$. If a very large number of persons draw, the average drawing will have a very high probability of being excessively near to $(1-p)\phi a + p\phi(a+b)$. In this form we must state the preceding sentence, for otherwise it would appear as if we were adding values to values to produce the value of the sum. We must then solve the equation $(1-p)\phi a + p\phi(a+b) = \phi x$, and x is the absolute sum corresponding to the present state of the party's expectation. Thus suppose the formula which expresses the value of x to be $k \log x + h$, and that a person who has now z must gain either $\alpha, \beta, \gamma, \dots$, of which the chances are $p, q, r, \dots$. The solution of

$$pk \log(z+\alpha) + ph + qk \log(z+\beta) + qh + \dots = k \log x + h$$

Theory of
Pro-
babilities.

Theory of
Pro-
babilities

gives $x = (z + \alpha)^p (z + \beta)^q (z + \gamma)^r \dots$ since $p + q + r + \dots = 1$,
and $(z + \alpha)^p (z + \beta)^q (z + \gamma)^r \dots - z$ is the benefit which the chances give.

(165.) If $\alpha, \beta, \gamma \dots$ be very small, the preceding is very nearly equal to $p\alpha + q\beta + r\gamma + \dots$, the expression for the mathematical expectation. That is to say, the absolute and relative methods may be considered as coincident for very small additions to the absolute sum proposed.

(166.) All risks, if only mathematically balanced, are disadvantageous. Suppose A, whose fund is a , stakes the sum μ , with the chance p of winning. He ought therefore to win $(1-p)\mu \div p$, and the value of his expectation is therefore

$$\left(a + \frac{1-p}{p}\mu\right)^p (a - \mu)^{1-p} - a, \text{ or } a \left\{ \left(1 + \frac{1-p}{p} \frac{\mu}{a}\right)^p \left(1 - \frac{\mu}{a}\right)^{1-p} - 1 \right\}.$$

The product in the second factor has the logarithm

$$p \log \left(1 + \frac{1-p}{p} \frac{\mu}{a}\right) + (1-p) \log \left(1 - \frac{\mu}{a}\right), \text{ or } (1-p) \int_0^{\mu} \left\{ \frac{p}{ap + (1-p)\mu} - \frac{p}{ap - p\mu} \right\} d\mu,$$

in which the coefficient of $d\mu$ is evidently negative for all positive values of μ . The logarithm is therefore negative, or the function less than unity: whence the expectation itself is negative.

To compensate the disadvantage, suppose t to be the sum against which μ is stated. Then

$$(a+t)^p (a-\mu)^{1-p} = a, \text{ or } t = \left\{ a^{\frac{1}{p}} \div (a-\mu)^{\frac{1-p}{p}} \right\} - a.$$

In the case where $p = \frac{1}{2}$ this is $\mu a \div (a - \mu)$. Thus a person should not stake half his fortune upon an even chance, unless the contingent gain is to be double of the stake.

(167.) In using the formula $k \log x + h$, to signify the moral value of a sum x , it is obvious that, though the initial supposition in (163.) may seem reasonable, the result deduced from it is of a strange and unusual appearance. But at the same time it may be shown that the results of common notions upon subjects which are unconnected with any principle of estimation of relative values, present an accordance with the consequences of the preceding method, which, even on the supposition of a mere accidental coincidence, shows that the formula itself, which exhibits such an agreement with conclusions drawn from other sources, must not be slightly thought of on account of its unusual form. Let us take the case of an insurance upon an event which must happen at some time or other, and may happen at any time, such as a common life assurance. In looking at the grounds of such a contract, we see that it is not gain which is contemplated, for the insured party is as likely to have over paid the value of his insurance as to have fallen short of it. Indeed, it is obvious that, if the insuring parties did not receive as much of surplus from those who live beyond the calculated term as they have to pay in the shape of loss to those who do not come up to the term, they could not fulfil their contracts. It is not, therefore, gain, but freedom from the consequences of uncertainty, which is the benefit contemplated by those who insure. It would have precisely the same effect if the uncertainty were removed by a power which could insure, not money in case of death, but actual life. We have before mentioned the tendency which exists to consider the average as the certainty which is to be assumed, when the effects of fluctuation or discordance are to be removed by assumption: and, in the present case, we are sure of being joined by a very large majority of those who would express any opinion on the subject, when we say that the practical effect of an insurance office must be, on the whole, to secure to each of its customers *his average life*: so that the moral effect of it would not be altered if each were made to live as long as, one with another, each does live. Without either adopting or rejecting this notion, let us remember that just as in (89.) the adoption of the method of averaging was found to be necessarily connected with the assumption of one particular law of facility of error, so in the present instance may the apparently fundamental proposition just stated be equally connected with some particular method of estimating the value of the contingent benefits of insurance. Now supposing a sum x to be paid at the end of n years from the present time, and v^n to be the present value of £1 due at that time, let $\phi(xv^n)$ be that function of the present value of x by which its value is to be estimated, as a possible payment of a contingent insurance. Upon the assumptions in (35.), the present value of an insurance of £1 is

$$(1 - P_1) \phi v + (P_1 - P_2) \phi v^2 + (P_2 - P_3) \phi v^3 + \dots \dots \dots (A).$$

Again, supposing s status to exist at first, the number left at the end of 1, 2, 3, &c. years (or other terms) is $sP_1, sP_2, sP_3, \&c.$, whence, provided that the duration of the different status through fractions of years may be neglected,* shows us that $s(1 - P_1)$ enjoy a complete year, $s(P_1 - P_2)$ enjoy two complete years, and so on: whence the average duration of each status is

$$(1 - P_1) + 2(P_1 - P_2) + 3(P_2 - P_3) + \dots \dots \dots = 1 + \Sigma P.$$

Insuring this duration, the present value of £1 at the end of the term, estimated according to the same formula, is $\phi(v^{1+\Sigma P})$. On equating this to the expression (A), the resulting functional equation is found to be satisfied by $\phi v = k \log v + h$. For in that case (A) becomes

$$(1 - P_1 + 2P_1 - 2P_2 + \dots) k \log v + (1 - P_1 + P_1 - P_2 + \dots) h,$$

or $(1 + \Sigma P) k \log v + h$. And this is the only solution which is equally true of any number of terms. On looking over the preceding, however, we remark that we have made the terms $v, v^2, v^3, \&c.$ enter the formula independently of any property which the insured possesses beyond his interest in the insurance. This is equivalent to supposing

* The common correction for this supposition amounts to adding half a year to the average duration.

Theory of
Pro-
babilities.

that his remaining interests, if any, are inconsiderable when compared with the insurance itself. Hence we see that, in the case of a person who depends entirely upon an insurance, the assumption that he is placed by the insurance office in precisely the position in which he would be if he were certain of living his average term, is not correct, unless accompanied by the supposition that the present moral value of every interest x is of the form $k \log x + h$, x being the mathematical present value.

Theory of
Pro-
babilities.

(168.) The principle of a common insurance is, as already observed, a moral security given to the insured, to whom his own particular case is every thing, in consideration of a mathematical advantage given to the insurers, who run no risk, seeing that they have the average of a large number of similar transactions. The amount which an insurer can afford to pay for the security, over and above its mathematical value, may be determined in a simple case, as follows. Let a man's property in hand, or otherwise certain, be denoted by 1, and let θ be the expected return of an existing venture, the chance of which turning out favourably is p . On the supposition that he does not insure, the relative value of his present expectation is $kp \log (1+\theta) + h$; but on the supposition that he insures, paying $(1-p)\theta + \alpha$, or the mathematical risk increased by an office profit α , he is then made certain of $1+p\theta - \alpha$, the relative value of which is $k \log (1+p\theta - \alpha) + h$. The equation of these two gives

$$\alpha = 1 + p\theta - (1+\theta)^p,$$

which is always a positive quantity, when θ is positive and p less than unity. For

$$p > p(1+\theta)^{p-1}, \text{ and } \int_0^\theta p d\theta > \int_0^\theta p(1+\theta)^{p-1} d\theta, \text{ or } p\theta > (1+\theta)^p - 1.$$

This value of α is the highest which can be prudently paid upon the hypothesis as to value which we are now considering. Let us suppose $\theta = \frac{1}{20}$, $p = \frac{49}{50}$, and we have $\alpha = .000025$, $(1-p)\theta$ being .001. That is, two and a half per cent on the mathematical value of the insurance is the greatest profit which should be allowed to the office.

In the case in which the risk p is not known, but it is equally likely to be of any values between, say p'' and p' , then the value of θ , resulting from the probability of success, is $\int_{p'}^{p''} \frac{dp}{p'' - p'} p\theta$, or $\frac{1}{2}(p' + p'')\theta$, so that the average risk may be taken.

(169.) Having thus made it appear that there is a method of estimating relative values more in accordance with the first notions on the subject than the assumption of absolute values, and which, in several cases, represents common opinion in its results, it becomes of interest to inquire how far this new hypothesis may be dispensed with in considering a multitude of transactions together. The truth is, as we shall proceed to show, that the division of risks not only diminishes the chances of fluctuation, as in (155.), but also tends to bring the relative value of a prospect near to its mathematical value: so that, though isolated transactions may frequently be looked upon with a degree of caution arising from the preceding considerations, yet there is no necessity to recommend the adoption of any new rule in calculations which involve multifarious dealings of a nearly similar kind.

Let us suppose the fraction θ in the last article to be invested in r similar risks, each risk having the probability p of turning out favourably. The chance of z being successful, and the rest otherwise, is therefore

$$\frac{[r, r-z+1]}{[z]} p^z (1-p)^{r-z}, \text{ and the result is } 1 + \frac{z}{r} \theta,$$

since $(z \div r)\theta$ is added by this event to 1 already possessed. Multiplying the relative value of each result by its probability, we find the following expression for the relative value of the prospect, the summation extending from $z=r$ to $z=0$, both inclusive,

$$\sum \left\{ \frac{[r, r-z+1]}{[z]} p^z (1-p)^{r-z} \left(k \log \left\{ 1 + \frac{z}{r} \theta \right\} + h \right) \right\};$$

which, as the logarithm independent of z , or made from $z=0$, vanishes, and the coefficient of h is $(p+1-p)^r$, becomes

$$kp \sum \int_0^\theta \frac{[r, r-z+1]}{[z]} \cdot \frac{p^{z-1}(1-p)^{r-z} z d\theta}{r+z\theta} + h \dots \dots (1);$$

but when the whole fraction θ is in one risk, the preceding integral becomes

$$kp \int_0^\theta \frac{d\theta}{1+\theta}, \text{ or } kp \sum \int_0^\theta \frac{[r-1, r-z+1]}{[z-1]} \frac{p^{z-1}(1-p)^{r-z} d\theta}{1+\theta},$$

since $(p+1-p)^{r-1} = 1$. Subtracting this from (1.), we have

$$kp \sum \int_0^\theta \frac{[r-1, r-z+1]}{[z-1]} \frac{p^{z-1}(1-p)^{r-z} (r-z) \theta d\theta}{(1+\theta)(r+z\theta)},$$

a quantity which is necessarily positive, since all its terms are positive. And this is the excess of the relative value of the divided risks over that of the single risk.

The expression (1) may be transposed into

$$kp \sum \int_0^\theta \frac{[r-1, r-z+1]}{[z-1]} \frac{p^{z-1}(1-p)^{r-z} d\theta}{1 + \frac{\theta}{r} + \frac{z-1}{r} \theta} + h,$$

Theory of
Pro-
babilities.which, as appears by the equation $\int_0^\infty e^{-cx} dx = \frac{1}{c}$, is

$$kp \int_0^\infty \int_0^\infty e^{-(1+\frac{\theta}{r})x} \{p e^{-\frac{\theta}{r}x} + 1 - p\}^{r-1} dx d\theta + h.$$

Let us first consider this expression with respect to x , that is, as $\int y dx$. There is no maximum or minimum of y between $x=0$ and $x=\infty$, for we have

$$\frac{dy}{dx} = -e^{-(1+\frac{\theta}{r})x} \left\{ p e^{-\frac{\theta}{r}x} + 1 - p \right\}^{r-2} \left\{ p(1+\theta) e^{-\frac{\theta}{r}x} + (1-p) \left(1 + \frac{\theta}{r} \right) \right\},$$

which is always negative between the limits specified. Proceeding as in (60.) we find

$$v = - \frac{p e^{-\frac{\theta}{r}x} + 1 - p}{p(1+\theta) e^{-\frac{\theta}{r}x} + (1-p) \left(1 + \frac{\theta}{r} \right)} \quad \frac{dv}{dx} = - \frac{p(1-p)(r-1)\theta^2 e^{-\frac{\theta}{r}x}}{r^2 \left\{ p(1+\theta) e^{-\frac{\theta}{r}x} + (1-p) \left(1 + \frac{\theta}{r} \right) \right\}^2}$$

Now y vanishes when $x=\infty$, and is $=1$ when $x=0$. In the latter case

$$v = - \frac{1}{1+p\theta + (1-p)\frac{\theta}{r}} \quad \frac{dv}{dx} = - \frac{p(1-p)(r-1)\theta^2}{r^2 \left\{ 1+p\theta + (1-p)\frac{\theta}{r} \right\}^2}$$

$$\int_0^\infty y dx = \frac{1}{1+p\theta + (1-p)\frac{\theta}{r}} \left\{ 1 + \frac{p(1-p)(r-1)\theta^2}{r^2 \left\{ 1+p\theta + (1-p)\frac{\theta}{r} \right\}^2} + \&c. \right\},$$

which is now to be integrated with respect to θ . But the expression, rejecting the higher powers of $\frac{1}{r}$, becomes

$$\frac{1}{1+p\theta} - \frac{1-p}{r} \frac{\theta}{(1+p\theta)^2} : \text{ and } kp \int_0^\infty \int_0^\infty y dx d\theta = k \log(1+p\theta) - kp \frac{(1-p)}{r} \int_0^\infty \frac{\theta d\theta}{(1+p\theta)^3}.$$

Adding h to both sides, it now appears that, when r is considerable, the absolute fortune corresponding to this result is nearly $1+p\theta$, that is, the sum already possessed together with the mathematical advantage of the prospect. At the same time the relative prospect is always a little less than the absolute one.

(170.) We shall now resume the problem in (40.), in which, as there shown, the mathematical advantage of the player is infinite. This will be a test of the practical value of the hypothesis now under consideration; since it is clear that no theory which professes to produce results in accordance with common notions, in cases where they are worth considering, ought to indicate that any one could prudently stake a large proportion of his fortune at such a game. Let a be the fortune at the outset, and x what the possessor should give for the chance of n throws; that is, his sole chance of gain is on the first time head is thrown, and if this happen at the v th throw, and v be less than or equal to n , he is to receive 2^v pounds sterling.

The relative value of his fortune before the stake is $k \log a + h$, after it $k \log(a-x) + h$, which there is the chance 2^{-n} that it will remain. At the same time there is the chance 2^{-v} that the absolute fortune will become $a-x+2^v$, and this for every value of v from $v=1$ to $v=n$. Hence the relative value of the prospect is

$$k \sum 2^{-v} \log(a-x+2^v) + h \sum 2^{-v} + 2^{-n} k \log(a-x) + 2^{-n} h,$$

or

$$k \sum 2^{-v} \log(a-x+2^v) + k 2^{-n} \log(a-x) + h,$$

or

$$\log \left\{ (a-x) \left(1 + \frac{2}{a-x} \right)^{\frac{1}{2}} \left(1 + \frac{4}{a-x} \right)^{\frac{1}{4}} \dots \left(1 + \frac{2^n}{a-x} \right)^{\frac{1}{2^n}} \right\} + h,$$

which, equated to $k \log a + h$, gives

$$a = (a-x) \left(1 + \frac{2}{a-x} \right)^{\frac{1}{2}} \left(1 + \frac{4}{a-x} \right)^{\frac{1}{4}} \dots \left(1 + \frac{2^n}{a-x} \right)^{\frac{1}{2^n}}.$$

These factors approximate without limit to unity: for the limit of

$$\frac{1}{2^n} \log \left(1 + \frac{2^n}{a-x} \right), \text{ or } \frac{n \log 2}{2^n} + \frac{1}{2^n} \log \left(\frac{1}{2^n} + \frac{1}{a-x} \right) \text{ is } = 0.$$

If these logarithms be summed, from $n=1$, until $2^n \div (a-x)$ is not small (say >10), the sum of the remainder of the logarithms *ad infinitum* from n inclusive, will be nearly

$$\sum \left(\frac{1}{2^n} \log \left(\frac{1}{a-x} \right) + \frac{a-x}{2^{2n}} + \frac{n \log 2}{2^n} \right), \text{ or } \frac{1}{2^{n-1}} \log \left(\frac{1}{a-x} \right) + \frac{a-x}{2^{2n-1}} + \frac{(n+1) \log 2}{2^{n-1}},$$

in which the tabular logarithms may be used, if the second term be multiplied by $\cdot 4342945$. We thus have, in the case where the mathematical advantage is infinite, the fortune which a person should have before the stake, in terms of his fortune after the stake, supposed given; that is, the proportion of his whole fortune which, on preceding principles, he may risk at this game. For $a-x=100$ it gives $a=108$, and for $a-x=200$ it gives $a=209$; that is, out of £108, not more than £8 should be risked, nor more than £9 out of £209.

(171.) All the problems which have hitherto been proposed are those in which an answer either can be given, or may be readily conceived to be given, to both of the questions proposed in (6.). We now proceed to a

Theory of
Pro-
babilities.

Theory of
Pro-
babilities.

class of investigations in which we are only concerned with the method of using the measures of probability, without being able to point out any practical mode of obtaining them. We refer to questions connected with evidence and matters of moral probability, in the usual sense of the words. But we shall begin by pointing out a mode in which the theory may be applied to a sort of intermediate question, which at first sight will appear utterly insoluble, but will nevertheless be shown to be perfectly within the theory (and, were it worth while, to a great extent within the practice) of the methods previously laid down.

Theory of
Pro-
babilities.

(172.) PROBLEM. A floor is ruled with equidistant parallel lines, and a thin rod of less length than the distance between two parallels is thrown down at hazard, and which therefore may or may not fall on one of the parallels, but cannot cut two of them: required the probability of its falling on one of the parallels.

Let a be the distance between the parallels, and $2r$ the length of the rod ($2r < a$). The problem will not be altered if we suppose that the centre of the rod must fall on one given perpendicular to the parallels, and also between two given parallels (inclusive): for in whatever proportion the number of favourable cases is increased by removing this restriction, the whole number of possible cases is increased in the same proportion. On the principle applied in (44.), let the distance a be divided into n equal parts, and a whole revolution into m equal parts, reckoning from the direction of one of the parallels. Let us suppose, for the present, that the centre of the rod must fall on one of the subdivisions of a , and that the angle its direction makes with that of the parallels must be a multiple of $2\pi \div m$. Then upon the supposition that its centre falls at a distance y from one parallel, the number of positions in which it can cut that parallel corresponds to the number of multiples of $2\pi \div m$, contained in the angle 4ϕ , where $r \cos \phi = y$ (it being possible that either side of the rod may cut the parallel), and is in the case of the limit proportional to 4ϕ ; that is, when m is increased without limit. Taking this result for all the subdivisions of a , we have, when n is increased without limit, the total number of favourable cases proportional

to $4 \int \phi dy$, or $4\phi y - 4 \int y d\phi$; that is, $4\phi y - 4r \sin \phi$, from $y=0$ and $\phi = \frac{\pi}{2}$ to $y=r$ and $\phi=0$; that is, $4r$. From $y=r$ to $y=a-r$ there are no favourable cases; while from $y=a-r$ to $y=a$ there are chances of the rod meeting the other parallel, which are, on the same suppositions, also represented by $4r$. Now the whole number of cases in each revolution are as 2π , and for all values of y , as $2\pi a$; whence $8r \div 2\pi a$, or $4r \div \pi a$ is the probability of the rod intersecting one of the parallels.

Hence, two out of the three, r , a , and π , being given, the third can be approximately found by observation of a large number of hazards. Thus an approximation to the value of the ratio between the circumference and diameter of a circle may be made by throwing a stick on a floor a sufficient number of times, and registering the number of times which the stick cuts one of the divisions between the boards. Supposing n throws to be made, and that $r \div a = \theta$, the probability that the number of throws in which this is the case lies between

$$\frac{4\theta}{\pi} n \pm \frac{2t}{\pi} \sqrt{2\theta(\pi - 4\theta)n} \text{ is (74.) } = \frac{1}{\sqrt{\pi}} \int_{-t}^{+t} e^{-t^2} dt.$$

To make the probable variation the least fraction of the whole, *cæteris paribus*, $(\pi - 4\theta) \div \theta$ must have the least value* consistent with $\theta < \frac{1}{2}$, or $= \frac{1}{2}$, which will admit of the application of the process. Hence we must take $\theta = \frac{1}{2}$, or the rod must be equal in length to the distance between the parallels. In this case m out of n being the observed number of times which the rod strikes one of the parallels, the probability that m lies between

$$\frac{2n}{\pi} \pm \frac{2\sqrt{(\pi - 2)n}}{\pi} \cdot t \text{ is } \frac{1}{\sqrt{\pi}} \int_{-t}^{+t} e^{-t^2} dt.$$

In this way it is sufficiently obvious that, were such a process necessary, the value of π might be determined with any degree of accuracy short of that with which lines can be actually measured. And many problems might be suggested in which the determination of given constants by comparison of the results of large numbers of hazards, strange as it may appear at first sight, is free from any difficulty of principle.

(173.) We now consider a class of questions in which we can only form a notion of the method of using data, without absolute knowledge of what the data may be in any particular case. We refer to the probabilities of evidence, and of judicial or other decisions, considered as depending upon the separate probabilities of each witness, or of each judge. It would much facilitate a proper use of the theory, if its particular province in these matters were better defined than is usual in mathematical writings.

All application of the present subject requires firstly, that we should not be in possession of any absolute cause from which we can deduce the quantity or character of an effect; and secondly, that there should be (4.) some relation between the successive phenomena in question, which makes us certain that, happen what may, there is some particular reason for the event being what it is and no other. The observation of physical phenomena shows us that one circumstance, which call A, is either always accompanied by another, B, in which case the connection between the two is the object of mathematico-physical research; or else it shows that A is more or less frequently followed by B. In the latter case, the phenomena having reference to quantity, we do not stop here and consider the connection between A and B as more or less probable: for our means of further inquiry may be such as to enable us to seek an absolute reason why B should follow in some cases, and not in others; that is, to detect all the relations of cause and effect which exist among the various particular phenomena which

* The result of Laplace (p. 360) makes the fluctuation for which there is a given probability a *maximum* instead of a *minimum*.

Theory of
Pro-
babilities.

were examined. But the boundary between absolute knowledge and absolute ignorance is not a mathematical line: there is an intermediate state in which our partial knowledge of relations, and means of observation, oblige us to consider results as having more or less probability, which we do not therefore imagine to be themselves fortuitous or unfixed. It is precisely the same with most of the questions on which neither the certainty of physical measurement nor of mathematical deduction can be obtained: the only difference lies in the very different character of the means of discovery which it is necessary to employ.

Theory of
Pro-
babilities.

Accurate investigation, or absolute physical or mathematical demonstration, being supposed impossible, it might be imagined that the next method of inquiry, in order of merit, would be the absolute collection and comparison of large numbers of facts. Such a process would lead direct to the application of the theory of probabilities: and the little use which has been made of the latter arises from the neglect to procure the former. All attempts of this kind have been of comparatively recent date. It seems to have been one of the most difficult conceptions which could be arrived at, that by possibility there might exist general laws among masses of phenomena, however uncertain might be the results of any particular case. Take two men aged forty, and it is very possible that the life of one of them should be double that of the other; but it is extremely improbable, and is never found to be the fact, that the sum of the lives of one hundred men, each aged forty, differs materially from the same sum for another hundred lives of the same class. Statistical observations are making it more clear from day to day, that, taking a whole community, there is hardly any one circumstance which admits of measurement, in which the average of one year differs greatly from that of another, or in which a gradual progression in either direction exists without a sufficient and assignable cause.

(174.) This power of deriving knowledge from numerical observation of facts, which exists incontestably with regard to natural and social phenomena, is denied by many in regard to questions the elements of which are functions of the moral and intellectual state of mankind. Independently of the theoretical, we see also a practical denial of such power, in the indisposition to collect any specific information. Perhaps no question of its kind has been more debated, than the English policy of requiring absolute unanimity among the individuals composing a jury. The *tendency* arguments, the *à priori* deductions of reason for or against, from the nature of man, and the "state of society," the discussion of the "principle" of starvation, &c., &c., &c. are very amusing drawing-room topics, and will, we doubt not, with many, supersede the necessity of counting cases. But for ourselves we should feel much better able to form an opinion if we could procure some statistical knowledge of this kind. All the world knows that when a jury retires for two or more hours, the necessity for an unanimous verdict is the proximate cause, in nine cases out of ten at least. Now presuming, which we doubt not is the fact, that in most cases where new trials are granted there is some reason which people in general would be inclined to admit for disturbing the previous verdict, a test presents itself which must be acknowledged to be very likely to afford a valuable result. Take five hundred trials, in which the jury have delivered their verdict at once, and five hundred more in which they have deliberated for two hours. Does the per-centage of new trials granted from the conduct of the jury in the second set exceed that in the first set? No doubt it does would be the answer; for the second five hundred would include all the difficult cases. But, not allowing any thing to these antecedent presumptions, we should like to be informed *as to the fact*. In the first set there is real unanimity; in the second there is the forced unanimity of the law. If it should turn out (and no one knows the contrary, for it has never been tried) that the per-centage of error in the second set does not materially exceed that in the first, there arises an argument for the continuance of the present system by very much stronger than any which has been produced. But better still, such information might arise during the process of examination, as would show in what direction further inquiries should be made.

(175.) But though the preceding process have one definite practical end, the consequences fairly deducible from it may be carried further. Suppose it to be established from the first set of cases, that unbiassed unanimity, where it occurs, is liable to a certain chance of error. The questions next arise, what chance of error is thence to be attributed to each individual of the twelve? Would the chances of error be materially altered if the number of the jury were reduced to six? Such questions as these are mathematical deductions, and can be clearly shown to be such. Let us suppose, for instance, that we put the following case. Knowing the absolute impossibility of judging with certainty from such evidence as it is generally practicable to procure, we must rest with the conviction that a certain proportion of judicial decisions (let us confine ourselves to criminal cases, where the verdict can be only one out of two) will be wrong. Let us admit that society is secure if only one decision out of a hundred be

wrong; that is, if the probability of a correct decision be $\frac{99}{100}$. Let us further admit, which seems reasonable,

that, owing to the manner in which unanimity is obtained in our courts, the verdict of a jury of twelve men is not entitled to more confidence than would be a majority of eight to four, all unbiassed by each other, and each worthy of the average degree of confidence. It then becomes a purely mathematical question what that average degree

of confidence should be, in order that the aforesaid majority may invest its decision with a probability of $\frac{99}{100}$.

(176.) Let x be the probability that any one individual will form a right decision. Then the observed event being, that eight are of one opinion and four of another, two cases arise which may be considered as causes: 1. That the majority is right and the minority wrong, which gives $x^8(1-x)^4$ for the probability of the observed event. 2. That the minority is right, which gives $(1-x)^8x^4$ for the same probability. Hence the probability that the decision is correct is

$$\frac{x^8(1-x)^4}{x^8(1-x)^4 + (1-x)^8x^4}, \text{ which in (175.) is supposed } = \frac{99}{100}; \text{ giving } x = \frac{1000}{1317}.$$

Theory of
Pro-
babilities.

This problem will serve to illustrate the particular province of our theory in regard to such a question. No mathematician, as such, can say whether or no the confidence due to the verdict of an English jury is or is not equivalent to an unbiassed majority of eight over four: nor can he undertake, as such, to say, whether one wrong verdict out of a hundred is within or without the limits of necessary security. But he *can* undertake to say that, upon the preceding suppositions, the preceding amount of security cannot be attained, unless the individual jurymen, supposed equally worthy of confidence, be such as can be depended upon for correctly deciding about ten cases out of thirteen, each one by himself.

Theory of
Pro-
babilities.

This individual probability of correctness being admitted, the reduction of the jury to six, and the requirement of unanimity, considered as equivalent in value to the verdict of four against two, would give for the probability of the verdict

$$\frac{x^4(1-x)^2}{x^4(1-x)^2 + x^2(1-x)^4}, \text{ which when } x = \frac{1000}{1317} \text{ is } = \frac{10}{11} \text{ nearly:}$$

or such a jury would decide one case out of eleven wrongly.

(177.) The same distinctions may be drawn with regard to the value of evidence, and they tend to separate the worth of an hypothesis, which may be small, from that of the conclusions drawn from it, which may be absolutely demonstrable. For instance, there are very few cases in which different witnesses who actually assert the same fact are perfectly independent of each other, so that neither could have known of the existence of the other's evidence. In such cases we give immediate credence to the account. But it more usually happens that there is mixed up with the consideration of the question, 1. a possibility of collusion between the witnesses; 2. the circumstance of the evidence of all not being the same, but exhibiting only more or less of agreement. These two characteristics of evidence are in some degree contradictory of each other; perfect agreement strengthens the probability of collusion; * while to draw the line, and determine where disagreement ceases to be presumption of honesty, and to become that of perjury, is the most delicate part of a decision. Taking all such circumstances into account, it becomes impossible even to frame a mathematical hypothesis, the results of which it would be worth while to examine. Nevertheless there are circumstances connected with the mathematical theory of independent evidence which it may be useful to examine.

In this, as in several other preceding investigations, it is not so much our wish to deduce and *impose* results, as to inquire whether these results really coincide with the methods of judging which our reason, unassisted by exact comparison, has already made us adopt. The use of the process is, that both our theory and our preconceptions thus either assist or destroy each other: in the former case we feel able to trust this science for *further directions*; in the latter, a useful new inquiry is opened. For when we consider the very imposing character of the first principles of the science of probabilities, and the mathematical necessity which connects those simple first principles with their results, we feel convinced that, even on the supposition that the main conclusions of the present treatise are altogether fallacious, there must arise a necessity for investigating the reason why a *methodical* treatment of certain notions should lead to results inconsistent with the *vague* application of them on which we are accustomed to rely. For it must not be imagined that opposition to the principles laid down in this treatise is always conducted on other principles: on the contrary, it frequently happens that it is only a result of themselves obtained without calculation, which is arrayed against arithmetical deduction.

(178.) A witness, whose *veracity* (meaning here the probability that he is willing to speak truth) is p , and whose judgment (meaning the probability that he is correct in what he supposes) is r , asserts a circumstance to have happened. Say that there is a lottery with n balls, and he asserts number *one* to have been drawn, it being known that some one or other has been drawn. Required the probability that number *one* actually was drawn. There are two cases in which number one was drawn: 1. The witness tells† the truth, and is correct in his idea of it. 2. The witness intends to deceive, and to state a number which was not drawn, but mistakes the number drawn, and selects the real one, thinking it not to be such. The probability of the first supposition is pr : that of the second depends on three circumstances, namely, that he intends to deceive, is wrong in his judgment, and chooses number *one* out of $n-1$ balls which might equally have been chosen. Of this triple event the probability is $(1-p)(1-r) \div (n-1)$, and therefore the probability that the event stated really happened is

$pr + \frac{(1-p)(1-r)}{n-1}$. If the possible number of events be very great, then pr is the probability in question; but if there be only two, then $1 + 2pr - p - r$ is the probability.

(179.) The preceding question is solved in a different manner by Laplace, as follows. Here is an observed event, namely, the *announcement* of the drawing of number one, and the actual truth of the statement is one among the various causes (or precedent circumstances) of the observed event. The hypotheses which can be made as to the preceding circumstances are as follows: 1. The witness is both honest and correct. 2. He is dishonest, but not mistaken. 3. He is honest, but mistaken. 4. He is both dishonest and mistaken. In either case he may announce number one: and the probability of this event being determined from each hypothesis, the sum of such probabilities as necessarily involve the truth of the fact, divided by the sum of all the probabilities, will

* Cases may arise in which disagreement happens by collusion; but the whole history of judicial evidence tends to show that cross-examination must render not only the disagreement, but the agreement, of collusion, almost certain to be detected. At the same time, such detection may become difficult, if the circumstance on which the deception turns be extremely simple. There was, it is said, at one time an Old Bailey method of proving an *alibi*, which often succeeded. The parties called for the prisoners swore honestly to an *alibi* which really existed some hours or days before the committal of the offence, taking care to state no untruth whatsoever, except only the *time* of the circumstances to which they deposed.

† Observe that this phrase has throughout reference to his intentions: he means to tell the truth.

Theory of Probabilities. give the probability that the precedent circumstances are one or other of the sets which involve the truth of the fact; that is, that the announcement is true. Theory of Probabilities.

Now in the principle of (19.), it is easily shown that, if the causes be not *a priori* equally probable, the probability which each cause gives to the observed event must be multiplied by the probability of the cause itself. If, for instance, a white ball be drawn from one or other of two lotteries, which have the fractions a and b of white balls out of the whole of each, the probability of the first lottery having been the one selected is $a \div (a+b)$. But if there be m of the first lotteries, and n of the second, then though the probability of any one of the first lotteries having been chosen is $a \div (ma+nb)$, yet that of one or other of the first having been chosen is

$$\frac{ma}{ma+nb}, \text{ or } \frac{\{m \div (m+n)\} a}{\{m \div (m+n)\} a + \{n \div (m+n)\} b}, \text{ as was asserted.}$$

Reasoning in this way, we give the results of the four several cases mentioned above, as exercises in the subject:

$$(1.) \frac{pr}{n}, \quad (2.) \frac{n-1}{n} \cdot \frac{1}{n-1} (1-p)r \quad (3.) \frac{n-1}{n} \frac{1}{n-1} p(1-r) \quad (4.) \frac{n-2}{n(n-1)} (1-p)(1-r) + \frac{1}{n(n-1)} (1-p)(1-r).$$

In the fourth case the first term has reference to the case where number one is not drawn; and the second to that in which number one is drawn. And the sum of the probabilities corresponding to the truth of the announcement, $pr \div n + (1-p)(1-r) \div n(n-1)$, divided by the sum of all (which is $1 \div n$), gives the result of the preceding article.

(180.) Let α and β be the probabilities of a white and black ball ($\alpha + \beta = 1$): and a witness has announced a white ball; his veracity and judgment being as before. On the first hypothesis of the preceding article (of which the chance is pr) the white ball must have appeared, and the relative probability of this hypothesis is αpr . On the second hypothesis, the same is $\beta(1-p)r$; on the third $\beta(1-r)p$; and on the fourth $\alpha(1-r)(1-p)$; for this case can only happen when the announcement is true (there being but two possible cases). Hence $\{q = pr + (1-p)(1-r)\}$.

The probability that an event whose chance is α , asserted by a witness whose veracity is p and judgment r , really did happen is $\frac{\alpha q}{\alpha q + (1-\alpha)(1-q)}$.

This is in accordance, as to result, with the universal impression that a very extraordinary event, asserted by a single witness, is not worthy of belief unless the presumptions in favour of the honesty of the witness be proportionally strong. It must be observed, that q is the probability that the witness states what happened (whether by intention or by mistaken method of attempting to deceive), without reference to the probability of the event. And the preceding probability becomes an even chance when $q + \alpha = 1$: that is, we may by easily admissible conventions make the following sentence a mathematical truth. An extraordinary fact, *asserted by one witness*, becomes as likely as not, if the character of the witness for honesty and judgment together be such that his being incorrect would be as extraordinary as the fact itself.

It is here worth while to notice the preceding result as a specimen of the manner in which a mathematical expression points out the most convenient meaning of a term. Thus in the Article LIGHT, the inverse of the focal length of a lens is called its power; not because there are any *a priori* notions which point out the propriety of such a definition, but because it appears that, subsequently to the deduction of a complicated proposition, such a definition will lead to the *desirable* theorem, "the power of a complex lens is the sum of the powers of the simple lenses;" a notion which any one would be likely to form, but which could not be formed correctly unless the definition of power were as above stated.

It is not of unfrequent occurrence that such a choice is made of the meanings to be assigned to terms as will render a common and vague notion strictly true. Thus it is universally admitted that the extraordinary nature of an asserted event must be overcome by evidence of such strength that its failure would be at least as extraordinary as the fact. This proposition becomes a mathematical truth under the following definition. The *strength* of the evidence of a single witness is measured by $pr + (1-p)(1-r)$, where p measures his veracity, and r the correctness of his judgment. We shall resume this point after having considered the evidence of two or more witnesses who agree in asserting the same thing.

(181.) Let a number of ν witnesses, whose veracities are p_1, p_2 , &c., unite in asserting that number one was drawn out of a lottery containing n different numbers. Let it also be supposed, for simplicity, that they are not liable to mistake: whence it follows either that all tell the truth, or that all deceive; the probabilities of which hypotheses are $p_1 p_2 \dots$ and $(1-p_1)(1-p_2) \dots$. In the first case, number one was drawn, of which the probability is $1 \div n$: in the second all the witnesses have separately chosen the same false number, of which, supposing them to have no bias in favour of one rather than another, the probability is $1 \div n(n-1)^{\nu-1}$, where ν is the number of witnesses; for $(n-1) \div n$ is the probability that number one is not drawn, and $1 \div (n-1)^{\nu}$ is the chance of ν individuals fixing on the same number out of $n-1$. Hence, as in the preceding articles, the probability which the evidence gives to the fact asserted is

$$\frac{(n-1)^{\nu-1} p_1 p_2 p_3 \dots}{(n-1)^{\nu-1} p_1 p_2 p_3 \dots + (1-p_1)(1-p_2)(1-p_3) \dots}$$

From this we see* the necessity of distinguishing between the case in which there are only two events to choose out of, and that in which there are three or more. If a hundred witnesses of very bad character (say of a veracity of one-tenth) unite in asserting that A happened where only A or B could happen, the multiplication of

* By which we mean that we see such a consequence to result from the mathematical formula. We are not proving these well-known things, but simply showing that the results of the formula coincide with those which are universally admitted.

Theory of
Pro-
babilities.

evidence weakens the probability of the fact, which is only $1 \div (1 + 9^{100})$. Here the only question is, Have these witnesses all spoken truth, or all spoken false? and it is clear that though the union be an extraordinary fact, yet it is much less extraordinary on the second supposition than on the first. But if there had been ten possible cases, A, B, C . . . the question is, Have these witnesses all spoken truth, or have they all, not only spoken false, but independently fixed upon A as the false assertion out of nine equally probable ones? The probability of the assertion now becomes $9^{99} \div (9^{99} + 9^{100})$, or one-tenth. But it is evident that, however low the veracity of the witnesses may be, the number of events out of which they have to choose may be so great that (collusion being impossible) the truth of an unanimous assertion becomes insuperably probable. The result is, that in cases where a very large number of different events might have been chosen, the unanimity of many witnesses (or even of two witnesses) entirely destroys all question about their veracity, and throws the whole difficulty of deciding upon this question, Was there, or was there not, collusion? Whether they be good or bad witnesses individually can only affect the rational probability of their assertion in the manner in which it affects our disposition to suspect combination. And here are two distinct elements to be employed: firstly, what, all circumstances considered, is the probability that there *could have been* collusion? secondly, what, from the known character of the witnesses, is the probability that there *was* collusion?

(182.) We have said that the mere unanimity of witnesses upon an assertion chosen out of a very large number, throws their veracity out of the question, until we come to ask whether there was or was not collusion. There is a celebrated argument with regard to miracles (that of Hume), of which it may be said that it was a fallacy answered by fallacies, so far as the mathematical bearing of it was concerned. Many who reject the mathematical theory of probabilities nevertheless read Hume's argument and Paley's answer with serious attention, never dreaming that they are considering a mathematical formula expressed in words, and that $q + \alpha = 1$ (see (180.)) contains Hume's assertion, tacitly admitted by Paley.

Hume, (*Essay on Miracles.*)

When *any one* tells me that he saw a dead man restored to life, I immediately consider with myself whether it be more probable that this person should either deceive or be deceived, or that the fact which he relates should really have happened. I weigh the one miracle against the other, and according to the superiority which I discover, I pronounce my decision, and always reject the greater miracle. If the falsehood of his testimony would be more miraculous than the event which he relates; then, and not till then, can he pretend to command my belief or opinion.

Paley, (*Evidences of Christianity.*)

Mr. Hume states the case of miracles to be a contest of opposite improbabilities, that is to say, a question whether it be more improbable that the miracle should be true, or the testimony false: and this I think a fair account of the controversy.

Now from the preceding articles it appears, 1. That not only is Hume's principle rational *in the case of a single witness*, but that he himself would have been (had he understood his own assertion) of a morbid degree of faith, willing to believe a miracle the moment more than an even chance was made out in its favour. 2. That in the case of *two or more witnesses*, his "contest of opposite improbabilities" fails entirely to represent the state of the case, and should not have been admitted as "a fair account of the controversy."

(183.) Generally speaking, however, the favourable presumptions which evidence presents do not arise from the selection by several witnesses of the same circumstance out of many, but from their agreement in several circumstances, each of which presents only a pair of alternatives. And it may be fairly assumed that, before an assertion is made, that is, before the nature of the fact asserted affects the character of the witness, it is more likely than not that the witness will speak the truth. Let us assume that all degrees of veracity between $\frac{1}{2}$ and 1 have equal presumptions. It is observed, that n witnesses have all agreed in asserting m distinct facts, of each of which the antecedent probability is α , (let $\alpha + \beta = 1$). Required the probability that all these facts shall be true.

The veracity of a witness being x , the probability of n witnesses agreeing in the assertion of any one of the facts is the sum of the chances in the two following cases: 1. The fact happens, and all the witnesses speak truth. 2. The fact did not happen, and all the witnesses speak falsely. This probability is, therefore, $\alpha x^n + \beta (1 - x)^n = P$. Consequently the probability of m such occurrences is P^m , and the presumption which the observed event gives to any value of x is $P^m dx$, divided by $\int P^m dx$, taken between the widest limits of the question, that is, from *one half* to *one*.

Hence the presumption for any value of x between one half and one is $P^m dx \div \int_{\frac{1}{2}}^1 P^m dx$. Again, a value of x being assumed, the resulting probability of the several facts being all true is $(\alpha x^n \div P)^m$; whence it follows that the probability of x having a given value, and of the facts being true, is

$$\frac{P^m dx}{\int_{\frac{1}{2}}^1 P^m dx} \times \frac{\alpha^n x^{mn}}{P^m}, \text{ or } \frac{\alpha^n \int_{\frac{1}{2}}^1 x^{mn} dx}{\int_{\frac{1}{2}}^1 P^m dx} \text{ is the total probability.}$$

The same process may be applied to the case in which out of n witnesses ($= p + q$) p unite in affirming and q in denying m different facts.

(184.) We shall notice one more case, taking the same sort of definite mathematical assumption which has already preceded. *Tradition*, in the strictest sense, is the delivery of a statement by a first witness to a second, by the second to a third, and so on, no one witness having any authority except that which he derives from the

Theory of
Pro-
babilities.

Theory of
Pro-
babilities.

Theory of
Pro-
babilities.

one immediately preceding. In the more common signification of the term, it implies the successive delivery of a fact from generation to generation, each race having not only the authority of that immediately preceding, but also the confirmation of written or other monuments: to such an extent, that the only pure *tradition* is that of the writings, customs, or other modes of testimony.

Suppose that any number of successive witnesses pass the statement that, out of a lottery of n balls, number *one* was drawn; that is, the observed event is, that the r th witness affirms that he was told this by his predecessor. Let the veracity of the r th witness be p_r , and let y_r be the probability of the fact so soon as stated by this witness. Then, on the delivery of the statement to a new witness (the $(r+1)$ th), the probability of the fact (y_{r+1}) is the sum of the two following probabilities. 1. That the r th witness is correct, and the $(r+1)$ th reports him truly, (or $p_{r+1} y_r$). 2. That the r th witness is incorrect, and that the $(r+1)$ th witness reports his account falsely, choosing number one out of $n-1$, not named by the predecessor, (or $(1-p_{r+1})(1-y_r) \div (n-1)$). Hence we have

$$y_{r+1} = p_{r+1} y_r + \frac{(1-p_{r+1})(1-y_r)}{n-1} = \frac{(np_{r+1}-1)y_r + 1 - p_{r+1}}{n-1},$$

or

$$y_{r+1} - \frac{1}{n} = \frac{np_{r+1}-1}{n-1} \left(y_r - \frac{1}{n} \right),$$

whence

$$y_r = \frac{1}{n} + \frac{n-1}{n} \cdot \frac{(np_1-1)(np_2-1)\dots(np_r-1)}{(n-1)^r},$$

where the constant of integration $(n-1) \div n$ is so taken that when $r=1$ $y_1=p_1$. From this it appears, that so long as the veracity of the witnesses is greater than the probability of the fact, their evidence makes the latter more probable than it is in itself. But a single witness less credible than the fact itself makes the whole chain of evidence weaken the intrinsic probability, and so does the occurrence of any *odd* number of such witnesses; while an *even* number of the same has the contrary effect. The mathematical treatment of this problem serves to show how little the common notion of tradition coincides with the strict definition of it. That no received fact of history is really accompanied by a distinct perception and admission of its having passed through many successive witnesses, will be readily admitted: and we may add, looking at the manner in which the general results of the theory of probabilities coincide with maxims to which universal assent is given, that disagreement between any mathematical result and general opinion is of itself a strong presumption that the first principles on which the former is obtained are not those on which the latter is formed. Thus we see that, in the result of the preceding investigation, a succession of witnesses of no credibility whatsoever (or who always speak false), if *even* in number, increases the intrinsic probability of the fact delivered by the last.

If the number n be extremely great, the result of the preceding is very nearly the product $p_1 p_2 p_3 \dots p_r$.

On the preceding investigation, the same observations may be made which have suggested themselves with regard to the evidence of a single witness. When there is only one chain of tradition, the evidence for the fact asserted depends materially on the character of the witnesses. But when there are two or more such chains, which end by agreeing in one fact, out of a great many which might have been chosen, the character of the witnesses becomes immaterial, except so far as it affects the chances of previous collusion. If it be impossible that there can have been concerted agreement between any of the witnesses in the two chains, then their final agreement is insuperable evidence of the truth of the fact which they assert: including under the case of concerted agreement, that in which the separation of the two chains is not entire throughout their whole continuance, or in which the same witness or witnesses are part of both chains.

(185.) We feel at liberty to say, that though a result of the theory of probabilities, upon a moral question, is not to be lightly or easily adopted, when it differs from usual notions, yet on the other hand it is not therefore to be immediately rejected. When both the ordinary notion and the mathematical result are derived from the same hypothesis, the latter must be the more correct: and in those numerous cases in which the difficulty lies in reducing the original circumstances to a mathematical form, there is nothing to show that we are less liable to error in deducing a common sense result from principles too indefinite for calculation, than we should be in attempting to define more closely, and to apply numerical reasoning.

(186.) *Remark on Article (88.)*—The theory of series, in the case of terms which are alternately positive and negative, receives an important addition from the theorem given by Lagrange on the limits of Maclaurin's theorem; namely,

$$f(x) = f(0) + f'(0) \cdot x + f''(0) \frac{x^2}{2} + \dots + f^{(n)}(0) \frac{x^n}{2 \cdot 3 \dots n} + f^{(n+1)}(\theta x) \frac{x^{n+1}}{2 \cdot 3 \dots (n+1)},$$

where θ is less than unity. It is easily proved that, in the case of *decreasing* terms *ad infinitum*, alternately positive and negative, the sum of any number of terms is in error by less than the first term rejected; and this whether the whole number of terms be finite or infinite. Whence it follows, that if such a series as $A - Bx + Cx^2 - \dots$ begin by diminishing terms, the same proposition is true as long as the terms diminish, even though they should afterwards increase without limit. Supposing we stop at the term $f^{(n)}(0) \times x^n \div 2 \cdot 3 \dots n$, all the terms up to that point having been as above described, the theorem stated must be true for all values of x which make $f^{(n)}(0)$ greater than $f^{(n+1)}(\theta x) \times x \div (n+1)$, provided $f^{(n+1)}(\theta x)$ be always of a contrary sign to $f^{(n)}$ from 0 to x . Thus, in the third series of (62.) for $\int \varepsilon^{-t^2} dt$, we see a series which though always divergent at last, yet begins by convergency whenever $2a^2$ is greater than 1. Thus when $a=2$, we may infer that

$$\int_0^\infty \varepsilon^{-t^2} dt \text{ does not differ from } \frac{\varepsilon - a^2}{2a} \left(1 - \frac{1}{2a^2} \right) \text{ by so much as } \frac{1 \cdot 3 \varepsilon - a^2}{8a^5}.$$

INDEX TO THEORY OF PROBABILITIES.

Index.

(1—42.) *Principles of the subject: sketch of methods, and solution of simple questions.*

- (1.), (2.) Object of mathematics in the theory of probabilities.
- (3.) Meaning of the word probability.
- (4.) Distinction between *chance* and *probability*.
- (5.) Homogeneity of the notion of probability arising out of different kinds of events.
- (6.) Distinction between the psychological and mathematical part of the subject.
- (7.) Method of arriving at the measure of probability.
- (8.) Definitions connected with the measure of probability.
- (9.) Simple application for practice.
- (10.) Theorems on combinations connected with the subject.
- (11.) Principle on which algebraical developement distributes the whole number of the possible events into the several numbers of different cases.
- (12.) *Principle I.* Definition of probability.
- (13.) *Principle II.* Probability of compound events determined.
- (14.) *Principle III.* Method of (12.) extended to the case where the simple probabilities are not the same.
- (15.) Probability of a conclusion deduced from that of the premises.
- (16.) Action of the probability deduced from one argument upon the premises of another. Objection to the method followed by writers on logic.
- (17.) Consideration of D'Alembert's objection.
- (18.) *Principle IV.* Converse operation to that in (13.).
- (19.) *Principle V.* Probability of an antecedent determined from the observed consequent.
- (20.) *Principle VI.* Deduction of the probability of an event to come from an observed event.
- (21.) Definition of gambling. (22.) How avoided by division of risks.
- (23.) Discussion of *runs of luck*.
- (24.) On the notion that the change of an indifferent circumstance changes luck.
- (25.) Mistake arising from confounding an event past with one to come.
- (26.) *Principle VII.* On the value of a contingent gain.
- (27.) Application of the preceding to cases of many risks.
- (28.) Remarks on the application of the preceding in commerce.
- (29.), (30.), (31.) A gambling trick. On gambling in general.
- (32.) Statement of different cases of life contingencies.
- (33.) Problem of life annuities.
- (34.) Problem of deferred life annuities.
- (35.) Present value of a reversion or an insurance.
- (36.) Premium to be paid for the last.
- (37.) Instance of the more complicated problems of life contingencies.
- (38.) Moral expectation as distinguished from mathematical.
- (39.) *Principle VIII.* Relative stakes necessary for fair play.
- (40.) Paradox connected with the mathematical expectation.
- (41.) *Principle IX.* Insufficiency of the mathematical expectation.
- (42.) Plausible substitute for the latter.
- (43.—54.) *Complicated problems solved without the aid of the integral calculus.*
- (43.) Simple problem solved independently, and also by the method in (11.)
- (44.) Probability of the amount of the sum of the drawings in a lottery.
- (45.) Extension of the last to the case of an infinite number of possible drawings.
- (46.) Application to a point connected with the theory of the solar system.
- (47.) Extension of (14.) by the integral calculus.
- (48.) On the probable contents of a lottery, as inferred from drawings, the possible cases being given.
- (49.) The same where the number of possible cases is unlimited. Occurrence of the difficulty mentioned in (15.)
- (50.) Chances of two players, each of whom wants a given number of points. General principles of the theory of generating functions, and of the interpolation of series.

Index.

- (51.) Method of solving an equation of differences by generating functions.
- (52.) Chance of one player beating n others in succession in less than x trials.
- (53.) Problem of the chance of *runs of luck*, the skill of the players being different.
- (54.) Probability of all the numbers in a lottery coming out in n trials.
- (55.—83.) *Method of applying the calculus of definite integrals to the valuation of functions of high numbers.*
- (55.) Remarks on functions which contain a variable number of factors.
- (56.) Sketch of the method of expressing such functions by a definite integral.
- (57.) Application to the cases of rational functions. Expression of their differential coefficients and differences.
- (58.) Case of s^{-1} and $\Delta^n.s^{-1}$.
- (59.) Investigation of a function of y which is necessarily small, when n contains many factors.
- (60.) Expansion of $\int y dx$ in powers of the functions of (59.)
- (61.) Way in which great exponents make convergent series.
- (62.) Expansion of $\int y dx$ in the case where one of the limits makes y a maximum. Investigation of the integrals on which the result depends. Methods of determining $\int \epsilon^{-t} dt$ from $t=0$.
- (63.) Conversion of the last integral into a continued fraction.
- (64.) Extensions of the process of definite integration in (62.)
- (65.) Determination of $\int y dx$, where y contains many factors, between two values of x , which make $y=0$.
- (66.) Another method. (67.) Determination of the indeterminate coefficients.
- (68.) Application to integrals of the form $\int y dx dx'$.
- (69.) Developement of the result of (62.) for any limits, and investigation of the convergency of the result.
- (70.) Application to the case of $1.2.3\dots s$.
- (71.) Deduction of the preceding from the common developement of Σy .
- (72.) Proof of the nearness of the approximation.
- (73.) Application to $1.3.5\dots(2s-1)$.
- (74.) Probability of a given amount of fluctuation on a large number of similar events whose probabilities are given. Example.
- (75.) Change of the form of the preceding result. Remarks on contingency offices.
- (76.) The probable limits of fluctuation vary as the square root of the number of events.
- (77.) Inverse problem to that in (74.)
- (78.) Various integrals deduced from (62.)
- (80.), (81.) Remarks on definite integrals.
- (82.), (83.) Coefficient and sum of the coefficients between given limits, of the s th power of Σa^n , determined.
- (84.)—(138.) *Application of the theory to the estimation of the probable result of discordant observations.*
- (84.) Conditions under which discrepancy is called error.
- (85.) The observer and the instrument the united source of error.
- (86.) Definition of the *law of facility*.
- (87.) Estimation of the *disadvantage* of an error.
- (88.) *A priori* conditions which the law of facility must fulfil.
- (89.) The average not *theoretically* the most probable result for all laws of facility. Determination of the law under which it is so.
- (90.) Reason why the average is *practically* a sufficient approximation.
- ** From (91.) to (98.) the law of facility deduced in (89.) is adopted.
- (91.) Probability that the error of an average lies between given limits, determined.
- (92.) Comparison of the errors of the averages of different sets.

Index.

- (93.) Bad observations in large numbers not preferable to few and good ones.
- (94.) Example of the determination of the constant of the law of facility.
- (95.) Problem of (91.), the observations having different laws of facility. Definition of the term *specific weight*.
- (96.) Definition and expression of the *risk* or *mean risk* (*l'erreur moyenne*).
- (97.) The preceding results are included in the method of least squares.
- (98.) Risk of a function deduced from the risks of its variables.
- (99.) Caution in the use of the preceding process.
- (100.) Definition of *probable error*. Distinction between it and *mean risk*. The former always about 1.69 of the latter.
- (101.) Analogous distinction in tables of mortality: *mean life* and *probable life*.
- (102.), (103.) Problem of (91.) in the case of *any* law of facility. Justification of (90.)
- (104.) The mean of *two* observations *always* the most probable result: remark on the approximation of (103.).
- (105.) Alteration of form of the result of (103.)
- (106.) Comparison of preceding notation with that of Laplace.
- (107.) Determination of the probability of a given amount in the sum of any functions of errors, all errors being considered as positive.
- (108.) The preceding in the case of the sums of the errors.
- (109.) The same in the case of the sums of the squares of the errors.
- (110.) Approximate determination of the necessary elements.
- (111.) Problem of (107.) in the case where all the functions are different.
- (112.) The same where the negative errors are to be counted as negative.
- (113.) The same where the limits of positive and negative error are different.
- (114.) Consideration of the question of *personal* equation.
- (115.) Consideration of discordant observations, compared with that of their errors. Coincidence of results shown.
- (116.) Rule for the determination of the probable error in an independent form, with example.
- (117.), (118.), (119.), (120.) Description of the tables at the end of the work.
- (121.) Introductory account of the method of least squares.
- (122.) Its coincidence with several common notions.
- (123.) Comparison of the method of least squares with that of averaging.
- (124.) Demonstration in the case of one element to be determined.
- (125.) Coincidence of the result with that of Laplace.
- (126.) Extension to the case where the weights of the observations are not equal.
- (127.) Extension to the case where the unknown element is not determined from an equation of the first degree.
- (128.) Practical method of determining the specific weight of observations.
- (129.) Determination of the mean risk of the result of (124.)
- (130.) Method of least squares, the number of elements to be determined being more than one.
- (131.) The same in the case where the equations are not equally probable.
- (132.) Method of determining the mean risk of the result.
- (133.) Application to the case of two quantities.
- (134.) Artifice for passing from two to three or more elements.
- (135.) Errors in the estimation of the risks of the equation must be considerable before they can materially affect the result of the method of least squares.
- (136.) Remarks on Laplace's *method of situation*.
- (137.) Cases in which the method of least squares fails.
- (138.) The method holds good when positive and negative errors are not equally likely.

(139.—151.) *Miscellaneous applications of the theory of probable fluctuations.*

- (139.) On the question whether observed discrepancies are consequences of a general law, or accidental fluctuations.
- (140.) Method of proceeding in the determination of the most probable cause.
- (141.) Gauss's method of establishing the result in (89.).
- (142.) Application of (69.) to the question of (139.) in the case of one single cause.
- (143.) Application of (68.) to the case of two causes.
- (144.) Application of (60.) to the determination of the presumption that the event which has most often happened is the most probable.
- (145.) Determination of the presumption that increased frequency of an event has a particular cause.
- (146.) Presumption that a table of mortality which represents the past shall represent the future within given limits, on a single set of instances.
- (147.) The same in several instances.
- (148.) Application of the same principle to other problems.
- (149.) Mean risk of fluctuation in the duration of lives
- (150.) Recapitulation of the preceding Articles.
- (151.) Method of estimating the apportionment of *security funds*.
- (152.—162.) *On the mathematical advantage or disadvantage arising from any given prospect.*

- (152.) Statement of principle.
- (153.) Meaning of a negative answer.
- (154.) Determination of the *mean advantage*, and probability of a given amount of fluctuation, in a simple succession of chances.
- (155.), (156.) Principle of the division of risks.
- (157.), (158.) Extension of (154.).
- (159.) Method of constructing tables for the estimation of the probable fluctuations in the gain of an insurance office.
- (160.) Comparison of premiums and single payments.
- (161.) Advantage of *mutual* insurance.
- (162.) Case of (154.), where the probabilities are inferred from given previous observations.

(163.—170.) *On the moral or relative advantage or disadvantage of any given prospect.*

- (163.) Further consideration of (42.).
- (164.) Determination of the moral benefit of a prospect.
- (165.) Case in which this coincides nearly with the mathematical benefit.
- (166.) Risks, mathematically balanced, may be disadvantageous.
- (167.) Coincidence of a result of the method under consideration with a common notion.
- (168.) On the quantity of mathematical advantage which can be given to an insurance office in return for the moral security.
- (169.) The division of risks raises the moral advantage nearly to the mathematical one.
- (170.) Further consideration of the paradox in (40.).

(171.—186.) *Miscellaneous, principally on the probabilities of testimony.*

- (171.), (172.) Application of the theory to a peculiar class of problems.
- (173.), (174.), (175.) Remarks on the application of the calculus of probabilities to moral questions.
- (176.) On the decisions of a jury.
- (177.), (178.), (179.), (180.) On the testimony of a single witness.
- (181.) On the testimony of two or more witnesses.
- (182.) On Hume's argument with respect to miracles.
- (183.) Extension of formulæ by the integral calculus.
- (184.) On tradition.
- (185.) General remarks.
- (186.) Remark on (88.)

DEFINITE INTEGRALS.

Definite Integrals. *Definite Integrals.* Fx being a function of x , whose differential coefficient is fx , and C an arbitrary constant, $Fx+C$ is the **GENERAL INTEGRAL** of fx . If the arbitrary constant C be determined on the hypothesis that this general integral shall vanish when $x=a$, and the *definite* value b be assigned to x , this integral will assume the particular value $Fb-Fa$, and it will have become a **DEFINITE INTEGRAL**: said to be taken between the limits a and b , and written

$\int_a^b fx dx$, the superior limit being placed above and the inferior beneath the sign of integration.

A meaning will be attached to this process of integration, from which its fundamental properties may be deduced, if we revert to that conception of the Integral Calculus in which it originated, and to which many of the terms and symbols of its operations are to be traced, but which has now become a theorem no longer embracing our conception of an integral, but deducible from it.

THEOREM I.—The definite integral $\int_a^b fx dx$ is the limit of the sums of the values severally assumed by the product $fx \cdot \Delta x$, as x is made to vary by successive equal increments of Δx , from a to b , and as each such equal increment is continually and infinitely diminished, and their number therefore continually and infinitely increased.

To prove this, let us suppose that fx does not become infinite for any value of x between a and b , and let any two such values be x and $x+\Delta x$: therefore by Taylor's theorem $F(x+\Delta x) = Fx + \Delta x fx + (\Delta x)^{1+\lambda} M$, where the exponent $1+\lambda$ is given to the third term of the expansion instead of the exponent 2, that the case may be included in which the second differential coefficient of $Fx \frac{d^2fx}{dx^2}$ is infinite, and in which the exponent of Δx in that term is, therefore, a fraction less than 2.

Let the difference between a and b be divided into n equal parts, and let each be represented by Δx , so that

$$\frac{b-a}{n} = \Delta x.$$

Giving to x , then, the successive values $a, a+\Delta x, a+2\Delta x, \dots, a+(n-1)\Delta x$, and adding

$$F(a+n\Delta x) = Fa + \Delta x \sum_1^n f\{a+(n-1)\Delta x\} + (\Delta x)^{1+\lambda} \sum M_n,$$

$$\therefore Fb - Fa = \Delta x \sum_1^n f\{a+(n-1)\Delta x\} + (\Delta x)^{1+\lambda} \sum M_n.$$

Now none of the values of M are infinite, since for none of these values is fx infinite. If, therefore, M be the greatest of these values, then is $\sum M_n$ less than nM , and therefore

$$Fb - Fa - \Delta x \sum_1^n f\{a+(n-1)\Delta x\} < (b-a)M(\Delta x)^\lambda.$$

The difference of the definite integral $Fb - Fa$, and the sum $\sum_1^n \Delta x f\{a+(n-1)\Delta x\}$ is always, therefore, less than $(b-a)M(\Delta x)^\lambda$. Now M is finite, and $(b-a)$ is given, and as n is increased, Δx is diminished continually, and therefore $(\Delta x)^\lambda$ is diminished continually, λ being positive.

Thus by increasing n indefinitely, the difference of the definite integral and the sum may be diminished indefinitely, and therefore in the limit the definite integral is equal to the sum, (*i. e.*)

$$Fb - Fa = \text{limit } \sum_1^n \Delta x \cdot f\{a+(n-1)\Delta x\},$$

or, interpreting this formula, $Fb - Fa$ is the sum of the values of $\Delta x \cdot fx$, when x is made to pass by infinitesimal increments, each represented by Δx , from a to b .*

* This demonstration fails in the case in which fx becomes infinite for any of the supposed values of x ; but M. Poisson has remarked that, analytically, this difficulty will be overcome, provided the transition of x from a to b be made through a series of imaginary values of that variable, in which case none of the corresponding values of fx will be infinite, and the definite integral may receive its ordinary interpretation. Thus, in respect to the integral $\int_{-1}^{+1} \frac{1}{x} dx$, in which $\frac{1}{x}$ becomes infinite for the value 0, through which x passes in its transition from -1 to $+1$, and upon which the ordinary interpretation cannot, therefore, be put in its present form, if we assume $x = -\{\cos z + \sin \sqrt{-1} z\}$; the extreme values ± 1 of x will correspond to the values 0 and $(2n+1)\pi$ of z , and between these the function of $z = \frac{-1}{\cos z + \sin z \sqrt{-1}}$ will not pass through infinity; the definite integral will have, therefore, this substitution being made, its ordinary meaning. Substituting

$$\begin{aligned} \int_{-1}^{+1} \frac{dx}{x} &= \int_0^{(2n+1)\pi} \frac{d\{\cos z + \sin \sqrt{-1} z\}}{\cos z + \sin \sqrt{-1} z} \\ &= \int_0^{(2n+1)\pi} \frac{-\sqrt{-1} dz}{\cos z + \sin \sqrt{-1} z} \\ &= -(2n+1)\pi \sqrt{-1}. \end{aligned}$$

Definite Integrals.

Where the general integral of a function may be determined, the discussion of any definite integral of that function is unnecessary. There are, however, *no* methods of integration which include the whole order of GENERAL INTEGRALS; they extend only to functions of the form of rational fractions, or reducible to that form by a slight transformation. Definite Integrals.

There are, moreover, no *general* methods of DEFINITE INTEGRATION in respect to given limits known. There is, indeed, reason to believe that a large proportion of the functions which are included under the general designation of definite integrals cannot be represented analytically;* and so few, in comparison of what remain, are the definite integrals, including results in physics, which have yet been determined, that our ignorance in this matter may be considered to interpose a barrier on the very threshold of science.

Out of the infinite variety of algebraical formulæ which fx is put to represent, there may, nevertheless, be formed orders or classes of functions, having in a greater or less degree common properties in respect to the process of integration, and reducible in some cases to common methods.

Among these there is an extensive class which it will be convenient to distinguish as periodical functions.

THEOREM II.—A definite integral being considered as the SUM of the products of the infinitesimal quantity beneath the sign of integration by all the successive values of the finite quantity fx , when x is made to pass, by successive equal increments, from one limit to another; it is manifest that, if the finite part be periodical, so that as x is increased by the same quantity a , the same values of fx will return, then will the definite integral, when taken between any two consecutive values of x , differing by a , be the same as when taken between any other two. For each of these definite integrals is a *sum*, and the quantities composing each sum are the same.

Moreover, the integral taken between values of x , differing by n intervals of a , will be n times the value of that integral when taken between limits which differ only by one interval of a . Thus, if fx be a periodical function of x ,

$$\int_0^{na} fx dx = n \int_0^a fx dx \quad \int_b^{b+na} fx dx = n \int_b^{b+a} fx dx.$$

If the value of fx be periodical with respect to the increment a , with this reservation, that for each successive increment it changes its sign, then supposing a series of definite integrals of this function to be taken, whose limits have, in each, an interval of a , it is manifest that these will, by reason of the variation of the sign of fx , have in succession different signs but the same numerical value. Taken then in respect to limits which differ by an even number of intervals of a ,

$$\int_b^{b+na} fx dx = 0,$$

equals nothing; and taken between limits which differ by an odd number of intervals of a ,

$$\int_b^{b+na} fx dx = \pm \int_b^{b+a} fx dx.$$

These properties of periodical integrals appear to point them out as the first to be investigated. And to this class belong the integrals called Elliptic Functions.

The FIRST FIVE sections of the following paper will contain a discussion of the theory of elliptic functions.

In the SIXTH will be discussed the relations of a class of integrals of extensive application, called Eulerian integrals.

The SEVENTH will contain the discussion of formulæ for the expression of the sums of certain series, and the functions of which certain series are the expansions, by definite integrals.

The EIGHTH (conversely), of certain methods by which the value of a function may, between certain limits of the variable on which it depends, be expressed by the sum of a series of periodical definite integrals taken also between those limits. This section will contain the demonstration of the celebrated theorems of Poisson and Fourier.

The NINTH section will be devoted to certain applications of a method of definite integration by differentiation and integration in respect to an arbitrary constant under the sign of integration.

In the TENTH section will be discussed what is known of the theory of ULTRA ELLIPTIC FUNCTIONS.

ELLIPTIC FUNCTIONS.

The definite integrals to which the name of elliptic functions has been given are comprised under the three following forms:

$$\int_0^{\phi_1} \frac{d\phi}{\sqrt{1-k^2 \sin^2 \phi}}, \quad \int_0^{\phi_1} \sqrt{1-k^2 \sin^2 \phi} \cdot d\phi, \quad \int_0^{\phi_1} \frac{d\phi}{(1+n \sin^2 \phi) \sqrt{1-k^2 \sin^2 \phi}};$$

and according as they are included under the FIRST, SECOND, or THIRD of these forms, they are said to be of the FIRST, SECOND, or THIRD ORDERS.

By a similar substitution the definite integral $\int_{-1}^{+1} \frac{dx}{x^m}$ may be determined to be $\frac{(-1)^m}{m-1} \{ \cos(m-1)(2u+1)\pi - 1 \}$, and the ordinary interpretation may be put upon it.

* Laplace states, in the *Mécanique Céleste*, that he has proved the definite integrals, on which depends the theory of the attraction of elliptic spheroids, to be impossible. He has not published this demonstration, and it has not been found among his papers.

Definite
Integrals.

In each order the superior limit ϕ_1 of the integral is called the **AMPLITUDE** of the function, and the arbitrary constant k , supposed always to be less than unity, is called the **MODULUS** of the function.

 Definite
Integrals.

Into functions of the third order there enters a second arbitrary constant n , and this is called the **PARAMETER** of those functions.*

Where the modulus of an elliptic function of either of the three orders is zero or unity, or nearly equal to zero or unity, the value of the integral may be approximated to by the ordinary methods with any required degree of accuracy.

The value of a function having any other modulus is determined either by establishing a relation between it and another having a less modulus, by which its value is made to depend upon that of the other, that upon a third whose modulus is yet less, and so on until its value is eventually made to depend upon that of a function whose modulus is nearly evanescent; or the value of the function is determined by causing this transition from modulus to modulus to be made through an ascending instead of a descending scale, until it is at length made to depend upon the value of a function whose modulus is so near to unity that it may be approximated to by the ordinary methods.

The elliptic function of the **FIRST ORDER** is represented by $Fk\phi_1$; that of the **SECOND ORDER** by $E_k\phi_1$; and that of the **THIRD ORDER** by $\Pi nk\phi_1$.

When the amplitude of a function of either order is a right angle, the function is called a **COMPLETE** function, and written thus,

$$F_k, \quad E_k, \quad \Pi_{nk},$$

The quantity $\sqrt{1 - k^2 \sin^2 \phi}$ is not unfrequently represented by the symbol Δ , or by $\Delta k\phi$.

When an elliptic function F is considered as a function of its amplitude, that amplitude is represented thus amF . The complement of a function is the difference between it and a complete function; and from certain analogies between the properties of these amplitudes of elliptic functions and trigonometrical functions, the amplitude of the complement of a function F has come to be called the **coamplitude** of that function, and written $coam F$.

The first step taken in the theory of elliptic functions was the determination of a relation between the amplitudes of three functions of either order, such that there should exist an algebraical relation between the three functions themselves, of which these were the amplitudes. It is one of the most remarkable of the discoveries which science owes to the illustrious **EULER**. In the year 1761 he gave to the world the complete integration of an equation of two terms, each an elliptic function of the first or second order, not *separately* integrable;† of which integration the arbitrary constant, introduced a third function, related to the first two by a given equation between the amplitudes of the three.

This integration involved, in respect to functions of the second order, a property of the ellipse or the hyperbola, before discovered by **FAGANI**,‡ by which property two arcs differing from one another by an assignable algebraical quantity may be taken on either of these curves in an infinite number of different ways; and the properties of the lemniscata in reference to a function of the first order having the modulus $\frac{1}{\sqrt{2}}$, discovered by the same Italian philosopher.

In 1775 **LANDEN**, an English mathematician, published his celebrated theorem, showing that any arc of an hyperbola may be measured by two arcs of an ellipse. An important element of the theory of elliptic functions as it has since been developed, but *then* an isolated result.

The great problem of the comparison of elliptic functions having different moduli remained unsolved; and it is a remarkable fact that, although Euler had in a measure exhausted the comparison of functions of the same modulus, this of functions having different moduli he left untouched. It was completed in 1784 by **LAGRANGE**,§ and in respect to the determination of the numerical values of elliptic functions the comparison of Lagrange may be considered to leave little to be wished for. The value of a function may be determined by it in terms of a series of functions whose moduli continually increase or diminish, until at length this relation becomes one between the proposed function and a function having a modulus indefinitely near to unity or zero.

For all practical purposes this was sufficient; and all that remained in respect to functions of the first and second orders was to calculate for a series of values of k , extending by sufficiently small intervals from 0 to k , the numerical value of each function corresponding to a given amplitude, and to do this for each amplitude between 0 and 90°.

This herculean task was undertaken by **LEGENDRE**. At enormous labour, and with his own hand, he completed tables of elliptic functions, in which are to be found their numerical values for each degree of amplitude between 0 and 90°, and for every value of the modulus k determined by a degree of the angle $\sin^{-1} k$ between the same limits.

The labours of Legendre in the advancement of this branch of analytical knowledge were not, however, confined

* Any function of the second order may be represented by the arc of an ellipse; and it is from this circumstance that the name of elliptic functions has been made to distinguish the whole class of which this order of functions forms a part.

All integrals embraced under the form $\int_0^x \frac{fx dx}{\sqrt{a+bx+cx^2+fx^4}}$, where fx is any rational function of x , may be made to depend for their integration upon the integration of elliptic functions. See Legendre, *Fonctions Elliptiques*, vol i. ch. i.; or Hymer's *Integ. Cal.*, p. 184.

Definite
Integrals.

to the calculation of these tables. There is none of the discoveries of his predecessors in it which has not received more or less of perfection at his hands; and it was he who first supplied to the whole that connection and arrangement which have constituted it an independent science. Although to the numerical calculation of the values of elliptic integrals the method of Lagrange was sufficient, yet to the theory of elliptic functions it was insufficient. His relation between two functions having different moduli had about it all the characteristics of a particular case of some more general theorem, of which general theorem a second particular case was afterwards discovered by Legendre.

Definite
Integrals.

Here, nevertheless, the science remained. From the year 1786, when Legendre took it up, until the year 1827, when the second volume of his work (*Traité des Fonctions Elliptiques*) was published, the labours of no other philosopher of eminence were superadded. It had been in a great measure the business of his life, and he had pursued it alone. Scarcely, however, had his work passed from the hands of the printer, when it became known to the scientific world that the theory of elliptic functions was placed upon a new basis, and had received a new and extraordinary developement by the independent labours of two mathematicians, whose names were comparatively new in science. The researches of JACOBI, professor of mathematics in Königsburg, in the theory of elliptic functions were first published in the 123d Number of the *Journal of Schumacher*, and those of ABEL, professor of mathematics at Christiana, in the 3d Number of the *Journal of Crelle* for the year 1827. Three supplements to the great work of Legendre contain an account of these discoveries, the publication of the last of which but a little preceded his death.

The researches of Jacobi have for their principal object the developement of that general relation of functions of the first order having different moduli, of which the scales of Lagrange and Legendre are particular cases. This branch of the subject he has pursued with extraordinary sagacity, and he may be said almost to have perfected it.

It was to Abel that the idea first occurred of treating the elliptic integral as a function of its amplitude; and, proceeding from this new point of view, he embraced in his speculations all the principal results of Jacobi. In some of the most important of these, as in the developement of the properties of functions directly and inversely by the introduction of imaginary quantities, he undoubtedly preceded him; but in that particular theorem which is called the theorem of Jacobi, by which so much light is thrown on the investigations of preceding mathematicians, although the discovery of it appears to have been made by both nearly at the same time, yet the priority of publication is undoubtedly with Jacobi. It is not, however, by discoveries, in which he divides the honour with Jacobi, that Abel has rendered his name immortal, but by his contributions to this branch of analysis.

Having undertaken to develop the principle on which rests the fundamental proposition of Euler, establishing an algebraical relation between three functions which have the same modulus, dependent upon a certain relation of their amplitudes, he has extended it from three to an indefinite number of functions, and from elliptic functions to an infinity of other functions embraced under an indefinite number of classes, of which that of elliptic functions is but one, and of which each class has a division analogous to that of elliptic functions into three orders having common properties.

The discovery of Abel is of infinite moment, as presenting the first step of approach towards a more complete theory of the infinite class of ultra-elliptic functions, destined probably ere long to constitute one of the most important of the branches of transcendental analysis, and to include among the integrals of which it effects the solution some of those which at present arrest the researches of the philosopher in the very elements of physics.

Abel died in 1828, at Christiansand, in Norway, at the age of twenty-seven. Science has had in our times no greater loss to deplore.

In the FIRST SECTION of the following paper it will be shown, that if there be three elliptic functions having the same modulus k between the amplitudes ϕ_1, ϕ_2, ϕ_3 , of which there obtains the relation

$$\cos \phi_3 = \cos \phi_1 \cos \phi_2 - \sin \phi_1 \sin \phi_2 \Delta \phi_1 \dots \dots \dots (1.);$$

then among the functions themselves, of which these are the amplitudes, will there exist, according to the orders to which they severally belong, the following transcendental equations:

$$F\phi_1 + F\phi_2 - F\phi_3 = 0 \dots \dots \dots (2.)$$

$$E\phi_1 + E\phi_2 - E\phi_3 = k^2 \sin \phi_1 \sin \phi_2 \sin \phi_3 \dots \dots \dots (3.)$$

$$\Pi\phi_1 + \Pi\phi_2 - \Pi\phi_3 = \sqrt{\frac{n}{(n+1)(n+k^2)}} \tan^{-1} \left\{ \frac{\{n(n+1)(n+k^2)\}^{\frac{1}{2}} \sin \phi_1 \sin \phi_2 \sin \phi_3}{1+n(1-\cos \phi_1 \cos \phi_2 \cos \phi_3)} \right\} \dots \dots \dots (4.)$$

Moreover that this relation will obtain in respect to the equations (1.) and (2.), if the sign of ϕ_2 be changed.

It will be shown in the SECOND SECTION that these are but particular cases of a more extensive theorem, embracing, with the necessary modifications, every order of ultra elliptic functions, and extending to any number of functions in each order.

In the THIRD SECTION, the general relations of two functions which have different moduli will be investigated.

In the FOURTH, these relations will be applied to the determination of the numerical values of elliptic functions.

The FIFTH will contain the discussion of certain relations of elliptic functions to the parts of a spherical triangle, and to the lengths of the arcs of certain curves.

The equation of condition (1.) admits of the following transformations, all of which have their application in the theory of elliptic functions, and which are therefore given here once for all.

$$^{(1.)} \cos^2 \phi_1 + \cos^2 \phi_2 + \cos^2 \phi_3 - 2 \cos \phi_1 \cos \phi_2 \cos \phi_3 = 1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2 \sin^2 \phi_3 \dots \dots \dots (5.)*$$

* ^(1.) This equation is obtained simply by clearing equation (1.) of the radicals which enter into it, and transposing it.

^(2.) Adding $\cos^2 \phi_1 \cos^2 \phi_2$ to both sides of equation (5.), and transposing, we have

Definite
Integrals.

 Definite
Integrals.

$$^{(2)} \cos \phi_1 = \cos \phi_2 \cos \phi_3 + \sin \phi_2 \sin \phi_3 \Delta \phi_1 \dots \dots \dots (6.)$$

$$^{(3)} \cos \phi_2 = \cos \phi_1 \cos \phi_3 + \sin \phi_1 \sin \phi_3 \Delta \phi_2 \dots \dots \dots (7.)$$

$$^{(4)} \sin \phi_3 = \frac{\sin \phi_1 \cos \phi_2 \Delta \phi_2 + \sin \phi_2 \cos \phi_1 \Delta \phi_1}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2} \dots \dots \dots (8.)$$

$$^{(5)} \cos \phi_3 = \frac{\cos \phi_1 \cos \phi_2 - \sin \phi_1 \sin \phi_2 \Delta \phi_1 \Delta \phi_2}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2} \dots \dots \dots (9.)$$

$$^{(6)} \Delta \phi_1 \Delta \phi_2 - \Delta \phi_3 = k^2 \sin \phi_1 \sin \phi_2 \cos \phi_3 \dots \dots \dots (10.)$$

$$^{(7)} \Delta \phi_1 \Delta \phi_2 \Delta \phi_3 = k'^2 + k^2 \cos \phi_1 \cos \phi_2 \cos \phi_3 \dots \dots \dots (11.)$$

SECTION I.

THEOREM III.—If there exist between the amplitudes ϕ_1, ϕ_2, ϕ_3 of three functions of the first order the relation

$$\cos \phi_3 = \cos \phi_1 \cos \phi_2 - \sin \phi_1 \sin \phi_2 \Delta \phi_3,$$

then will there exist between the functions themselves the relations

$$F\phi_1 + F\phi_2 - F\phi_3 = 0.$$

Dividing the equation of condition by $\sin \phi_1 \sin \phi_2$, and differentiating with respect to ϕ_1 and ϕ_2 , these being considered functions of a third variable ϕ ,

$$\frac{d\phi_1}{d\phi} \left\{ \frac{\cos \phi_2 - \cos \phi_1 \cos \phi_3}{\sin \phi_1} \right\} + \frac{d\phi_2}{d\phi} \left\{ \frac{\cos \phi_1 - \cos \phi_2 \cos \phi_3}{\sin \phi_2} \right\} = 0.$$

Substituting in this equation the values of

$$\frac{\cos \phi_1 - \cos \phi_2 \cos \phi_3}{\sin \phi_2} \quad \text{and} \quad \frac{\cos \phi_2 - \cos \phi_1 \cos \phi_3}{\sin \phi_1}$$

from equations (6.) and (7.) we have

$$\frac{\left(\frac{d\phi_1}{d\phi} \right)}{\Delta \phi_1} + \frac{\left(\frac{d\phi_2}{d\phi} \right)}{\Delta \phi_2} = 0;$$

$\therefore$ integrating $F\phi_1 + F\phi_2 - F\phi_3 = 0$, ϕ_3 being the value of ϕ_1 when $\phi_2 = 0$.

THEOREM IV.—If there exist between the amplitudes of three functions of the FIRST ORDER the relation

$$\cos \phi_3 = \cos \phi_1 \cos \phi_2 + \sin \phi_1 \sin \phi_2 \Delta \phi_3,$$

then will there exist between the functions themselves the relation

$$\begin{aligned} \{ \cos \phi_1 - \cos \phi_2 \cos \phi_3 \}^2 &= 1 - \cos^2 \phi_2 - \cos^2 \phi_3 + \cos^2 \phi_2 \cos^2 \phi_3 - k^2 \sin^2 \phi_1 \sin^2 \phi_2 \sin^2 \phi_3 \\ &= \sin^2 \phi_2 \sin^2 \phi_3 - k^2 \sin^2 \phi_1 \sin^2 \phi_2 \sin^2 \phi_3 \\ &= \sin^2 \phi_2 \sin^2 \phi_3 \Delta^2 \phi_1 \\ \cos \phi_1 &= \cos \phi_2 \cos \phi_3 + \sin \phi_2 \sin \phi_3 \Delta \phi_1, \end{aligned}$$

using the sign + because it appears by equation (2.) that when $\phi_1 = 0$ $\phi_2 = \phi_3$.

^(3.) This equation is obtained by a similar transposition to the last, *mutatis mutandis*.

^(4.) Multiplying (6.) by $\cos \phi_1$, and (7.) by $\cos \phi_2$, and adding, we have

$$\cos^2 \phi_1 + \cos^2 \phi_2 - 2 \cos \phi_1 \cos \phi_2 \cos \phi_3 - \sin \phi_3 \{ \cos \phi_1 \sin \phi_2 \Delta \phi_2 + \cos \phi_2 \sin \phi_1 \Delta \phi_1 \} = 0.$$

Subtracting this equation from (5.),

$$\sin^2 \phi_3 = \sin \phi_3 \{ \cos \phi_1 \sin \phi_2 \Delta \phi_2 + \cos \phi_2 \sin \phi_1 \Delta \phi_1 \} + k^2 \sin^2 \phi_1 \sin^2 \phi_2 \sin^2 \phi_3;$$

$$\therefore \sin \phi_3 = \frac{\cos \phi_1 \sin \phi_2 \Delta \phi_2 + \cos \phi_2 \sin \phi_1 \Delta \phi_1}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2}$$

^(5.) Substituting this value of $\sin \phi_3$ in (6.),

$$\cos \phi_1 = \cos \phi_2 \cos \phi_3 + \frac{\sin \phi_1 \sin \phi_2 \cos \phi_2 \Delta \phi_1 \Delta \phi_2 + \sin^2 \phi_2 \cos \phi_1 (\Delta \phi_1)^2}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2};$$

$$\therefore \cos \phi_2 \cos \phi_3 = \frac{\cos \phi_1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2 \cos \phi_1 - \sin \phi_1 \sin \phi_2 \cos \phi_2 \Delta \phi_1 \Delta \phi_2 - \sin^2 \phi_2 \cos \phi_1 (\Delta \phi_1)^2}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2}$$

$$= \frac{\cos \phi_1 - \sin^2 \phi_2 \cos \phi_1 - \sin \phi_1 \sin \phi_2 \cos \phi_2 \Delta \phi_1 \Delta \phi_2}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2}$$

$$\therefore \cos \phi_3 = \frac{\cos \phi_1 \cos \phi_2 - \sin \phi_1 \sin \phi_2 \Delta \phi_1 \Delta \phi_2}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2}$$

^(6.) Transposing (7.),

$$\cos \phi_3 - \cos \phi_1 \cos \phi_2 = k^2 \sin^2 \phi_1 \sin^2 \phi_2 \cos \phi_3 - \sin \phi_1 \sin \phi_2 \Delta \phi_1 \Delta \phi_2;$$

$\therefore$ by equation (4.),

$$-\sin \phi_1 \sin \phi_2 \Delta \phi_3 = k^2 \sin^2 \phi_1 \sin^2 \phi_2 \cos \phi_3 - \sin \phi_1 \sin \phi_2 \Delta \phi_1 \Delta \phi_2;$$

$$\therefore \Delta \phi_1 \Delta \phi_2 - \Delta \phi_3 = k^2 \sin \phi_1 \sin \phi_2 \cos \phi_3.$$

^(7.) Multiplying equation (10.) by $\Delta \phi_3$,

$$\Delta \phi_1 \Delta \phi_2 \Delta \phi_3 - \Delta^2 \phi_3 = k^2 \sin \phi_1 \sin \phi_2 \cos \phi_3 \Delta \phi_3;$$

also by (1.)

$$-k^2 \cos^2 \phi_3 = -k^2 \cos \phi_1 \cos \phi_2 \cos \phi_3 + k^2 \sin \phi_1 \sin \phi_2 \cos \phi_3 \Delta \phi_3;$$

$\therefore$ by subtraction

$$\Delta \phi_1 \Delta \phi_2 \Delta \phi_3 - 1 + k^2 = k^2 \cos \phi_1 \cos \phi_2 \cos \phi_3;$$

or

$$\Delta \phi_1 \Delta \phi_2 \Delta \phi_3 = k'^2 + k^2 \cos \phi_1 \cos \phi_2 \cos \phi_3, \text{ assuming } k'^2 = 1 - k^2.$$

Definite
Integrals.

$$F\phi_1 - F\phi_2 - F\phi_3 = 0.$$

The proof of this theorem is, *mutatis mutandis*, precisely the same as that of the last.*

Definite
Integrals.

* Hence therefore, generally, in respect to functions of the first order, it is shown that, if

$$\cos \phi_3 = \cos \phi_1 \cos \phi_2 \mp \sin \phi_1 \sin \phi_2 \Delta \phi_3,$$

then $F\phi_1 \pm F\phi_2 - F\phi_3 = 0$. The converse of this proposition may be proved. It may be shown that, if these obtain the relation $F\phi_1 \pm F\phi_2 - F\phi_3 = 0$ between three functions, then will there obtain the relation $\cos \phi_3 = \cos \phi_1 \cos \phi_2 \mp \sin \phi_1 \sin \phi_2 \Delta \phi_3$ between the amplitudes of those functions. The following is the integration of Euler.

Differentiating with respect to ϕ_1, ϕ_2 assumed to be functions of a third variable ϕ , we have

$$\frac{\frac{d\phi_1}{d\phi}}{\sqrt{1-k^2 \sin^2 \phi_1}} \pm \frac{\frac{d\phi_2}{d\phi}}{\sqrt{1-k^2 \sin^2 \phi_2}} = 0.$$

Now ϕ may be any whatever, ϕ_1 may then be any function whatever of ϕ . Let ϕ_1 be that function of ϕ which satisfies the equation

$$\left. \begin{aligned} \frac{\frac{d\phi_1}{d\phi}}{\sqrt{1-k^2 \sin^2 \phi_1}} &= 1 \\ \frac{\frac{d\phi_2}{d\phi}}{\sqrt{1-k^2 \sin^2 \phi_2}} &= \mp 1 \end{aligned} \right\} \dots\dots (\alpha),$$

$$\therefore \frac{d\phi_1}{d\phi} = \sqrt{1-k^2 \sin^2 \phi_1}, \quad \frac{d\phi_2}{d\phi} = \mp \sqrt{1-k^2 \sin^2 \phi_2}.$$

Squaring these equations, and differentiating them, we have

$$2 \frac{d\phi_1}{d\phi} \frac{d^2 \phi_1}{d\phi^2} = -2k^2 \sin \phi_1 \cos \phi_1 \frac{d\phi_1}{d\phi}$$

$$2 \frac{d\phi_2}{d\phi} \frac{d^2 \phi_2}{d\phi^2} = -2k^2 \sin \phi_2 \cos \phi_2 \frac{d\phi_2}{d\phi},$$

or

$$\frac{d^2 \phi_1}{d\phi^2} = -\frac{1}{2} k^2 \sin 2\phi_1, \quad \frac{d^2 \phi_2}{d\phi^2} = -\frac{1}{2} k^2 \sin 2\phi_2;$$

$$\therefore \frac{d^2 (\phi_1 \pm \phi_2)}{d\phi^2} = -\frac{1}{2} k^2 (\sin 2\phi_1 \pm \sin 2\phi_2);$$

$$\therefore \frac{d^2 (\phi_1 + \phi_2)}{d\phi^2} = -k^2 \sin (\phi_1 + \phi_2) \cos (\phi_1 - \phi_2),$$

$$\frac{d^2 (\phi_1 - \phi_2)}{d\phi^2} = -k^2 \sin (\phi_1 - \phi_2) \cos (\phi_1 + \phi_2).$$

Also

$$\frac{d(\phi_1 + \phi_2)}{d\phi} \cdot \frac{d(\phi_1 + \phi_2)}{d\phi} = \left(\frac{d\phi_1}{d\phi} \right)^2 - \left(\frac{d\phi_2}{d\phi} \right)^2$$

$$= -k^2 (\sin^2 \phi_1 - \sin^2 \phi_2)$$

$$= -k^2 \sin (\phi_1 + \phi_2) \sin (\phi_1 - \phi_2);$$

$$\therefore \left\{ \frac{d^2 (\phi_1 + \phi_2)}{d\phi^2} \right\} = \left\{ \frac{d(\phi_1 - \phi_2)}{d\phi} \right\} \cdot \frac{\cos (\phi_1 - \phi_2)}{\sin (\phi_1 - \phi_2)}$$

$$\left\{ \frac{d^2 (\phi_1 - \phi_2)}{d\phi^2} \right\} = \frac{d(\phi_1 + \phi_2)}{d\phi} \cdot \frac{\cos (\phi_1 + \phi_2)}{\sin (\phi_1 + \phi_2)}.$$

$$\left. \begin{aligned} \frac{d(\phi_1 + \phi_2)}{d\phi} &= C_1 \sin (\phi_1 - \phi_2) \\ \frac{d(\phi_1 - \phi_2)}{d\phi} &= C_2 \sin (\phi_1 + \phi_2) \end{aligned} \right\} \dots\dots (\beta).$$

$\therefore$ integrating

Reversing the lower of these equations, and multiplying, we have

$$C_2 \sin (\phi_1 + \phi_2) \frac{d(\phi_1 + \phi_2)}{d\phi} = C_1 \sin (\phi_1 - \phi_2) \frac{d(\phi_1 - \phi_2)}{d\phi};$$

$$\therefore C_2 \cos (\phi_1 + \phi_2) = C_1 \cos (\phi_1 - \phi_2) + C_3;$$

$$\therefore (C_2 - C_1) \cos \phi_1 \cos \phi_2 - (C_2 + C_1) \sin \phi_1 \sin \phi_2 = C_3 \dots\dots (\gamma).$$

It remains to determine the constants. Adding and subtracting equation (β), and observing that by equation (α)

$$\frac{d\phi_1}{d\phi} = \Delta \phi_1, \quad \frac{d\phi_2}{d\phi} = \mp \Delta \phi_2,$$

we have

$$(C_2 + C_1) \sin \phi_1 \cos \phi_2 + (C_2 - C_1) \sin \phi_2 \cos \phi_1 = 2 \Delta \phi_1$$

$$-(C_2 + C_1) \sin \phi_2 \cos \phi_1 - (C_2 - C_1) \sin \phi_1 \cos \phi_2 = \mp 2 \Delta \phi_2.$$

Definite
Integrals.

THEOREM V.—If there exist between the amplitudes of three functions of the SECOND ORDER the relation

$$\cos \phi_3 = \cos \phi_1 \cos \phi_2 - \sin \phi_1 \sin \phi_2 \Delta \phi_3,$$

then will there exist between the function the relation

$$E\phi_1 + E\phi_2 - E\phi_3 = k^2 \sin \phi_1 \sin \phi_2 \sin \phi_3.$$

Let

$$E\phi_1 + E\phi_2 - E\phi_3 = \Phi;$$

$$\therefore \frac{d\phi_1}{d\phi} \Delta \phi_1 + \frac{d\phi_2}{d\phi} \Delta \phi_2 = \frac{d\Phi}{d\phi};$$

 $\therefore$ substituting the values of $\Delta \phi_1$ and $\Delta \phi_2$ from equations (6.) and (7.),

$$\frac{d\phi_1}{d\phi} \left\{ \frac{\cos \phi_1 - \cos \phi_2 \cos \phi_3}{\sin \phi_2 \sin \phi_3} \right\} + \frac{d\phi_2}{d\phi} \left\{ \frac{\cos \phi_2 - \cos \phi_1 \cos \phi_3}{\sin \phi_1 \sin \phi_3} \right\} = \frac{d\Phi}{d\phi};$$

$$\therefore \frac{\frac{d\phi_1}{d\phi} \{ \sin \phi_1 \cos \phi_1 - \cos \phi_2 \cos \phi_3 \sin \phi_1 \} + \frac{d\phi_2}{d\phi} \{ \sin \phi_2 \cos \phi_2 - \cos \phi_1 \cos \phi_3 \sin \phi_2 \}}{\sin \phi_1 \sin \phi_2 \sin \phi_3} = \frac{d\Phi}{d\phi};$$

$$\therefore \frac{\frac{d}{d\phi} \left\{ \frac{1}{2} \sin^2 \phi_1 + \frac{1}{2} \sin^2 \phi_2 + \cos \phi_1 \cos \phi_2 \cos \phi_3 \right\}}{\sin \phi_1 \sin \phi_2 \sin \phi_3} = \frac{d\Phi}{d\phi}.$$

But, by equation (5.),

$$\sin^2 \phi_1 + \sin^2 \phi_2 + 2 \cos \phi_1 \cos \phi_2 \cos \phi_3 = 1 + \cos^2 \phi_3 + k^2 \sin^2 \phi_1 \sin^2 \phi_2 \sin^2 \phi_3;$$

$$\therefore \frac{1}{2} k^2 \frac{d}{d\phi} \{ \sin^2 \phi_1 \sin^2 \phi_2 \sin^2 \phi_3 \} = \frac{d\Phi}{d\phi}.$$

$$\therefore k^2 \frac{d \{ \sin \phi_1 \sin \phi_2 \sin \phi_3 \}}{d\phi} = \frac{d\Phi}{d\phi};$$

$$\therefore k^2 \sin \phi_1 \sin \phi_2 \sin \phi_3 = \Phi,$$

no constant being added, because Φ , that is, $E\phi_1 + E\phi_2 - E\phi_3$ vanishes when $\phi_2 = 0$; and $\therefore$, by the equation of condition, $\phi_1 = \phi_3$. Therefore, if

$$\cos \phi_3 = \cos \phi_1 \cos \phi_2 - \sin \phi_1 \sin \phi_2 \Delta \phi_3,$$

then

$$E\phi_1 + E\phi_2 - E\phi_3 = k^2 \sin \phi_1 \sin \phi_2 \sin \phi_3.*$$

THEOREM V.—If there exist between the amplitudes of three functions of the THIRD ORDER the relation

$$\cos \phi_3 = \cos \phi_1 \cos \phi_2 - \sin \phi_1 \sin \phi_2 \Delta \phi_3,$$

then will there exist between the functions the relation

$$\Pi \phi_1 + \Pi \phi_2 - \Pi \phi_3 = \frac{n}{N} \tan^{-1} \left\{ \frac{N \sin \phi_1 \sin \phi_2 \sin \phi_3}{1 + n (1 - \cos \phi_1 \cos \phi_2 \cos \phi_3)} \right\},$$

where $N = \sqrt{n(n+1)(n+k^2)}$.

Let

$$\Pi \phi_1 + \Pi \phi_2 - \Pi \phi_3 = \Phi;$$

 $\therefore$ differentiating with respect to ϕ_1 and ϕ_2 ,

$$\frac{\left(\frac{d\phi_1}{d\phi} \right)}{(1 + n \sin^2 \phi_1) \Delta \phi_1} + \frac{\left(\frac{d\phi_2}{d\phi} \right)}{(1 + n \sin^2 \phi_2) \Delta \phi_2} = \frac{d\Phi}{d\phi} \dots \dots \dots (A.)$$

Now if

$$\phi_2 = 0, F\phi_1 - F\phi_3 = 0; \therefore \phi_1 = \phi_3;$$

$$\therefore (C_2 + C_1) \sin \phi_3 = 2 \Delta \phi_3$$

$$(C_2 - C_1) \sin \phi_3 = \pm 2 \Delta 0 = \pm 2.$$

Substituting these values in equation (7),

$$\pm 2 \cos \phi_1 \cos \phi_2 - 2 \sin \phi_1 \sin \phi_2 \Delta \phi_3 = C_3 \sin \phi_3;$$

and again, making $\phi_2 = 0$,

$$\pm 2 \cos \phi_3 = C \sin \phi_3;$$

$$\therefore \cos \phi_3 = \cos \phi_1 \cos \phi_2 \mp \sin \phi_1 \sin \phi_2 \Delta \phi_3.$$

* The converse of this proposition is not true. Differentiating equation (3.) with respect to ϕ ,

$$\frac{d\phi_1}{d\phi} \Delta \phi_1 + \frac{d\phi_2}{d\phi} \Delta \phi_2 = k^2 \left\{ \sin \phi_2 \cos \phi_1 \frac{d\phi_1}{d\phi} + \sin \phi_1 \cos \phi_2 \frac{d\phi_2}{d\phi} \right\} \sin \phi_3;$$

 $\therefore$, see the preceding note,

$$(\Delta \phi_1)^2 - (\Delta \phi_2)^2 = \{ \sin \phi_2 \cos \phi_1 \Delta \phi_1 - \sin \phi_1 \cos \phi_2 \Delta \phi_2 \} \sin \phi_3;$$

$$\therefore \cos^2 \phi_1 - \cos^2 \phi_2 = \sin \phi_2 \sin \phi_3 \cos \phi_1 \Delta \phi_1 - \sin \phi_1 \sin \phi_3 \cos \phi_2 \Delta \phi_2,$$

subtracting $\cos \phi_1, \cos \phi_2, \cos \phi_3$, from both sides, and transposing

$$\cos \phi_1 \{ \cos \phi_1 - (\cos \phi_2 \cos \phi_3 + \sin \phi_2 \sin \phi_3 \Delta \phi_1) \} - \cos \phi_2 \{ \cos \phi_2 - (\cos \phi_1 \cos \phi_3 + \sin \phi_1 \sin \phi_3 \Delta \phi_2) \} = 0.$$

Now this equation is satisfied, if equation (1.) obtain, because then equations (6.) and (7.) will obtain. But the converse of this is not necessarily true. The relation expressed in this equation does not necessarily imply that of equation (1.). Equation (1.), between the amplitudes, is therefore sufficient to equation (3.) between the functions, but it is not necessary to it.

Definite
Integrals.

Definite
Integrals.

Now by equations (2.) and (3.), to which the equation of condition has been shown to be sufficient,

Definite
Integrals.

$$\frac{\left(\frac{d\phi_1}{d\phi}\right)}{\Delta\phi_1} + \frac{\left(\frac{d\phi_2}{d\phi}\right)}{\Delta\phi_2} = 0 \dots\dots\dots (B.),$$

$$\left(\frac{d\phi_1}{d\phi}\right)\Delta\phi_1 + \left(\frac{d\phi_2}{d\phi}\right)\Delta\phi_2 = k^2 \frac{d\{\sin\phi_1 \sin\phi_2 \sin\phi_3\}}{d\phi} \dots\dots\dots (C.);$$

 $\therefore$ by (A.) and (B.)

$$\frac{\left(\frac{d\phi_1}{d\phi}\right)}{\Delta\phi_1} \left\{ \frac{1}{(1+n\sin^2\phi_1)} - \frac{1}{(1+n\sin^2\phi_2)} \right\} = \frac{d\Phi}{d\phi}$$

or

$$\frac{\left(\frac{d\phi_1}{d\phi}\right)}{\Delta\phi_1} \left\{ \frac{n(\sin^2\phi_2 - \sin^2\phi_1)}{(1+n\sin^2\phi_1)(1+n\sin^2\phi_2)} \right\} = \frac{d\Phi}{d\phi};$$

but by (B.) and (C.)

$$\{(\Delta\phi_1)^2 - (\Delta\phi_2)^2\} \frac{d\phi_1}{d\phi} = k^2 \frac{d\{\sin\phi_1 \sin\phi_2 \sin\phi_3\}}{d\phi},$$

$$\therefore \{\sin^2\phi_2 - \sin^2\phi_1\} \frac{d\phi_1}{d\phi} = \frac{d\{\sin\phi_1 \sin\phi_2 \sin\phi_3\}}{d\phi};$$

$$\therefore n \frac{\frac{d}{d\phi} \{\sin\phi_1 \sin\phi_2 \sin\phi_3\}}{(1+n\sin^2\phi_1)(1+n\sin^2\phi_2)} = \frac{d\Phi}{d\phi}.$$

Let

$$\sin\phi_1 \sin\phi_2 = \frac{1}{P};$$

by equation (1.)

$$\therefore \cos\phi_1 \cos\phi_2 = \cos\phi_3 + \frac{\Delta\phi_3}{P};$$

$$\therefore (1 - \sin^2\phi_1)(1 - \sin^2\phi_2) = \left\{ \cos\phi_3 + \frac{\Delta\phi_3}{P} \right\}^2;$$

$$\therefore \sin^2\phi_1 + \sin^2\phi_2 = \sin^2\phi_3 - 2 \frac{\cos\phi_3 \Delta\phi_3}{P} + \frac{k^2 \sin^2\phi_3}{P^2};$$

$$\therefore (1 + n\sin^2\phi_1)(1 + n\sin^2\phi_2) = 1 + n\sin^2\phi_3 - 2n \frac{\cos\phi_3 \Delta\phi_3}{P} + \frac{n^2 + nk^2 \sin^2\phi_3}{P^2};$$

$$\therefore \frac{n \sin\phi_3 \left(\frac{dP^{-1}}{d\phi}\right)}{1 + n\sin^2\phi_3 - 2n \frac{\cos\phi_3 \Delta\phi_3}{P} + \frac{n^2 + nk^2 \sin^2\phi_3}{P^2}} = \frac{d\Phi}{d\phi};$$

$$\therefore \frac{-n \sin\phi_3 \left(\frac{dP}{d\phi}\right)}{P^2(1 + n\sin^2\phi_3) - 2Pn \cos\phi_3 \Delta\phi_3 + (n^2 + nk^2 \sin^2\phi_3)} = \frac{d\Phi}{d\phi}.$$

Integrating by the ordinary rules,

$$\Phi = \left\{ \frac{n}{(n+1)(n+k^2)} \right\}^{\frac{1}{2}} \cot^{-1} \left\{ \frac{P(1 + n\sin^2\phi_3) - n \cos\phi_3 \Delta\phi_3}{\{n(n+1)(n+k^2)\}^{\frac{1}{2}} \sin\phi_3} \right\},$$

or

$$\Phi = \frac{n}{N} \cot^{-1} \left\{ \frac{1 + n\sin^2\phi_3 - n \sin\phi_1 \sin\phi_2 \cos\phi_3 \Delta\phi_3}{N \sin\phi_1 \sin\phi_2 \sin\phi_3} \right\}.$$

Now

$$1 + n\sin^2\phi_3 - n \sin\phi_1 \sin\phi_2 \cos\phi_3 \Delta\phi_3 = 1 + n - n \cos\phi_3 \{\cos\phi_3 - \sin\phi_1 \sin\phi_2 \Delta\phi_3\}$$

$$\dots\dots\dots = 1 + n - n \cos\phi_1 \cos\phi_2 \cos\phi_3;$$

$$\therefore \Phi = \frac{n}{N} \tan^{-1} \left\{ \frac{N \sin\phi_1 \sin\phi_2 \sin\phi_3}{1 + n(1 - \cos\phi_1 \cos\phi_2 \cos\phi_3)} \right\};$$

 $\therefore$ &c.** In the case in which n is negative, the integral assumes a logarithmic form.

Let

$$n = -k^2 \sin^2\theta;$$

$$\therefore \frac{N}{n} = \cot\theta \Delta\theta \sqrt{-1};$$

$$\therefore \Phi = \frac{\tan\theta}{\Delta\theta} \cdot \frac{1}{\sqrt{-1}} \tan^{-1} \left\{ \sqrt{-1} \cdot \frac{\cot\theta \Delta\theta \sin\phi_1 \sin\phi_2 \sin\phi_3}{1 + n(1 - \cos\phi_1 \cos\phi_2 \cos\phi_3)} \right\};$$

$$\therefore \Phi = \frac{1}{2} \frac{\tan\theta}{\Delta\theta} \log \left\{ \frac{1 + \left\{ \frac{\cot\theta \Delta\theta \sin\phi_1 \sin\phi_2 \sin\phi_3}{1 + n(1 - \cos\phi_1 \cos\phi_2 \cos\phi_3)} \right\}}{1 - \left\{ \frac{\cot\theta \Delta\theta \sin\phi_1 \sin\phi_2 \sin\phi_3}{1 + n(1 - \cos\phi_1 \cos\phi_2 \cos\phi_3)} \right\}} \right\}.$$

Definite
Integrals.

SECTION II.—THE THEOREM OF ABEL.

 Definite
Integrals.

The preceding theorems are particular cases of a general theorem, extending to any number of functions, and to any order of functions included under the formula $\int \frac{fx \cdot dx}{(x-\alpha) \sqrt{\phi x}}$, where fx and ϕx are any function of x .

THEOREM VI.—Let $\psi x_1, \psi x_2, \dots$ represent the definite values of the integral $\int \frac{fx \cdot dx}{(x-\alpha) \sqrt{\phi x}}$ when taken between values of x , 0, and $x_1, x_2, x_3, \dots$ respectively.

Also let ϕx be the product of any two factors $\phi_1 x$ and $\phi_2 x$, respectively of n_1 and n_2 dimensions in x . Let $\theta_1 x$ and $\theta_2 x$ be polynomials ascending by positive integral powers of x , and subject to the condition

$$(\theta_1 x)^2 (\phi_1 x) - (\theta_2 x)^2 (\phi_2 x) = P_\mu (x - x_\mu) \dots \dots (D),$$

$P_\mu (x - x_\mu)$ representing the product of the μ factors $(x - x_1) (x - x_2) (x - x_3) \dots (x - x_\mu)$,

Then
$$\Sigma \pm \psi x = C \frac{1}{x} \frac{\Psi x f x}{(x-\alpha)} - \Psi \alpha f \alpha + C \dots \dots (11),$$

where
$$\Psi x = \frac{1}{\sqrt{\phi x}} \log \left\{ \frac{\theta_1 x \sqrt{\phi_1 x} + \theta_2 x \sqrt{\phi_2 x}}{\theta_1 x \sqrt{\phi_1 x} - \theta_2 x \sqrt{\phi_2 x}} \right\} \dots \dots (E),$$

and $C \frac{1}{x} \left\{ \frac{\psi x f x}{(x-\alpha)} \right\}$ is put to represent the coefficient of $\frac{1}{x}$ in the expansion of $\frac{\Psi x f x}{x-\alpha}$, according to the negative powers of x . This is the celebrated theorem of ABEL.

Let

$$\theta_1 x = a_1 + b_1 x + c_1 x^2 + \dots + l_1 x^{m_1}$$

$$\theta_2 x = a_2 + b_2 x + c_2 x^2 + \dots + l_2 x^{m_2}.$$

By substituting these values of $\theta_1 x$ and $\theta_2 x$ in equation (D), and equating like powers of x , equations will be obtained establishing certain relations between the $m_1 + m_2 + 2$ quantities $a_1 b_1 c_1 \dots a_2 b_2 c_2 \dots$, and the μ quantities $x_1 x_2 \dots$; and if the dimensions $m_1 m_2, n_1 n_2$ be properly assumed in respect to μ , the values of these quantities will be determined in terms of $x_1 x_2 \dots$, and there will remain certain equations of condition between these quantities themselves, further necessary to the relation (D), which has been supposed.

Let one or more of the quantities $x_1 x_2 \dots$ be conceived to be variable; and assume the variable element of the polynomial $(\theta_1 x)^2 (\phi_1 x) - (\theta_2 x)^2 (\phi_2 x)$, which results from this supposition, to enter into it under the form of a function of y . Moreover, let the polynomial itself be represented under these circumstances by Φxy .

If, then, x be supposed to represent one of the quantities $x_1 x_2 x_3 \dots$ $\Phi xy = 0$;

$$\therefore \frac{d\Phi xy}{dx} dx + \frac{d\Phi xy}{dy} dy = 0 \dots \dots (F).$$

Now

$$\frac{d\Phi xy}{dy} dy = 2(\phi_1 x)(\theta_1 x) \frac{d\theta_1 x}{dy} dy - 2(\phi_2 x)(\theta_2 x) \frac{d\theta_2 x}{dx} dx.$$

But since

$$(\theta_1 x)^2 (\phi_1 x) - (\theta_2 x)^2 (\phi_2 x) = 0;$$

$$\therefore \theta_1 x \sqrt{\phi_1 x} = \pm \theta_2 x \sqrt{\phi_2 x};$$

where the sign $\pm$ is to be taken according as $\theta_1 x$ and $\theta_2 x$ have for the assumed value of x the same or different signs;

$$\therefore (\theta_1 x)(\phi_1 x) = \pm \theta_2 x \sqrt{\phi_1 x \phi_2 x} = \pm \theta_2 x \sqrt{\phi x}$$

$$(\theta_2 x)(\phi_2 x) = \pm \theta_1 x \sqrt{\phi_1 x \phi_2 x} = \pm \theta_1 x \sqrt{\phi x};$$

$$\therefore \frac{d\Phi xy}{dy} dy = \pm 2\sqrt{\phi x} \left\{ \theta_2 x \frac{d\theta_1 x}{dy} - \theta_1 x \frac{d\theta_2 x}{dy} \right\} dy \dots \dots (G);$$

Hence, reducing and assuming by equation (8.),

$$\sin \Psi_1 = \frac{\sin \theta \cos \phi_3 \Delta \phi_3 - \sin \phi_3 \cos \theta \Delta \theta}{1 - k^2 \sin^2 \theta \sin^2 \phi_3}$$

$$\sin \Psi_2 = \frac{\sin \theta \cos \phi_3 \Delta \phi_3 + \sin \phi_3 \cos \theta \Delta \theta}{1 - k^2 \sin^2 \theta \sin^2 \phi_3},$$

we have

$$\Phi = \frac{1}{2} \frac{\tan \theta}{\Delta \theta} \log \left\{ \frac{1 + k^2 \sin \theta \sin \Psi_1 \sin \phi_1 \sin \phi_2}{1 + k^2 \sin \theta \sin \Psi_2 \sin \phi_1 \sin \phi_2} \right\};$$

where, it will be observed, that the subsidiary angles, Ψ_1 and Ψ_2 , are the amplitudes of functions which satisfy the conditions

$$F\theta - F\phi_3 - F\Psi_1 = 0,$$

$$F\theta + F\phi_3 - F\Psi_2 = 0.$$

Since irrational quantities of the form $\sqrt{-1} \tan^{-1} \sqrt{-1} \Psi$ may be immediately converted into logarithmic functions, it is considered unnecessary to write the relation of three functions of the third order under any other form than that given in the text.

Definite
Integrals.

∴ by (F),

$$\frac{d\Phi xy}{dx} dx = \pm 2\sqrt{\phi x} \left\{ \theta_1 x \frac{d\theta_2 x}{dy} - \theta_2 x \frac{d\theta_1 x}{dy} \right\} dy;$$

$$\therefore \frac{\pm f x \cdot dx}{(x-\alpha) \sqrt{\phi x}} = \frac{2fx}{(x-\alpha) \frac{d\Phi xy}{dx}} \cdot \left\{ \theta_1 x \frac{d\theta_2 x}{dy} - \theta_2 x \frac{d\theta_1 x}{dy} \right\} dy.$$

In this expression x represents any one of the quantities $x_1, x_2, \dots, x_p$. Let it be made in succession to represent each of them, and let the sum of the formulæ which result from this substitution be taken;

$$\therefore \sum \frac{\pm d\psi x}{dy} = \sum \frac{2fx}{(x-\alpha) \frac{d\Phi xy}{dx}} \left\{ \theta_1 x \frac{d\theta_2 x}{dy} - \theta_2 x \frac{d\theta_1 x}{dy} \right\} \dots \dots \dots (H).$$

Let

$$2fx \cdot \left\{ \theta_1 x \frac{d\theta_2 x}{dy} - \theta_2 x \frac{d\theta_1 x}{dy} \right\} = \Lambda xy,$$

where Λxy is a polynomial ascending by positive integral powers of x , having for certain of their coefficients functions of y .

We may assume

$$\Lambda xy = \Lambda \alpha y + (x-\alpha) \Lambda_1 xy \dots \dots \dots (I).$$

By (H), therefore,

$$\sum \pm \frac{d\psi x}{dy} = \Lambda \alpha y \cdot \sum \frac{1}{(x-\alpha) \frac{d\Phi xy}{dx}} + \sum \frac{\Lambda_1 xy}{\frac{d\Phi xy}{dx}} \dots \dots \dots (K).$$

Now

$$\Phi xy = (x-x_1)(x-x_2)(x-x_3) \dots (x-x_p);$$

therefore*

$$\frac{1}{\Phi xy} = \sum \frac{1}{(x-x_n) \frac{d\Phi x_n y}{dx_n}} \dots \dots \dots (L);$$

$$\therefore \frac{1}{\Phi \alpha y} = \sum \frac{1}{(\alpha-x_n) \frac{d\Phi x_n y}{dx_n}};$$

$$\therefore \sum \pm \frac{d\psi x}{dy} = -\frac{\Lambda \alpha y}{\Phi \alpha y} + \sum \frac{\Lambda_1 xy}{\frac{d\Phi xy}{dy}} \dots \dots \dots (M).$$

It remains now to determine the value of the last term of this equation. Expanding $\frac{1}{x-x_n}$, or $\frac{1}{x} \left(1 - \frac{x_n}{x}\right)^{-1}$ in each term of the second member of equation (L),

$$\begin{aligned} \frac{1}{\Phi xy} &= \frac{1}{x} \sum \frac{1}{\frac{d\Phi x_n y}{dx_n}} + \frac{1}{x^2} \sum \frac{x_n}{\frac{d\Phi x_n y}{dx_n}} + \frac{1}{x^3} \sum \frac{x_n^2}{\frac{d\Phi x_n y}{dx_n}} + \dots \dots \dots + \frac{1}{x^{m+1}} \sum \frac{x_n^m}{\frac{d\Phi x_n y}{dx_n}} + \dots \\ \therefore \frac{x^m}{\Phi xy} &= \dots \dots \dots + \frac{1}{x} \sum \frac{x_n^m}{\frac{d\Phi x_n y}{dx_n}} + \dots \end{aligned}$$

Assuming in this equation for m the different values of the exponents of x in the terms of $\Lambda_1 xy$ successively, multiplying the equations which thus result by the respective coefficients of those terms, and adding

$$\frac{\Lambda_1 xy}{\Phi xy} = \dots \dots \dots + \frac{1}{x} \sum \frac{\Lambda_1 x_n y}{\frac{d\Phi x_n y}{dx_n}} + \dots \dots \dots$$

Thus, then, the last term of equation (M) is the coefficient of $\frac{1}{x}$ in the expansion of $\frac{\Lambda_1 xy}{\Phi xy}$, or

* Let

$A_1, A_2, \dots$ being independent of x ;

$$\frac{1}{\Phi xy} = \frac{A_1}{x-x_1} + \frac{A_2}{x-x_2} + \frac{A_n}{x-x_n} \dots \dots \dots \frac{A_p}{x-x_p},$$

$$\therefore A_n = \frac{x_n - x_n}{\frac{d\Phi x_n y}{dx_n}} = \frac{1}{\frac{d\Phi x_n y}{dx_n}};$$

$$\therefore \frac{1}{\Phi xy} = \sum \frac{1}{(x-x_n) \frac{d\Phi x_n y}{dx_n}}.$$

Definite
Integrals.Definite
Integrals.

$$\sum \frac{\Lambda_1 xy}{d\Phi xy} = C^{\frac{1}{2}} \frac{\Lambda_1 xy}{\Phi xy};$$

$$\therefore \text{by (I),} \quad \sum \frac{\Lambda_1 xy}{d\Phi xy} = C^{\frac{1}{2}} \left\{ \frac{\Lambda xy}{(x-\alpha)\Phi xy} - \frac{\Lambda \alpha y}{(x-\alpha)\Phi xy} \right\}.$$

Now the least negative exponent in the expansion of $\frac{\Lambda \alpha y}{(x-\alpha)\Phi xy}$ is $\mu+1$, the highest positive exponent in Φxy being μ . No portion of the coefficient of $\frac{1}{x}$ is therefore found in this term of the expression;

$$\therefore \sum \frac{\Lambda_1 xy}{d\Phi xy} = C^{\frac{1}{2}} \frac{\Lambda xy}{(x-\alpha)\Phi xy};$$

$$\therefore \text{by (M)} \quad \sum \pm \frac{d\psi x}{dy} = C^{\frac{1}{2}} \frac{\Lambda xy}{(x-\alpha)\Phi xy} - \frac{\Lambda \alpha y}{\Phi \alpha y}.$$

which expression, it will be observed, does not involve x . Also

$$\frac{\Lambda \alpha y}{\Phi \alpha y} = 2f\alpha \cdot \frac{\theta_1 \alpha \cdot \frac{d\theta_2 \alpha}{dy} - \theta_2 \alpha \cdot \frac{d\theta_1 \alpha}{dy}}{(\phi_1 \alpha)(\theta_1 \alpha)^2 - \phi_2 \alpha \cdot (\theta_2 \alpha)^2},$$

in which expression $f\alpha$, $\phi_1 \alpha$, $\phi_2 \alpha$ do not involve y ;

$$\therefore \int \frac{\Lambda \alpha y}{\Phi \alpha y} dy = \frac{f\alpha}{\sqrt{\phi \alpha}} \log \left\{ \frac{\theta_1 \alpha \sqrt{\phi_1 \alpha} + \theta_2 \alpha \sqrt{\phi_2 \alpha}}{\theta_1 \alpha \sqrt{\phi_1 \alpha} - \theta_2 \alpha \sqrt{\phi_2 \alpha}} \right\};$$

also

$$\int C^{\frac{1}{2}} \frac{\Lambda xy dy}{(x-\alpha)\Phi xy} = C^{\frac{1}{2}} \frac{fx}{(x-\alpha)\sqrt{\phi x}} \log \left\{ \frac{\theta_1 x \sqrt{\phi_1 x} + \theta_2 x \sqrt{\phi_2 x}}{\theta_1 x \sqrt{\phi_1 x} - \theta_2 x \sqrt{\phi_2 x}} \right\};$$

both these integrations being made in respect to y , which is independent of x .

$$\text{By equation (H)} \quad \therefore \sum \pm \psi x = C^{\frac{1}{2}} \left\{ \frac{\Psi x \cdot fx}{x-\alpha} \right\} - \Psi \alpha f\alpha + C.$$

Of this beautiful theorem a very remarkable feature is the arbitrary character of the functions $\theta_1 x$ and $\theta_2 x$, resulting in an arbitrary superior limit of the number μ of the functions included under the symbol Σ . The further discussion of it will be reserved for that portion of this paper which treats of the theory of ultra-elliptic functions, and we shall here confine ourselves to two of the most elementary applications.

EXAMPLE 1. Let

$$fx = (x-\alpha)$$

$$\phi x = (1-x^2)(1-k^2 x^2);$$

$$\therefore \psi x = \int \frac{dx}{(1-x^2)^{\frac{1}{2}}(1-k^2 x^2)^{\frac{1}{2}}};$$

or if $x = \sin \phi$,

In this case

$$\psi x = Fk\phi.$$

$$f\alpha = \alpha - \alpha = 0,$$

$\therefore$ by Abel's theorem

$$\sum \pm \psi x = C^{\frac{1}{2}} \Psi x + C \dots \dots \dots (a).$$

Now in this case it is easily seen that

$$C^{\frac{1}{2}} \Psi x = 0.*$$

$$\therefore \sum \pm Fk\phi = C \dots \dots \dots (b).$$

Let

$$\phi_1 x = 1 - x^2$$

$$\phi_2 x = 1 - k^2 x^2$$

$$\theta_1 x = a_1 + b_1 x$$

$$\theta_2 x = a_2 + b_2 x$$

$$\mu = 4;$$

$$\text{By equation (D)} \quad \therefore (a_1 + b_1 x)^2 (1-x^2) - (a_2 + b_2 x)^2 (1-k^2 x^2) = P_4(x - \sin \phi) \dots \dots \dots (c).$$

Assuming in equation (c)

$$x = 1 \quad x = -1$$

$$x = \frac{1}{k} \quad x = -\frac{1}{k}$$

* The conditions on which the evanescence of this term depends will be found fully discussed in the tenth section of this Article.

Definite Integrals. we have

Definite Integrals.

$$\begin{aligned} -(a_2 + b_2)^2 k'^2 &= P_4 (1 - \sin \phi) \\ -(a_2 - b_2)^2 k'^2 &= P_4 (1 + \sin \phi) \\ -(b_1 + a_1 k)^2 k'^2 &= P_4 (1 - k \sin \phi) \\ -(b_1 - a_1 k)^2 k'^2 &= P_4 (1 + k \sin \phi); \\ \therefore (a_2^2 - b_2^2) k'^2 &= \pm P_4 \cos \phi \\ (b_1^2 - a_1^2 k^2) k'^2 &= \pm P_4 \Delta \phi. \end{aligned}$$

Also equating the coefficients of x^4 and x^0 in (c),

$$\begin{aligned} -b_1^2 + b_2^2 k^2 &= 1 \\ a_1^2 - a_2^2 &= P_4 \sin \phi; \\ \therefore \pm k^2 P_4 \cos \phi \pm P_4 \Delta \phi &= \{b_1^2 + a_2^2 k^2 - (a_1^2 + b_2^2) k^2\} k'^2 \\ 1 + k^2 P_4 \sin \phi &= -\{b_1^2 + a_2^2 k^2 - (a_1^2 + b_2^2) k^2\}; \\ \therefore \mp P_4 \Delta \phi \mp k^2 P_4 \cos \phi &= k'^2 + k'^2 k^2 P_4 \sin \phi. \end{aligned}$$

Now in the first term of this equation the sign $+$ must be taken, since the whole of the first member has the same sign with that term, and since moreover the second member of the equation is essentially positive;

$$\therefore P_4 \Delta \phi = k'^2 + k'^2 k^2 P_4 \sin \phi \pm k^2 P_4 \cos \phi \dots \dots \dots (d),$$

which is the equation of condition annexed to the relation

$$F\phi_1 + F\phi_2 + F\phi_3 + F\phi_4 = C.*$$

To determine the constant, suppose $\phi_1 = \phi_2 = \phi_3 = \frac{\pi}{2}$, then will the equation of condition (d) be satisfied if we assume $\phi_4 = -\frac{\pi}{2}$.

Since, then, the values $\frac{\pi}{2}, \frac{\pi}{2}, \frac{\pi}{2}, -\frac{\pi}{2}$ satisfy the equation (c);

$$\therefore F\frac{\pi}{2} + F\frac{\pi}{2} + F\frac{\pi}{2} - F\frac{\pi}{2} = C;$$

$$\therefore C = 2F\frac{\pi}{2};$$

$$\therefore F\phi_1 + F\phi_2 + F\phi_3 + F\phi_4 = 2F\frac{\pi}{2} \dots \dots \dots (e).$$

EXAMPLE 2. Let

$$\begin{aligned} fx &= (x - \alpha)(1 - k^2 x^2) \\ \phi x &= (1 - x^2)(1 - k^2 x^2); \\ \therefore \psi x &= \int \frac{(1 - k^2 x^2)^{\frac{1}{2}} dx}{(x - \alpha)^{\frac{1}{2}}} = Ek\phi, \end{aligned}$$

In this case, as before, $f\alpha = 0$;

$$\therefore \frac{\Psi x fx}{x - \alpha} = (1 - k^2 x^2) \Psi x;$$

$\therefore$ by Abel's theorem,

$$\Sigma \pm \psi x = C \frac{1}{x} \{1 - k^2 x^2\} \Psi x + C \dots \dots \dots (f).$$

Assume

$$\begin{aligned} \theta_1 x &= a_1 + b_1 x \\ \theta_2 x &= a_2 + b_2 x \\ \phi_1 x &= (1 - x^2) \\ \phi_2 x &= (1 - k^2 x^2) \\ u &= 3. \end{aligned}$$

Let

$$x = \frac{1}{x'}.$$

$$\therefore \{1 - k^2 x^2\} \Psi x = \left\{ \frac{1 - x'^2}{k^2 - x'^2} \right\}^{\frac{1}{2}} \log \left\{ \frac{1 + \left(\frac{b_2 + a_2 x'}{b_1 + a_1 x'} \right) \left(\frac{k^2 - x'^2}{1 - x'^2} \right)^{\frac{1}{2}}}{1 - \left(\frac{b_2 + a_2 x'}{b_1 + a_1 x'} \right) \left(\frac{k^2 - x'^2}{1 - x'^2} \right)^{\frac{1}{2}}} \right\};$$

* Let ϕ_3 and ϕ_4 become negative, the equation of condition (d) will then remain unchanged, and $F\phi_1 + F\phi_2 - F\phi_3 - F\phi_4 = C$. Suppose $\phi_4 = 0$; $\therefore F\phi_1 + F\phi_2 - F\phi_3 = 0$, and $P_3 \Delta \phi = k'^2 + k'^2 P_3 \cos \phi$, which agrees with equation 11, page 495. It will be observed that in equation (e) the ambiguous sign of equation (b) is taken positively: this assumption will be found discussed in a Note at the end of the Article.

Definite
Integrals.

 Definite
Integrals.

$$\begin{aligned} \therefore C^{\frac{1}{2}} \{1 - k^2 x^2\} \Psi x &= k C^{\frac{1}{2}} \log. \left\{ \frac{1 + \left(\frac{b_2 + a_2 x'}{b_1 + a_1 x'} \right) k}{1 - \left(\frac{b_2 + a_2 x'}{b_1 + a_1 x'} \right) k} \right\} \\ &= k C^{\frac{1}{2}} \log. \left\{ \frac{1 + \left(\frac{a_1 + a_2 k}{b_1 + b_2 k} \right) x'}{1 + \left(\frac{a_1 - a_2 k}{b_1 - b_2 k} \right) x'} \right\} \\ &= k \left\{ \left(\frac{a_1 + a_2 k}{b_1 + b_2 k} \right) - \left(\frac{a_1 - a_2 k}{b_1 - b_2 k} \right) \right\}; \\ \therefore C^{\frac{1}{2}} \{1 - k^2 x^2\} \Psi x &= k^2 \frac{2(a_1 b_2 - a_2 b_1)}{b_1^2 - b_2^2 k^2}. \end{aligned}$$

Now by Example 1, page (503.), $b_1^2 - b_2^2 k^2 = -1$. Also if $\phi_4 = 0$, $a_1^2 - a_2^2 = 0$;

$$\therefore a_1 b_2 - a_2 b_1 = -(a_1 b_1 - a_2 b_2);$$

and equating the coefficients of x^2 in equation (c), $2(a_1 b_1 - a_2 b_2) = -P_3 \sin \phi$;

$$\therefore C^{\frac{1}{2}} \{1 - k^2 x^2\} \Psi x = k^2 P_3 \sin \phi;$$

$$\therefore E\phi_1 + E\phi_2 - E\phi_3 = C + k^2 P_3 \sin \phi,$$

which agrees with equation 3, page 496.

SECTION III.

ON THE GENERAL RELATIONS OF ELLIPTIC FUNCTIONS WHICH HAVE DIFFERENT MODULI.

It is proposed in this section to investigate the relation of the amplitudes ϕ and Φ , and the moduli k and K of two functions; such that

$$Fk\phi = \mu FK\Phi \dots \dots (12.),$$

where μ is a constant quantity.

Let

$$\sin \phi = x \quad \sin \Phi = X$$

$$\chi_{kx} = \int \frac{dx}{(1-x^2)^{\frac{1}{2}}(1-k^2 x^2)^{\frac{1}{2}}} \quad \chi_{KX} = \int \frac{dX}{(1-X^2)^{\frac{1}{2}}(1-K^2 X^2)^{\frac{1}{2}}};$$

$$\therefore \chi_{kx} = \mu \chi_{KX} \dots \dots (N).$$

1. The relation $d\chi_{kx} = \mu d\chi_{KX}$ admits of the double substitution of $\frac{1}{kx}$ for x , and $\frac{1}{KX}$ for X .

For

$$\begin{aligned} d\chi_k \frac{1}{kx} &= \frac{-\frac{dx}{kx^2}}{\left(1 - \frac{1}{k^2 x^2}\right)^{\frac{1}{2}} \left(1 - \frac{k^2}{k^2 x^2}\right)^{\frac{1}{2}}} \\ &= \frac{-dx}{(1-x^2)^{\frac{1}{2}}(1-k^2 x^2)^{\frac{1}{2}}}. \end{aligned}$$

Similarly,

$$\begin{aligned} d\chi_K \frac{1}{KX} &= \frac{-dX}{(1-X^2)^{\frac{1}{2}}(1-K^2 X^2)^{\frac{1}{2}}}; \\ \therefore d\chi_k \frac{1}{kx} &= \mu d\chi_K \frac{1}{KX}. \end{aligned}$$

2. This condition of the double substitution of $\frac{1}{kx}$ and $\frac{1}{KX}$ for x and X extends to the integral

$$\chi_{kx} = \mu \chi_{KX}.$$

For let this integral solved with respect to x be represented by $x = \theta X$, $\therefore$ substituting, $d\chi_k \theta X = \mu d\chi_K$. And this is true for all values of X ;

$$\therefore d\chi_k \theta \frac{1}{KX} = \mu d\chi_K \frac{1}{KX};$$

$$\therefore d\chi_k \theta \frac{1}{KX} = d\chi_k \frac{1}{kx};$$

$$\therefore \frac{1}{kx} = \theta \frac{1}{KX}.$$

3. Let

$$\theta X = \mu X \left(\frac{1-X^2}{1-K^2 X^2} \right)^{\frac{1}{2}},$$

then will the equation $x = \theta X$ be subject to the condition of the double substitution, provided that

Definite
Integrals.Definite
Integrals.

for

$$\mu = \frac{K}{\sqrt{k}} \dots \dots \dots (O)$$

$$\begin{aligned} \theta \frac{1}{KX} &= \frac{\mu}{KX} \left(\frac{1 - \frac{1}{K^2 X^2}}{1 - \frac{K^2}{X^2}} \right)^{\frac{1}{2}} \\ &= \frac{\mu}{K^2 X} \left(\frac{1 - K^2 X^2}{1 - X^2} \right)^{\frac{1}{2}}. \end{aligned}$$

But by (O)

$$\begin{aligned} \frac{\mu}{K^2} &= \frac{1}{\mu k}; \\ \therefore \theta \frac{1}{KX} &= \frac{1}{\mu k X} \left(\frac{1 - K^2 X^2}{1 - X^2} \right)^{\frac{1}{2}} \\ &= \frac{1}{k \theta K X} \\ &= \frac{1}{k x}. \end{aligned}$$

4. The equation

$$x = \frac{KX}{\sqrt{k}} \left(\frac{1 - X^2}{1 - K^2 X^2} \right)^{\frac{1}{2}} \dots \dots \dots (P)$$

thus satisfying one condition necessary to the relation $d\chi kx = \mu d\chi KX$, let it be required to determine whether any and what other conditions are necessary to that relation.

Squaring equation (P), and transposing

$$\begin{aligned} K^4 X^4 - (1 + kx^2) K^2 X^2 + kx^2 &= 0 \dots \dots \dots (Q); \\ \therefore \text{differentiating} \quad \{2X^2 - (kx^2 + 1)\} K^2 X dX &+ \{1 - K^2 X^2\} kx dx = 0; \\ \therefore \frac{K^2}{k} \frac{XdX}{x(1 - K^2 X^2)} + \frac{xdx}{2X^2 - (kx^2 + 1)} &= 0; \end{aligned}$$

but by (Q),

$$2X^2 - (kx^2 + 1) = - \left\{ (1 + kx^2)^2 - \frac{4kx^2}{K^2} \right\}.$$

Substituting this value and that of $\frac{X}{x}$,

$$\therefore \frac{K}{\sqrt{k}} \frac{dX}{(1 - x^2)^{\frac{1}{2}} (1 - K^2 X^2)^{\frac{1}{2}}} - \frac{dx}{\left\{ 1 + 2 \left(k - \frac{2k}{K^2} \right) x^2 + k^2 x^4 \right\}^{\frac{1}{2}}} = 0.$$

Now

$$1 + 2 \left(k - \frac{2k}{K^2} \right) x^2 + k^2 x^4 = (1 - x^2) (1 - k^2 x^2),$$

if

$$-2 \left(k - \frac{2k}{K^2} \right) = 1 + k^2;$$

or if

$$K = \frac{2\sqrt{k}}{1 + k} \dots \dots \dots (R).$$

This condition being satisfied then, we have $\mu d\chi KX - d\chi kx = 0$. Thus then it appears on the whole that to the relation $\chi kx = \mu \chi KX$ the conditions (P) and (R) are sufficient. The equations (N), (P), and (R) may be otherwise written thus:

$$\left. \begin{aligned} Fk\phi &= KFK\Phi \\ \sin \phi &= \frac{\sin 2\Phi}{(1 + k) \Delta K\Phi} \\ K &= \frac{2\sqrt{k}}{1 + k} \end{aligned} \right\} \dots \dots \dots (13.)$$

5. The relation (P) is not the only one which will satisfy the condition of the double substitution.

If $\mathbf{P} \left\{ \frac{1 - \frac{x^2}{c_n^2}}{1 - k^2 c_n^2 x^2} \right\}^m$ represent the product of any number of factors obtained by giving different values to the index n of the constant entering into the formulæ enclosed within the brackets, and any value or values whatever whole fraction positive or negative to the exponent m .

Then will

$$X = \frac{x}{\mu} \mathbf{P} \left\{ \frac{1 - \frac{x^2}{c_n^2}}{1 - k^2 c_n^2 x^2} \right\}^m \dots \dots \dots (S)$$

Definite Integrals. satisfy the condition of the double substitution, provided there be given to the constant μ a certain value dependent upon the values of K, k, c, m .
Let this function of x be represented by θx ;

Definite Integrals.

$$\begin{aligned}\therefore \theta \frac{1}{kx} &= \frac{1}{\mu kx} \mathbf{P} \left\{ \frac{1 - \frac{1}{k^2 c_n^2 x^2}}{1 - \frac{k^2 c_n^2}{x^2}} \right\}^m \\ \theta \frac{1}{kx} &= \frac{1}{\mu kx} \mathbf{P} \left\{ \frac{1}{k^2 c_n^4} \right\}^m \left\{ \frac{1 - k^2 c_n^2 x^2}{1 - \frac{x^2}{c_n^2}} \right\}^m \\ &= \frac{1}{\mu^2 k} \mathbf{P} \left\{ \frac{1}{k^2 c_n^4} \right\}^m \frac{\mu}{x} \mathbf{P} \left\{ \frac{1 - k^2 c_n^2 x^2}{1 - \frac{x^2}{c_n^2}} \right\} \\ &= \frac{K}{\mu^2 k} \mathbf{P} \left\{ \frac{1}{k^2 c_n^4} \right\}^m \cdot \frac{1}{KX}.\end{aligned}$$

The condition of the double substitution holds therefore, provided*

$$\frac{K}{\mu^2 k} \mathbf{P} \left\{ \frac{1}{k^2 c_n^4} \right\}^m = 1 \dots \dots \dots (T).$$

To determine therefore the required relation between X and x , to this general form of which we are directed by the condition of the double substitution, all that is required is to assign to the constants c_n and to the exponent m in the product (S) such values as shall cause the value of X expressed by that product to satisfy the other conditions of the equation $d\chi kx = \mu d\chi KX$.

THE THEOREM OF JACOBI.

6. Now this will be the case, 1st, if we assume m equal to unity and $c_n = \sin \operatorname{am} \frac{4n}{p} F_1$, where $\operatorname{am} \frac{4n}{p} F_1$ represents the amplitude of a function equal to the fraction $\frac{4n}{p}$ of the complete function F_1 or $Fk \frac{\pi}{2}$; and 2dly, if we take the number of factors under the symbol $\mathbf{P}$ to be $\frac{p-1}{2}$, the values of n ascending from 1 to $\frac{p-1}{2}$.
These substitutions being made, equation (S) will become

$$X = \frac{x}{\mu} \mathbf{P} \left\{ \frac{1 - \frac{x^2}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}}{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1} \right\} \dots \dots \dots (14.),$$

from which equation the following is deducible,†

$$\mu = (-1)^{\frac{p-1}{2}} \mathbf{P} \left\{ \frac{\sin \operatorname{coam} \frac{4n}{p} F_1}{\sin \operatorname{am} \frac{4n}{p} F_1} \right\}^2 \dots \dots \dots (15.);$$

whence, by elimination in (T), $K = k^p \mathbf{P} \left\{ \sin \operatorname{coam} \frac{4n}{p} F_1 \right\}^4 \dots \dots \dots (16.).$

* It will be remembered that the symbol $\mathbf{P}$ indicates here, as before, the product of any number of the factors included between the brackets or of any powers or roots of any of them.

† It will hereafter be shown, that when $x=1$, $X=1$; $\therefore$ by equation (14.),

$$\mu = \mathbf{P} \left\{ \frac{1 - \frac{1}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}}{1 - k^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1} \right\}.$$

Also by equation (2.) and (7.), assuming $\phi_3 = \frac{\pi}{2}$ and $\phi_2 = \operatorname{am} \frac{4n}{p} F_1$, $\sin^2 \operatorname{coam} \frac{4n}{p} F_1 = \frac{1 - \sin^2 \operatorname{am} \frac{4n}{p} F_1}{1 - k^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1}$;

$$\therefore \mu = (-1)^{\frac{p-1}{2}} \mathbf{P} \frac{\sin^2 \operatorname{coam} \frac{4n}{p} F_1}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}.$$

Definite
Integrals.

This is the celebrated theorem of Jacobi.

LEMMA I.

$$\sin \operatorname{am} \left\{ Fk\phi \pm 2mFk \frac{\pi}{2} \right\} = (-1)^m \sin \operatorname{am} Fk\phi$$

$$\cos \operatorname{am} \left\{ Fk\phi \pm 2mFk \frac{\pi}{2} \right\} = (-1)^m \cos \operatorname{am} Fk\phi.$$

Let

$$\operatorname{am} \left\{ Fk\phi \pm 2mFk \frac{\pi}{2} \right\} = \phi_1;$$

$$\therefore Fk\phi \pm 2mFk \frac{\pi}{2} = Fk\phi_1.$$

Now

$$\frac{1}{\Delta\phi} = \frac{1}{\Delta\left(\phi + 2m \frac{\pi}{2}\right)};$$

therefore, by a known property of periodical definite integrals (see Theorem II.)

$$2mFk \frac{\pi}{2} = Fkm\pi;$$

$$\therefore Fk\phi \pm Fkm\pi = Fk\phi_1;$$

$$\sin \phi_1 = (-1)^m \sin \phi,$$

$$\cos \phi_1 = (-1)^m \cos \phi.$$

 $\therefore$ by equation (8.)

by equation (9.)

LEMMA II. Let

$$Fk\phi_1 + Fk\phi_2 = Fk\sigma_1$$

$$Fk\phi_1 - Fk\phi_2 = Fk\sigma_2;$$

 $\therefore$ by equation (8.)

$$\sin \sigma_1 + \sin \sigma_2 = \frac{2 \sin \phi_1 \cos \phi_2 \Delta\phi_2}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2}$$

$$\sin \sigma_1 \sin \sigma_2 = \frac{\sin^2 \phi_1 - \sin^2 \phi_2}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2} \dots \dots \dots (U);$$

$$\therefore (1 \mp \sin \sigma_1) (1 \mp \sin \sigma_2) = \frac{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2 + \sin^2 \phi_1 - \sin^2 \phi_2 \mp 2 \sin \phi_1 \cos \phi_2 \Delta\phi_2}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2}.$$

Let ϕ'_2 be the coamplitude of $Fk\phi$; $\therefore$ by equation (8.)

$$\sin \phi_2 = \frac{\cos \phi'_2}{\Delta\phi'_2}, \quad \cos \phi_2 = k' \frac{\sin \phi'_2}{\Delta\phi'_2};$$

$$k' = (\Delta\phi_2) (\Delta\phi'_2).$$

and $\therefore$

Substituting these values, and reducing,

$$(1 \mp \sin \sigma_1) (1 \mp \sin \sigma_2) = \frac{k'^2 \{ \sin \phi'_2 \mp \sin \phi_1 \}^2}{(\Delta\phi'_2)^2 \{ 1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2 \}};$$

$$\therefore \frac{(1 \mp \sin \sigma_1) (1 \mp \sin \sigma_2)}{\cos^2 \phi_2} = \frac{\left\{ 1 \mp \frac{\sin \phi_1}{\sin \phi'_2} \right\}^2}{1 - k^2 \sin^2 \phi_1 \sin^2 \phi_2} \dots \dots \dots (V).$$

Let now

$$\phi_1 = \operatorname{am} F, \quad \phi_2 = \operatorname{am} \frac{4n}{p} F_1; \quad \therefore \phi'_2 = \operatorname{coam} \frac{4n}{p} F_1$$

$$\sigma_1 = \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \quad \sigma_2 = \operatorname{am} \left(F - \frac{4n}{p} F_1 \right);$$

 $\therefore$ by Lemma I. $\therefore$ by equation (U)

$$\frac{\sin \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \sin \operatorname{am} \left(F + \frac{4(p-n)}{p} F_1 \right)}{-\sin^2 \operatorname{am} \frac{4n}{p} F_1} = \frac{1 - \frac{\sin^2 \operatorname{am} F}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}}{1 - k^2 \sin^2 \operatorname{am} F \sin^2 \operatorname{am} \frac{4n}{p} F_1} \dots \dots \dots (W);$$

by equation (V)

$$\frac{\left\{ 1 - \sin \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \right\} \left\{ 1 - \sin \operatorname{am} \left(F + \frac{4(p-n)}{p} F_1 \right) \right\}}{\cos^2 \operatorname{am} \frac{4n}{p} F_1} = \frac{\left\{ 1 - \frac{\sin \operatorname{am} F}{\sin \operatorname{coam} \frac{4n}{p} F_1} \right\}^2}{1 - k^2 \sin^2 \operatorname{am} F \sin^2 \operatorname{am} \frac{4n}{p} F_1} \dots \dots \dots (X).$$

Definite
Integrals.

Definite Integrals.

Since $x = \sin \operatorname{am} F$, $X = \sin \operatorname{am} \frac{F}{\mu}$, we have from equations (14.) and (W.)

$$\sin \operatorname{am} \frac{F}{\mu} = \frac{\sin \operatorname{am} F}{\mu} \prod_{\frac{p-1}{2}}^1 \left\{ \frac{\sin \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \sin \operatorname{am} \left(F + \frac{4(p-n)}{p} F_1 \right)}{-\sin^2 \operatorname{am} \frac{4n}{p} F_1} \right\};$$

$\therefore$ eliminating μ by equation (15.),

$$\sin \operatorname{am} \frac{F}{\mu} = \sin \operatorname{am} F \prod_{\frac{p-1}{2}}^1 \frac{\sin \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \sin \operatorname{am} \left(F + \frac{4(p-n)}{p} F_1 \right)}{\sin^2 \operatorname{coam} \frac{4n}{p} F_1};$$

$$\therefore \text{ by equation (16.) } \sin \operatorname{am} \frac{F}{\mu} = \left(\frac{k^p}{K} \right)^{\frac{1}{2}} \prod_p^1 \sin \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \dots \dots \dots (17.).$$

Now this equation will remain unchanged if for F we substitute in the second number $F + \frac{4m}{p} F_1$, where m is any number less than $p-1$. For by this substitution each factor of the product will be advanced m in the series of factors, except the m last factors, which are

$$\sin \operatorname{am} \left(F + \frac{4(p-m+1)}{p} F_1 \right), \sin \operatorname{am} \left(F + \frac{4(p-m+2)}{p} F_1 \right) \dots \dots \sin \operatorname{am} \left(F + \frac{4(p)}{p} F_1 \right);$$

and these become, by making the proposed substitution, and reducing by the first lemma,

$$\sin \operatorname{am} \left(F + \frac{4}{p} F_1 \right), \sin \operatorname{am} \left(F + \frac{8}{p} F_1 \right) \dots \dots \sin \operatorname{am} \left(F + \frac{4(m)}{p} F_1 \right).$$

That is, they become the first m factors of the series, and complete it.

Since, then, the value of the second member of this equation is the same, whether for F we take F , or $F + \frac{4m}{p} F_1$; and since this is, moreover, true for all values of F , it follows that it is true whether for F we take 0 or $\frac{4m}{p} F_1$. But when $F=0$ the second member of the equation vanishes, therefore it vanishes when $F = \frac{4m}{p} F_1$, for all values of m included between 1 and p ; and these are all different values of F , and they are the same in number (p) as the factors of the product $\prod_p^1$

Now this being the case, it follows that another form of the above relation (17.) is the following:

$$1 - \sin \operatorname{am} \frac{F}{\mu} = \prod_p^1 \frac{1 - \sin \operatorname{am} \left(F + \frac{4n}{p} F_1 \right)}{\cos \operatorname{am} \frac{4n}{p} F_1} \dots \dots \dots (18.);$$

for, by what has been said before, the second member of this equation retains the same value if for F we substitute in it $F + \frac{4m}{p} F_1$; and this is true for all values of F , therefore it is true whether we substitute for F the values 0 or $\frac{4m}{p} F_1$. But when for F , 0 is substituted, the second member becomes

$$\begin{aligned} & \prod_p^1 \frac{1 - \sin \operatorname{am} \frac{4n}{p} F_1}{\cos \operatorname{am} \frac{4n}{p} F_1} \\ &= \prod_{\frac{p-1}{2}}^1 \frac{\left\{ 1 - \sin \operatorname{am} \frac{4n}{p} F_1 \right\} \left\{ 1 - \sin \operatorname{am} \frac{4(p-n)}{p} F_1 \right\}}{\cos \operatorname{am} \frac{4n}{p} F_1 \cos \operatorname{am} \frac{4(p-n)}{p} F_1} \\ &= \prod_{\frac{p-1}{2}}^1 \frac{\left\{ 1 - \sin \operatorname{am} \frac{4n}{p} F_1 \right\} \left\{ 1 + \sin \operatorname{am} \frac{4n}{p} F_1 \right\}}{\cos \operatorname{am} \frac{4n}{p} F_1 \cos \operatorname{am} \frac{4n}{p} F_1} \\ &= 1; \end{aligned}$$

Definite Integrals.

Definite
Integrals. $\therefore$ in this case

$$1 - \sin \operatorname{am} \frac{F}{\mu} = 1, \text{ or } \sin \operatorname{am} \frac{F}{\mu} = 0.$$

Definite
Integrals.

Since, then, in this equation $\sin \operatorname{am} \frac{F}{\mu}$ vanishes when $F=0$, it vanishes for all the p values $\frac{4m}{p} F_1$ of F , and therefore the relation (17.) and (18.) are different forms of the same relation. Now

$$\mathbf{P}_p \frac{1 - \sin \operatorname{am} \left(F + \frac{4n}{p} F_1 \right)}{\cos \operatorname{am} \frac{4n}{p} F_1} = (1 - \sin \operatorname{am} F) \mathbf{P}_{\frac{p-1}{2}} \frac{\left\{ 1 - \sin \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \right\} \left\{ 1 - \sin \operatorname{am} \left(F + \frac{4(p-n)}{p} F_1 \right) \right\}}{\cos \operatorname{am} \frac{4n}{p} F_1 \cos \operatorname{am} \frac{4(p-n)}{p} F_1};$$

 $\therefore$ by equation (X), Lemma II.,

$$1 - \sin \operatorname{am} \frac{F}{\mu} = (1 - \sin \operatorname{am} F) \mathbf{P}_{\frac{p-1}{2}} \frac{\left\{ 1 - \frac{\sin \operatorname{am} F}{\sin \operatorname{coam} \frac{4n}{p} F_1} \right\}^2}{1 - k^2 \sin^2 \operatorname{am} F \sin^2 \operatorname{am} \frac{4n}{p} F_1} \dots\dots\dots (19.),$$

or

$$1 - X = (1 - x) \mathbf{P}_{\frac{p-1}{2}} \frac{\left\{ 1 - \frac{x}{\sin \operatorname{coam} \frac{4n}{p} F_1} \right\}^2}{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1} \dots\dots\dots (20.).$$

Now by equation (14.) it appears that when X becomes $-X$, x becomes $-x$;

$$\therefore 1 + X = (1 + x) \mathbf{P}_{\frac{p-1}{2}} \frac{\left\{ 1 + \frac{x}{\sin \operatorname{coam} \frac{4n}{p} F_1} \right\}^2}{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1};$$

$$\therefore (1 - X^2) = (1 - x^2) \mathbf{P}_{\frac{p-1}{2}} \frac{\left\{ 1 - \frac{x^2}{\sin^2 \operatorname{coam} \frac{4n}{p} F_1} \right\}^2}{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1} \dots\dots\dots (Y).$$

Also when X becomes $\frac{1}{KX}$, x becomes $\frac{1}{kx}$;

$$\therefore 1 - \frac{1}{K^2 X^2} = \left(1 - \frac{1}{k^2 x^2} \right) \mathbf{P}_{\frac{p-1}{2}} \frac{\left\{ 1 - k^2 x^2 \sin^2 \operatorname{coam} \frac{4n}{p} F_1 \right\}^2}{1 - \frac{x^2}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}} \left\{ \mathbf{P}_{\frac{p-1}{2}} \frac{1}{k^4 \sin^4 \operatorname{coam} \frac{4n}{p} F_1 \sin^4 \operatorname{am} \frac{4n}{p} F_1} \right\}^2$$

But $\mathbf{P}_{\frac{p-1}{2}} k^4 \sin^4 \operatorname{coam} \frac{4n}{p} F_1 \sin^4 \operatorname{am} \frac{4n}{p} F_1 = k^{-2} \left\{ \mathbf{P}_{\frac{p-1}{2}} \sin^4 \operatorname{coam} \frac{4n}{p} F_1 \right\}^2 \left\{ \mathbf{P}_{\frac{p-1}{2}} \frac{\sin^2 \operatorname{am} \frac{4n}{p} F_1}{\sin^2 \operatorname{coam} \frac{4n}{p} F_1} \right\}^2 = \frac{K^2}{k^2 \mu^2}$

by equations (15.), (16.);

$$\therefore \frac{1 - K^2 X^2}{X^2} = \mu^2 \frac{1 - k^2 x^2}{x^2} \mathbf{P}_{\frac{p-1}{2}} \frac{\left\{ 1 - k^2 x^2 \sin^2 \operatorname{coam} \frac{4n}{p} F_1 \right\}^2}{1 - \frac{x^2}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}};$$

$$\therefore \text{by equation (15.) } 1 - K^2 X^2 = (1 - k^2 x^2) \mathbf{P}_{\frac{p-1}{2}} \frac{\left\{ 1 - k^2 x^2 \sin^2 \operatorname{coam} \frac{4n}{p} F_1 \right\}^2}{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1} \dots\dots\dots (21.);$$

 $\therefore$ by equation (Y)

Definite Integrals.

Definite Integrals.

$$(1 - K^2 X^2)(1 - X^2) = (1 - k^2 x^2)(1 - x^2) \prod_{\frac{p-1}{2}}^1 \frac{\left\{1 - k^2 x^2 \sin^2 \operatorname{coam} \frac{4n}{p} F_1\right\}^2 \left\{1 - \frac{x^2}{\sin^2 \operatorname{coam} \frac{4n}{p} F_1}\right\}^2}{\left\{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1\right\}^4}.$$

Let the numerator of the product in the second member $= M^2$, and the denominator $= N^2$;

$$\therefore (1 - K^2 X^2)(1 - X^2) = (1 - k^2 x^2)(1 - x^2) \frac{M^2}{N^2} \dots \dots (Z)$$

Let

$$X_1 = NX = \frac{x}{\mu} \prod_{\frac{p-1}{2}}^1 \left\{1 - \frac{x^2}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}\right\};$$

$$\therefore (N^2 - K^2 X_1^2)(N^2 - X_1^2) = (1 - k^2 x^2)(1 - x^2) M^2.$$

The first member of this equation is the product of the factors

$$N + KX_1 \quad N - KX_1 \quad N + X_1 \quad N - X_1,$$

which are polynomials of p dimensions, N being of $p-1$, and X_1 of p dimensions. Now these four factors have no common divisor, since N and X have none. Also their product is divisible by each of the factors

$$1 + kx \quad 1 - kx \quad 1 + x \quad 1 - x;$$

And after such division each factor becomes a square, since their product is a square M^2 ; or, in other words, each of the four factors

$$N + KX_1 \quad N - KX_1 \quad N + X_1 \quad N - X_1$$

is a square, or the product of a simple quantity and a square.

Now

$$X = \frac{X_1}{N};$$

$$\therefore N^2 \frac{dX}{dx} = N \frac{dX_1}{dx} - X_1 \frac{dN}{dx} = X_2 \text{ suppose};$$

$$\therefore X_2 = (N - AX_1) \frac{dX_1}{dx} - X_1 \frac{d(N - AX_1)}{dx},$$

where A is any constant quantity.

If, then, $N - AX_1$ have a square factor, then is X_2 divisible by the simple factor of which it is the square; X_2 is therefore divisible by all the simple quantities whose squares are factors of

$$N + KX_1 \quad N - KX_1 \quad N + X_1 \quad N - X_1.$$

But the square factors of these quantities compose by their product the square M^2 , the factors of which these are the squares compose therefore M ; X_2 is therefore divisible by M .

But X_1 being of p dimensions, and N of $p-1$ dimensions, X_2 , which equals $N \frac{dX_1}{dx} - X_1 \frac{dN}{dx}$, is of $2p-2$ dimensions: also M is of $2p-2$ dimensions; $\therefore \frac{X_2}{M}$ is of no dimension in x , or it is a constant quantity.

Let x be exceeding small; in this case

$$X_1 = \frac{x}{\mu} \quad N = 1 \quad M = 1 \quad X_2 = \frac{dX_1}{dx} = \frac{1}{\mu}; \quad \therefore \frac{X_2}{M} = \frac{1}{\mu};$$

$\therefore$ for all values of x

$$\frac{X_2}{M} = \frac{1}{\mu};$$

$$\therefore M = \mu X_2 = \mu N^2 \frac{dX}{dx}; \quad \therefore \frac{M}{N^2} = \mu \frac{dX}{dx};$$

by equation (Z)

$$\therefore \frac{(1 - K^2 X^2)^{\frac{1}{2}} (1 - X^2)^{\frac{1}{2}}}{(1 - k^2 x^2)^{\frac{1}{2}} (1 - x^2)^{\frac{1}{2}}} = \mu \frac{dX}{dx}$$

$$\therefore \frac{dx}{(1 - k^2 x^2)^{\frac{1}{2}} (1 - x^2)^{\frac{1}{2}}} = \frac{\mu dx}{(1 - K^2 X^2)^{\frac{1}{2}} (1 - X^2)^{\frac{1}{2}}}.$$

The values of X , K , μ , assumed in equations (14.), (15.), (16.), satisfy, therefore, the equation $\chi kx = \mu \chi KX$, and the demonstration of the theorem of Jacobi is thus completed.

7. There are certain other forms of equation (14.) under which it will now be convenient to place it.

By equation (14.)

$$\sin \operatorname{am} \frac{F}{\mu} = \frac{\sin \operatorname{am} F}{\mu} \prod_{\frac{p-1}{2}}^1 \left\{ \frac{1 - \frac{x^2}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}}{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1} \right\};$$

Definite
Integrals.Definite
Integrals.

and by equation (Y)

$$\cos \operatorname{am} \frac{F}{\mu} = \cos \operatorname{am} F \prod_{\frac{p-1}{2}}^1 \left\{ \frac{1 - \frac{x^2}{\sin^2 \operatorname{coam} \frac{4n}{p} F_1}}{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1} \right\}.$$

Also by Lemma II.

$$\sin \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \sin \operatorname{am} \left(F - \frac{4n}{p} F_1 \right) = - \sin^2 \operatorname{am} \frac{4n}{p} F_1 \frac{1 - \frac{x^2}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}}{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1};$$

and proceeding by a similar method to that given in Lemma II., with respect to $\cos \sigma_1$ and $\cos \sigma_2$,

$$\cos \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \cos \operatorname{am} \left(F - \frac{4n}{p} F_1 \right) = - \cos^2 \operatorname{am} \frac{4n}{p} F_1 \frac{1 - \frac{x^2}{\sin^2 \operatorname{coam} \frac{4n}{p} F_1}}{1 - k^2 x^2 \sin^2 \operatorname{am} \frac{4n}{p} F_1};$$

$$\therefore \tan \operatorname{am} \frac{F}{\mu} = \frac{\tan \operatorname{am} F}{\mu} \prod_{\frac{p-1}{2}}^1 \cot^2 \operatorname{am} \frac{4n}{p} F_1 \prod_{\frac{p-1}{2}}^1 \tan \operatorname{am} \left(F + \frac{4n}{p} F_1 \right).$$

Also by equation (21.), making $X=x=1$, since by equation (20.) these are corresponding values of X and x ,

$$K' = k' \prod_{\frac{p-1}{2}}^1 \left\{ \frac{\Delta \operatorname{coam} \frac{4n}{p} F_1}{\Delta \operatorname{am} \frac{4n}{p} F_1} \right\} = k' \prod_{\frac{p-1}{2}}^1 \frac{\left\{ \Delta \operatorname{coam} \frac{4n}{p} F_1 \right\}^{4*}}{k'^2}$$

$$K' = k' \prod_{\frac{p-1}{2}}^1 k'^2 \left\{ \frac{\sin \operatorname{coam} \frac{4n}{p} F_1}{\cos \operatorname{am} \frac{4n}{p} F_1} \right\}^4 = k'^p \prod_{\frac{p-1}{2}}^1 \left\{ \frac{\sin \operatorname{coam} \frac{4n}{p} F_1}{\sin \operatorname{am} \frac{4n}{p} F_1} \right\}^4 \prod_{\frac{p-1}{2}}^1 \left\{ \tan \operatorname{am} \frac{4n}{p} F_1 \right\}^4;$$

$$\text{by equation (15.)} \quad \therefore K' = k'^p \mu^2 \prod_{\frac{p-1}{2}}^1 \left\{ \tan \operatorname{am} \frac{4n}{p} F_1 \right\}^4; \quad \therefore \prod_{\frac{p-1}{2}}^1 \cot^2 \operatorname{am} \frac{4n}{p} F_1 = \mu \left(\frac{k'^p}{K'} \right)^{\frac{1}{2}};$$

$$\therefore \tan \operatorname{am} \frac{F}{\mu} = \left(\frac{k'^p}{K'} \right)^{\frac{1}{2}} \prod_{\frac{p-1}{2}}^1 \tan \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) \dots \dots \dots (22.);$$

$$\text{also by equation (19.)} \quad \frac{1 - \sin \operatorname{am} \frac{F}{\mu}}{1 + \sin \operatorname{am} \frac{F}{\mu}} = \frac{1 - \sin \operatorname{am} F}{1 + \sin \operatorname{am} F} \prod_{\frac{p-1}{2}}^1 \left\{ \frac{\sin \operatorname{coam} \frac{4n}{p} F_1 - \sin \operatorname{am} F}{\sin \operatorname{coam} \frac{4n}{p} F_1 + \sin \operatorname{am} F} \right\}.$$

$$\therefore \tan \frac{1}{2} \left\{ \frac{\pi}{2} - \operatorname{am} \frac{F}{\mu} \right\} = \tan \frac{1}{2} \left\{ \frac{\pi}{2} - \operatorname{am} F \right\} \prod_{\frac{p-1}{2}}^1 \frac{\tan \frac{1}{2} \left\{ \operatorname{coam} \frac{4n}{p} F_1 - \operatorname{am} F \right\}}{\tan \frac{1}{2} \left\{ \operatorname{coam} \frac{4n}{p} F_1 + \operatorname{am} F \right\}} \dots \dots \dots (23.).$$

The m th, from the termination of the series of values of the form $\sin \operatorname{am} \frac{4m}{p} F_1$, obtained by giving to m the values 1 to $\frac{p-1}{2}$, is

$$\sin \operatorname{am} \frac{4 \left\{ \frac{p-1}{2} - m - 1 \right\}}{p} F_1,$$

or it is by Lemma I.

$$- \sin \operatorname{am} \frac{2(2m-1)}{p} F_1.$$

Also the m th from the beginning of the series is

$$+ \sin \operatorname{am} \frac{2(2m)}{p} F_1.$$

These are, therefore, consecutive terms included under the form

$$(-1)^n \sin \operatorname{am} \frac{2n}{p} F_1.$$

* For the relations of the amplitude and coamplitude of a function on which these transformations depend, see Lemma II.

Definite Integrals.

Wherever, therefore, in the preceding formulæ there occur factors which differ only by values of n , ascending from 1 to $\frac{p-1}{2}$, in the form $\sin \operatorname{am} \frac{4n}{p} F$, we may substitute for this form this other, $(-1)^n \sin \operatorname{am} \frac{2n}{p} F$; and the same is true of the coamplitude. Equations (14.), (20.), (15.), (16.) thus become

Definite Integrals.

$$\begin{aligned} \sin \operatorname{am} \frac{F}{\mu} &= \frac{\sin \operatorname{am} F}{\mu} \prod_{\frac{p-1}{2}}^1 \left\{ \frac{1 - \frac{\sin^2 \operatorname{am} F}{\sin^2 \operatorname{am} \frac{2n}{p} F}}{1 - k^2 \sin^2 \operatorname{am} F \sin^2 \operatorname{am} \frac{2n}{p} F} \right\} \dots\dots\dots (A'), \\ 1 - \sin \operatorname{am} \frac{F}{\mu} &= (1 - \sin \operatorname{am} F) \prod_{\frac{p-1}{2}}^1 \left\{ \frac{1 - (-1)^n \frac{\sin \operatorname{am} F}{\sin \operatorname{coam} \frac{2n}{p} F}}{1 - k^2 \sin^2 \operatorname{am} F \sin^2 \operatorname{am} \frac{2n}{p} F} \right\} \dots\dots\dots (B'), \\ \mu &= (-1)^{\frac{p-1}{2}} \prod_{\frac{p-1}{2}}^1 \left\{ \frac{\sin \operatorname{coam} \frac{2n}{p} F}{\sin \operatorname{am} \frac{2n}{p} F} \right\} \dots\dots\dots (C'), \\ K &= k^p \prod_{\frac{p-1}{2}}^1 \left\{ \sin \operatorname{coam} \frac{2n}{p} F \right\}^4 \dots\dots\dots (D') \end{aligned}$$

8. We come now to the discussion of another class of functions, included under the form

$$\sqrt{-1} Fk\phi.$$

Functions under this imaginary form having the modulus k may be transformed into others under the form of real functions, with this difference, that the modulus which was before k will now be k' .

This transformation is the object of JACOBI'S SECOND THEOREM.

$$\text{THEOREM VIII. } \sqrt{-1} Fk\phi = \int \frac{\sqrt{-1} d\phi}{\sqrt{1 - k^2 \sin^2 \phi}} = \int \frac{\sqrt{-1} d\phi}{\sqrt{\cos^2 \phi + k'^2 \sin^2 \phi}} = \int \frac{\sqrt{-1} \frac{d\phi}{\cos \phi}}{\sqrt{1 + k'^2 \tan^2 \phi}}.$$

Let

$$\begin{aligned} \tan \phi &= \sqrt{-1} \sin \phi'; \dots\dots\dots (E'); \\ \therefore \cos \phi &= \sec \phi'; \\ \therefore d\phi &= \sqrt{-1} \frac{d\phi'}{\cos \phi}; \\ \therefore \sqrt{-1} Fk\phi &= Fk'\phi' \dots\dots\dots (F'). \end{aligned}$$

Thus, then, the imaginary function $\sqrt{-1} Fk\phi$ will become a real function $Fk'\phi'$, provided we change k into its suppléant k' , and give to ϕ' a value determined by the relation (E'). Thus then

$$\left. \begin{aligned} \sqrt{-1} \tan \operatorname{am} Fk\phi &= \sin \operatorname{am} \sqrt{-1} Fk\phi = \sin \operatorname{am} Fk'\phi' \\ \sqrt{-1} \tan \operatorname{am} \left(F + \frac{4n}{p} F_1 \right) &= \sin \operatorname{am} \left(F' + \frac{4n}{p} F'_1 \right) \end{aligned} \right\} \dots\dots\dots (G'),$$

where F' is written for $\sqrt{-1} Fk\phi$, or $Fk'\phi'$; $\therefore$ substituting in equation (22.),

$$\sin \operatorname{am} \frac{F'}{\mu} = (-1)^{\frac{p-1}{2}} \left(\frac{k'^p}{K'} \right) \prod_{\frac{p-1}{2}}^1 \sin \operatorname{am} \left(F' + \frac{4n}{p} F'_1 \right) \dots\dots\dots (24.).$$

Also

$$\begin{aligned} \sin \operatorname{coam} F &= \frac{\cos \operatorname{am} F}{\Delta \operatorname{am} F} = \frac{1}{\Delta \operatorname{am} F'}; \\ \therefore \frac{\sin \operatorname{am} F}{\sin \operatorname{coam} F} &= -\sqrt{-1} \tan \operatorname{am} F' \cdot \Delta \operatorname{am} F' = -\frac{\sqrt{-1} \sin \operatorname{am} F'}{\sin \operatorname{coam} F'}; \end{aligned}$$

by equation (15.)

$$\therefore \mu = \prod_{\frac{p-1}{2}}^1 \left\{ \frac{\sin \operatorname{coam} \frac{4n}{p} F'_1}{\sin \operatorname{am} \frac{4n}{p} F'_1} \right\} \dots\dots\dots (25.);$$

and since

$$K' = k'^p \mu^2 \prod_{\frac{p-1}{2}}^1 \left\{ \tan \operatorname{am} \frac{4n}{p} F'_1 \right\}^4;$$

$$\therefore K' = k'^p \mu^{\frac{p-1}{2}} \prod_{\frac{p-1}{2}}^1 \left\{ \sin \operatorname{am} \frac{4n}{p} F_1 \right\}^4;$$

$$\therefore K' = k'^p \prod_{\frac{p-1}{2}}^1 \left\{ \sin \operatorname{coam} \frac{4n}{p} F_1 \right\}^4 \dots \dots \dots (26.).$$

The equations (24.), (25.), (26.) serve to determine the quantities Φ' , μ , K' , in terms of ϕ' , k' , subject to the condition $Fk'\phi' = \mu FK'\Phi'$. Comparing these equations with equations (17.), (22.), (15.), (16.), it appears "that the same formulæ which serve for the transformation of a function having the modulus k into another having the modulus K , apply equally to the transformation of a function having the modulus k' into one having the modulus K' , provided that in these last F be replaced by $\frac{F'}{\sqrt{-1}}$, and μ by $(-1)^{\frac{p-1}{2}} \mu$.

These last formulæ, which serve for the transformation of functions whose moduli are complements to the moduli of the first, are called by Jacobi complementary formulæ.

9. If in equation (B') we write, after the symbol of multiplication, the n th term from the end instead of from the beginning of the series of factors, we have

$$1 - \sin \operatorname{am} \frac{F}{\mu} = (1 - \sin \operatorname{am} F) \prod_{\frac{p-1}{2}}^1 \left\{ \frac{1 - \frac{(-1)^{\frac{p-2n+1}{2}} \sin \operatorname{am} F}{\sin \operatorname{coam} \frac{p-2n+1}{p} F_1}}{1 - k^2 \sin^2 \operatorname{am} F \sin^2 \operatorname{am} \frac{p-2n+1}{p} F_1} \right\},$$

$$\text{or } 1 - \sin \operatorname{am} \frac{F}{\mu} = (1 - \sin \operatorname{am} F) \prod_{\frac{p-1}{2}}^1 \left\{ \frac{1 - \frac{(-1)^{\frac{p-2n+1}{2}} \sin \operatorname{am} F}{\sin \operatorname{am} \frac{2n-1}{p} F_1}}{1 - k^2 \sin^2 \operatorname{am} F \sin^2 \operatorname{coam} \frac{2n-1}{p} F_1} \right\} \dots \dots \dots (H').$$

$$\text{If, therefore, } (-1)^{\frac{p-2n+1}{2}} F = \frac{2n-1}{p} F_1, \quad 1 - \sin \operatorname{am} \frac{F}{\mu} = 0,$$

and this is true for all values of n , from 1 to $\frac{p-1}{2}$. Moreover, by equation (12.), $\operatorname{am} \frac{F}{\mu}$ increases with $\operatorname{am} F$, therefore when

$$(-1)^{\frac{p-1}{2}} F = +\frac{1}{p} F_1, \quad -\frac{3}{p} F_1, \quad +\frac{5}{p} F_1, \dots \dots \dots \pm \frac{p-2}{p} F_1,$$

$$(-1)^{\frac{p-1}{2}} \operatorname{am} \frac{F}{\mu} = \frac{\pi}{2}, \quad \frac{3\pi}{2}, \quad \frac{5\pi}{2}, \dots \dots \dots \frac{p-2}{p} F_1;$$

$$\therefore \frac{1}{p} F_1 k = \mu F_1 K \dots \dots \dots (27.),$$

$F_1 K$ and $F_1 k$ representing the complete functions $FK \frac{\pi}{2}$ and $Fk \frac{\pi}{2}$.

THEOREM IX.—By equations (14.) and (Y) it appears tha.

$$\tan \operatorname{am} \frac{F}{\mu} = \frac{\tan \operatorname{am} F}{\mu} \prod_{\frac{p-1}{2}}^1 \left\{ \frac{1 - \frac{\sin^2 \operatorname{am} F}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}}{1 - \frac{\sin^2 \operatorname{am} F}{\sin^2 \operatorname{coam} \frac{4n}{p} F_1}} \right\};$$

$$\therefore \sin \operatorname{am} \frac{F'}{\mu} = \frac{\sin \operatorname{am} F'}{\mu} \prod_{\frac{p-1}{2}}^1 \left\{ \frac{1 + \frac{\tan^2 \operatorname{am} F'}{\sin^2 \operatorname{am} \frac{4n}{p} F_1}}{1 + \frac{\tan^2 \operatorname{am} F'}{\sin^2 \operatorname{coam} \frac{4n}{p} F_1}} \right\}.$$

Definite
Integrals.

Let now

$$\text{am } F' = (-1)^{\frac{p-1}{2}} \frac{\pi}{2};$$

Definite
Integrals.

$$\therefore \sin \text{am } \frac{F'}{\mu} = \frac{1}{\mu} \prod_{\frac{p-1}{2}}^1 \frac{\sin^2 \text{coam } \frac{4n}{p} F_1}{\sin^2 \text{am } \frac{4n}{p} F_1} = (-1)^{\frac{p-1}{2}} \text{ by equation (15.);}$$

 $\therefore$ when

$$\text{am } F' = (-1)^{\frac{p-1}{2}} \frac{\pi}{2}, \quad \text{am } \frac{F'}{\mu} = (-1)^{\frac{p-1}{2}} \frac{\pi}{2};$$

$$\therefore F_1 k' = \mu F_1 K' \dots \dots \dots (28.);$$

by equation (27.)

$$\therefore \frac{F_1 k}{F_1 k'} = p \frac{F_1 K}{F_1 K'} \dots \dots \dots (29.).$$

By this remarkable theorem a direct relation is established between the modulus k and the modulus K of two functions, whose amplitudes are connected by the relation (14.). For a discussion of the various applications which may be made of it in the theory of elliptic functions, the reader is referred to the third Supplement of Legendre, § vii., or to the work of Jacobi—*Fundamenta nova Theoriæ functionum ellipticarum*.

SECTION IV.

ON A METHOD OF APPROXIMATING TO THE NUMERICAL VALUES OF ELLIPTIC FUNCTIONS.

From the equation

$$K = k^p \prod_{\frac{p-1}{2}}^1 \sin^4 \text{coam } \frac{2n F_1}{p}$$

it appears that since k is less than unity, therefore K is less than k .

Thus, then, the function $Fk\phi$ may be ascertained by Jacobi's first theorem in terms of another $FK\phi$, having a less modulus. This again may be made to depend upon a third, whose modulus is yet less, and so on; and thus we may, ultimately, find the value of a function in terms of another having a modulus as much less as we like.

Again, by the second theorem, the value of a function whose modulus is k' , the complement of k , is made to depend upon one whose modulus is K' , the complement of K , and since k is greater than K , therefore k' is less than K' . By this theorem, therefore, we may make the value of one function to depend upon that of another having as much greater a modulus as we like.

And in thus making the values of functions depend upon those of others whose moduli are so much less as to be considered nearly evanescent, or so much greater as to be considered nearly equal to unity, in both which cases these values may be determined by known rules, consists the method of approximating to the numerical values of elliptic functions.

The formulæ of Jacobi supply an infinite number of relations* between k and K , by means of which this may be effected, as many indeed as there may be taken odd numbers p ; and Mr. Ivory has given analogous formulæ for the case in which p is an even number in the *Philosophical Transactions*, 1831.

Of all the infinite number of scales of moduli, however, which may thus be found, there is probably none which so well serves the purposes of calculation as that which we have first investigated (art. 9. equation 13.); as moreover this scale of moduli is that by which the existing tables of elliptic functions have been calculated, we shall enter fully on the discussion of it.

The equations (13.) admit of the following transformations:

$$\left. \begin{aligned} K &= \frac{2\sqrt{k}}{1+k} & k' &= \frac{2\sqrt{K'}}{1+K'} \\ k &= \frac{1-K'}{1+K'} & K' &= \frac{1-k}{1+k} \\ (1+K')(1+k) &= 2 \end{aligned} \right\} \dots \dots \dots (K').$$

$$\left. \begin{aligned} \sin \phi &= \frac{\sin 2\Phi}{(1+k) \Delta K \Phi} \\ \sin (2\Phi - \phi) &= k \sin \phi^\dagger \\ \tan (\phi - \Phi) &= K' \tan \phi \end{aligned} \right\} \dots \dots \dots (L').$$

* These relations have been discussed by Jacobi in his work *Fundamenta Nova*, &c. for the cases $p=3$ and $p=5$; by Guetzlaff in the twelfth volume of Crelle's *Journal*, page 173, for the case of $p=7$; and in the sixteenth number of that journal, page 97, the equations of the moduli have been placed under a variety of new forms by Professor Sohnke, and applied to the values of $p, 3, 5, 7, 11, 13, 21$.

† By equation (13.)

$$\begin{aligned} \sin^2 2\Phi &= (1+k)^2 \sin^2 \phi \left\{ 1 - \frac{4k}{(1+k)^2} \sin^2 \Phi \right\} \\ \sin^2 2\Phi &= \sin^2 \phi \{ 1 + k^2 + 2k \cos 2\Phi \}; \\ \therefore \cos 2\Phi &= \cos \phi \Delta k \phi - k \sin^2 \phi \dots \dots \dots (*); \end{aligned}$$

Definite
Integrals.Definite
Integrals.

$$\left. \begin{aligned} Fk\phi &= \frac{K}{\sqrt{k}} FK\Phi \\ Fk\phi &= \frac{2}{1+k} FK\Phi \\ Fk\phi &= (1+K') FK\Phi \end{aligned} \right\} \dots\dots\dots (M').$$

Now K^* is greater than k , and K' is less than k' ; therefore the equations

$$\left. \begin{aligned} K &= \frac{2\sqrt{k}}{1+k} \\ \sin(2\Phi - \phi) &= k \sin \phi \\ Fk\phi &= \frac{2}{1+k} FK\Phi \end{aligned} \right\} \dots\dots\dots (30.),$$

which serve to determine the value of $Fk\phi$ in terms of $FK\Phi$, make the integration of a function having a less modulus to depend on the integration of one having a greater modulus. And the equations

$$\left. \begin{aligned} k &= \frac{1-K'}{1+K} \\ \tan(\phi - \Phi) &= K' \tan \Phi \\ FK\Phi &= \frac{1}{1+K'} Fk\phi \end{aligned} \right\} \dots\dots\dots (31.),$$

which serve to determine the value of $FK\Phi$ in terms of $Fk\phi$, make the integration of a function having a greater modulus to depend upon that of a function having a less.

And by a series of equations such as these, the value of an elliptic function may be made to depend upon that of another, as near to unity or as near to zero as we like.

If k^2 be greater than $\frac{1}{2}$, it will manifestly be more convenient to use the ascending scale, and if less the descending scale.

Let $K, K_1, K_2, \dots, K_n$ be a series of moduli, and $\Phi, \Phi_1, \Phi_2, \dots, \Phi_n$ a series of amplitudes taken in an ascending scale according to the conditions of equation (30.), so that

$$K = \frac{2\sqrt{k}}{1+k}, \quad K_1 = \frac{2\sqrt{K}}{1+K}, \quad K_2 = \frac{2\sqrt{K_1}}{1+K_1}, \text{ \&c.}$$

$$\Phi = \frac{1}{2} \phi + \frac{1}{2} \sin^{-1} k \sin \phi, \quad \Phi_1 = \frac{1}{2} \Phi + \frac{1}{2} \sin^{-1} K \sin \Phi, \quad \Phi_2 = \frac{1}{2} \Phi_1 + \frac{1}{2} \sin^{-1} K_1 \sin \Phi_1, \text{ \&c.} = \text{\&c.}$$

$$\text{Then} \quad Fk\phi = \frac{2}{1+k} FK\Phi, \quad FK\Phi = \frac{2}{1+K} FK_1\Phi_1, \quad FK_1\Phi_1 = \frac{2}{1+K_1} FK_2\Phi_2, \text{ \&c.} = \text{\&c.};$$

$$\therefore Fk\phi = \frac{2^{n+1} FK_n\Phi_n}{\prod_{i=1}^n (1+K_{i-1})^\dagger} \dots\dots\dots (N').$$

If, similarly, $k, k_1, k_2, k_3, \dots$ be moduli, and $\phi, \phi_1, \phi_2, \phi_3, \dots$ amplitudes determined according to the conditions of the descending scale of equations (31.), so that

$$k = \frac{1-K'}{1+K}, \quad k_1 = \frac{1-k'}{1+k'}, \quad k_2 = \frac{1-k'_1}{1+k'_1}, \quad k_3 = \frac{1-k'_2}{1+k'_2}, \text{ \&c.} = \text{\&c.}$$

$$\phi = \Phi + \tan^{-1} K' \tan \Phi, \quad \phi_1 = \phi + \tan^{-1} k' \tan \phi, \quad \phi_2 = \phi_1 + \tan^{-1} k'_1 \tan \phi_1, \text{ \&c.} = \text{\&c.}$$

$$\therefore FK\Phi = \frac{1}{1+K'} Fk\phi, \quad Fk\phi = \frac{1}{1+k'} Fk_1\phi_1, \quad Fk_1\phi_1 = \frac{1}{1+k'_1} Fk_2\phi_2, \quad Fk_2\phi_2 = \frac{1}{1+k'_2} Fk_3\phi_3, \text{ \&c.} = \text{\&c.}$$

$$\therefore \sin^2 2\Phi = \sin^2 \phi \{1 + k^2 + 2k \cos \phi \Delta k\phi - 2k^2 \sin^2 \phi\}$$

$$\sin 2\Phi = \sin \phi \{ \Delta k\phi + k \cos \phi \} \dots\dots\dots (\xi);$$

$$\therefore \sin(2\Phi - \phi) = k \sin \phi \cos(2\Phi - \phi) = \Delta k\phi$$

$$\sin \{ \Phi + (\Phi - \phi) \} + \sin \{ \Phi - (\Phi - \phi) \} = k \sin \phi + \sin \phi$$

$$\sin \{ \Phi + (\Phi - \phi) \} - \sin \{ \Phi - (\Phi - \phi) \} = k \sin \phi - \sin \phi$$

$$2 \sin \Phi \cos(\Phi - \phi) = (1+k) \sin \phi;$$

$$2 \cos \Phi \sin(\Phi - \phi) = -(1-k) \sin \phi; \therefore \tan(\Phi - \phi) = \frac{1-k}{1+k} \tan \Phi.$$

$$* \quad 1 > \sqrt{k}; \therefore 1 + \frac{1}{\sqrt{k}} > \sqrt{k} + \frac{1}{\sqrt{k}}; \therefore 1 + \frac{2}{\sqrt{k}} + \frac{1}{k} > k + 2 + \frac{1}{k}; \therefore \frac{2}{\sqrt{k}} > 1+k; \therefore \frac{2\sqrt{k}}{1+k} > k; \therefore K > k.$$

† K_{n-1} is here supposed to represent k .

Definite
Integrals.Definite
Integrals.

$$\therefore FK\Phi = \frac{Fk_n\phi_n}{\prod_n (1+k'_{n-1})^*} \dots\dots\dots (O').$$

or since

$$\frac{1}{1+k'_{n-1}} = \frac{1+k_n}{2};$$

$$\therefore FK\Phi = \frac{Fk_n\phi_n \cdot \prod_n (1+k_n)}{2^{n+1}} \dots\dots\dots (P'),$$

Suppose that n is taken so great that in the first case K_n may equal unity, and in the other case k_n may equal zero;

$$\therefore FK_n\Phi_n = \int \frac{d\Phi_n}{\cos \Phi_n} = \log. \tan \left(\frac{\pi}{4} + \frac{1}{2} \Phi_n \right),$$

$$Fk_n\phi_n = \int d\phi_n = \phi_n,$$

$$\therefore Fk\phi = \frac{2^{n+1} \log. \tan \left(\frac{\pi}{4} + \frac{1}{2} \Phi_n \right)}{\prod_n (1+K_{n-1})} \dots\dots\dots (32.).$$

$$FK\Phi = \frac{\phi_n}{\prod_n (1+k'_{n-1})} \dots\dots\dots (33.).$$

These two equations are sufficient to determine the numerical value of any elliptic function of the first order.

12. Now the values of all elliptic functions of the second and third orders may be determined in terms of those of elliptic functions of the first order.

By equation (13.) we have†

$$d\Phi \Delta K\Phi = \frac{d\phi}{\Delta k\phi} \frac{\{k \cos \phi + \Delta k\phi\}^2}{2(1+k)},$$

$$\text{or} \quad 2(1+k) EK\Phi = \int \frac{d\phi}{\Delta k\phi} \{k \cos \phi + \Delta k\phi\}^2 = \int \frac{d\phi}{\Delta k\phi} \{2(\Delta k\phi)^2 + 2k \cos \phi \Delta k\phi - k'^2\};$$

$$\therefore (1+k) EK\Phi = Ek\phi + k \sin \phi - \frac{1}{2} k'^2 Fk\phi,$$

$$\text{or} \quad EK\Phi = \frac{Ek\phi}{1+k} - \frac{1}{2} (1-k) Fk\phi + \frac{k \sin \phi}{1+k} \dots\dots\dots (34.).$$

Thus the value of $EK\Phi$ is made to depend upon that of $Ek\phi$, and that of $Fk\phi$; K, Φ , depending upon k, ϕ , by the same relation which connects the amplitudes and moduli of functions of the first order.

By a *scale* of such amplitudes and moduli, we may, therefore, determine the value of $EK\Phi$ in terms of $Ek_n\phi_n$, where k_n approximates as nearly as we like to zero, and $Ek_n\phi_n$ to ϕ_n ; or in terms of $EK_n\Phi_n$, where K_n approximates as nearly as we like to unity, and $EK_n\Phi_n$ to $-\cos \Phi_n$. This process of reduction will be greatly facilitated if we assume

$$GK\Phi = EK\Phi - FK\Phi;$$

for subtracting from equation (34.) the equation

$$FK\Phi = \frac{1+k}{2} Fk\phi,$$

* k'_{n-1} is here supposed to represent K' .

† Differentiating equation (ε), see note, page 513,

$$2 \sin 2\Phi \frac{d\Phi}{d\phi} = \sin \phi \frac{\{k \cos \phi + \Delta k\phi\}^2}{\Delta k\phi};$$

$\therefore$ dividing by (ξ)

$$2 \frac{d\Phi}{d\phi} = \frac{k \cos \phi + \Delta k\phi}{\Delta k\phi}.$$

Also by (ε)

$$K^2 \sin^2 \Phi = \frac{K^2 (1 - \cos 2\Phi)}{2} = \frac{2k}{(1+k)^2} \{1 + k \sin^2 \phi - \cos \phi \Delta k\phi\};$$

$$\therefore \Delta K\Phi = \frac{\Delta k\phi + k \cos \phi}{1+k};$$

$$\therefore 2 \Delta K\Phi \frac{d\Phi}{d\phi} = \frac{\{k \cos \phi + \Delta k\phi\}}{(1+k) \Delta k\phi}.$$

Definite
Integrals.

we have

$$GK\Phi = \frac{1}{1+k} \{Gk\phi - kFk\phi + k \sin \phi\}.$$

Similarly,

$$Gk\phi = \frac{1}{1+k_1} \{Gk_1\phi_1 - k_1Fk_1\phi_1 + k_1 \sin \phi_1\}$$

&c. = &c.

$$Gk_{n-1}\phi_{n-1} = \frac{1}{1+k_n} \{Gk_n\phi_n - k_nFk_n\phi_n + k_n \sin \phi_n\};$$

∴ by elimination

$$GK\Phi = \sum_n^0 \left\{ \frac{k_n \{ \sin \phi_n - Fk_n \phi_n \}}{\mathbf{P}_n(1+k_n)} \right\} + \frac{Gk_n \phi_n}{\mathbf{P}_n(1+k_n)},$$

Now, by equation (P)

$$\frac{Fk_n \phi_n}{\mathbf{P}_n(1+k_n)} = \frac{2^{n+1} FK\Phi}{\mathbf{P}_n(1+k_n)^2};$$

also

$$\frac{k_{n-1}^2}{k_n} = \frac{2^2}{(1+k_n)^2};$$

$$\therefore \frac{2^{n+1} k_{n+1}}{\mathbf{P}_n(1+k_n)^2} = \frac{k_n}{2^{n+1}} \mathbf{P}_n \frac{k_{n-1}^2}{k_n} = \frac{K^2}{2^{n+1}} \mathbf{P}_n k_{n-1};$$

$$\therefore GK\Phi = \sum_n^0 \left\{ \frac{K \sin \phi_n \mathbf{P}_n k_{n-1} - K^2 \cdot FK\Phi \cdot \mathbf{P}_n k_{n-1}}{2^{n+1}} \right\} + \frac{KGk_n \phi_n}{2^{n+1} k} \mathbf{P}_n k_{n-1} \dots \dots \dots (35.).$$

LEMMA III. Let $Q = \frac{\tan \phi}{\Delta k \phi}$, and let ι be an indeterminate quantity;

$$\therefore \frac{dQ}{1+\iota Q^2} = \frac{d\phi}{\Delta k \phi} \cdot \frac{1 - k^2 \sin^4 \phi}{(1 - k^2 \sin^2 \phi) \cos^2 \phi + \iota \sin^2 \phi}.$$

Let the denominator of this last fraction equal the product of the factors

$$(1 + n \sin^2 \phi) \left(1 + \frac{k^2}{n} \sin^2 \phi \right),$$

then will

$$\iota = (1+n) \left(1 + \frac{k^2}{n} \right);$$

$$\therefore \frac{1}{\sqrt{\iota}} \tan^{-1} \sqrt{\iota} \left(\frac{\tan \phi}{\Delta k \phi} \right) = \int \frac{d\phi}{\Delta k \phi} \frac{1 - k^2 \sin^4 \phi}{(1 + n \sin^2 \phi) \left(1 + \frac{k^2}{n} \sin^2 \phi \right)} \dots \dots \dots (Q').$$

The second member of this equation may be put under the form

$$\int \frac{d\phi}{\Delta k \phi} \left\{ \frac{1}{1 + n \sin^2 \phi} + \frac{1}{1 + \frac{k^2}{n} \sin^2 \phi} - 1 \right\};$$

$$\therefore \Pi n k \phi + \Pi \frac{k^2}{n} k \phi = Fk\phi + \frac{1}{\sqrt{\iota}} \tan^{-1} \sqrt{\iota} \frac{\tan \phi}{\Delta k \phi} \dots \dots \dots (R').$$

LEMMA IV. If we assume

$$\sin \phi = \frac{(1+K) \sin \Psi}{1 + K \sin^2 \Psi},$$

then will

$$Fk\phi = (1+K) FK\Psi,$$

where

$$\frac{2\sqrt{K}}{1+K} = k,$$

for

$$d\phi = \frac{(1+K) d\Psi}{\sqrt{1-K^2 \sin^2 \Psi}} \cdot \frac{1 - K \sin^2 \Psi}{1 + K \sin^2 \Psi},$$

but

$$\frac{1 - K \sin^2 \Psi}{1 + K \sin^2 \Psi} = \sqrt{1 - k^2 \sin^2 \phi};$$

$$\therefore \frac{d\phi}{\sqrt{1 - k^2 \sin^2 \phi}} = (1+K) \frac{d\Psi}{\sqrt{1 - K^2 \sin^2 \Psi}},$$

∴ &c.

Definite
Integrals.

Definite
Integrals.

13. On the reduction of elliptic functions of the third order.

 Definite
Integrals.

Assume

$$\sin \phi = \frac{(1+K) \sin \Psi}{1+K \sin^2 \Psi};$$

$$\therefore \Pi n k \phi = \int \frac{1}{1+n \sin^2 \phi} \frac{d\phi}{\Delta k \phi} = (1+K) \int \frac{d\Psi}{\Delta K \Psi} \frac{\{1+K \sin^2 \Psi\}^2}{(1+K \sin^2 \Psi)^2 + n(1+K)^2 \sin^2 \Psi}.$$

Let the denominator of this fraction be assumed equal to the product

$$(1+M \sin^2 \Psi)(1+N \sin^2 \Psi)$$

Equating the coefficients

$$\begin{cases} M+N=2K+n(1+K)^2 \\ MN=K^2 \end{cases}$$

where M and N may be found. Of these let N be the less, then is N less than K.

$$\begin{aligned} \text{Now } \{1+K \sin^2 \Psi\}^2 &= (1+K \sin^2 \Psi) + K(1+K \sin^2 \Psi) \sin^2 \Psi \\ &\quad + \kappa(1-K^2 \sin^4 \Psi) - \kappa(1-K \sin^2 \Psi)(1+K \sin^2 \Psi), \end{aligned}$$

 where κ may be any whatever;

$$\therefore \{1+K \sin^2 \Psi\}^2 = \kappa(1-K^2 \sin^4 \Psi) + (1+K \sin^2 \Psi) \{(1-\kappa) + (1+\kappa)K \sin^2 \Psi\}$$

$$\therefore \Pi n k \phi = \kappa(1+K) \int \frac{d\Psi (1-K^2 \sin^4 \Psi)}{\Delta K \Psi (1+M \sin^2 \Psi)(1+N \sin^2 \Psi)} + (1+K) \int \frac{d\Psi \{1+K \sin^2 \Psi\} \{(1-\kappa) + (1+\kappa)K \sin^2 \Psi\}}{\Delta K \Psi \{1+M \sin^2 \Psi\} \{1+N \sin^2 \Psi\}}.$$

Assume

$$(1+\kappa)K = M(1-\kappa).$$

The second term of the above equation becomes then

$$(1+K)(1-\kappa) \int \frac{d\Psi}{\Delta K \Psi} \frac{1+K \sin^2 \Psi}{1+N \sin^2 \Psi}$$

$$= (1+K)(1-\kappa) \frac{K}{N} \int \frac{d\Psi}{\Delta K \Psi} \frac{\left(\frac{N}{K}-1\right) + (1+N \sin^2 \Psi)}{1+N \sin^2 \Psi}$$

$$= (1-\kappa) \frac{(1+K)(N-K)}{N} \Pi N K \Psi + (1-\kappa) \frac{(1+K)K}{N} F K \Psi$$

$$= -2\kappa(1+K) \Pi N K \Psi + (1+\kappa)(1+K) F K \Psi.$$

Also by Lemma III.

$$\int \frac{d\Psi}{\Delta K \Psi} \frac{1-K^2 \sin^4 \Psi}{(1+N \sin^2 \Psi)\left(1+\frac{K^2}{N} \sin^2 \Psi\right)} = \frac{1}{\sqrt{\epsilon}} \tan^{-1} \frac{\sqrt{\epsilon} \tan \Psi}{\Delta K \Psi},$$

where

$$\epsilon = (1+N)\left(1+\frac{K^2}{N}\right) = (1+N)(1+M) = 1+(M+N)+MN = (1+K)^2(1+n);$$

 $\therefore$ on the whole,

$$\Pi n k \phi = \frac{\kappa}{\sqrt{1+n}} \tan^{-1} \frac{\sqrt{\epsilon} \tan \Psi}{\Delta K \Psi} - 2\kappa(1+K) \Pi N K \Psi + (1+\kappa)(1+K) F K \Psi \dots (36.).$$

Also

$$(1+\kappa)K = (1-\kappa)M;$$

$$\therefore \kappa = \frac{M-K}{M+K} = \frac{M-\sqrt{MN}}{M+\sqrt{MN}} = \frac{M+N-2\sqrt{MN}}{M-N},$$

and

$$M-N = (1+K)\{4K+n(1+K)^2\}\sqrt{n};$$

$$\therefore \kappa = \frac{\sqrt{n}}{\left\{\frac{4K}{(1+K)^2} + n\right\}^{\frac{1}{2}}} \quad \kappa = \left\{\frac{n}{n+k^2}\right\}^{\frac{1}{2}}.$$

Thus, then, the value of a function of the third order may be found in terms of a function of the same order having a less modulus K, and a less parameter N.

14. On the theory of complete functions.

 If in equations (28.) we assume $\Phi = \frac{\pi}{2}$ and $\phi = \pi$, the second of these equations will be satisfied. Also from the third,

$$F k \pi = 2 F k \frac{\pi}{2} = \frac{2}{1+k} F K \frac{\pi}{2};$$

$$\therefore F k \frac{\pi}{2} = \frac{1}{1+k} F K \frac{\pi}{2};$$

$$\therefore F K \frac{\pi}{2} = \frac{2}{1+K'} F k \frac{\pi}{2}.$$

Definite
Integrals.

Also similar substitutions in the subsequent equations of the scale will satisfy, in each, the relation of the amplitudes.

Definite
Integrals.

$$\therefore Fk \frac{\pi}{2} = \frac{FK_n \frac{\pi}{2}}{\prod_n (1 + K_{n-1})} \dots \dots \dots (S'),$$

$$FK \frac{\pi}{2} = \frac{2^{n+1} Fk_n \frac{\pi}{2}}{\prod_n (1 + k'_{n-1})} \dots \dots \dots (T').$$

In equation (35.) let Φ be assumed $= \frac{\pi}{2}$, and $\phi = \pi$;

$$\therefore GK \frac{\pi}{2} = -\sum_n \left(\frac{K^2}{2^{n+1}} \right) FK \frac{\pi}{2} \prod_n k_{n-1};$$

since when $k_n = 0$, $Gk\phi_n = 0$;

$$\therefore EK \frac{\pi}{2} = FK \frac{\pi}{2} \left\{ 1 - \sum_n \frac{K^2}{2^{n+1}} \prod_n k_{n-1} \right\} \dots \dots \dots (U').$$

15. To determine the values of $Fk \frac{\pi}{2}$ and $Ek \frac{\pi}{2}$ in converging series when k is small.

Let

$$k = \frac{2\sqrt{K}}{1+K}$$

$$\therefore Fk\phi = F \frac{2\sqrt{K}}{1+K} \phi = \int \left\{ 1 - \frac{4K}{(1+K)^2} \sin^2 \phi \right\}^{-\frac{1}{2}} d\phi = (1+K) \int \{ 1 + 2K \cos 2\phi + K^2 \}^{-\frac{1}{2}} d\phi.$$

Let

$$\begin{aligned} \varepsilon^{2\phi} \sqrt{-1} &= x; \therefore 2 \cos 2\phi = x + x^{-1}; \\ \therefore Fk\phi &= (1+K) \int (1+Kx)^{-\frac{1}{2}} (1+Kx^{-1})^{-\frac{1}{2}} d\phi \\ &= (1+K) \int \left\{ 1 + \left(\frac{1}{2} \right)^2 K^2 + \left(\frac{1.3}{2.4} \right)^2 K^4 + \left(\frac{1.3.5}{2.4.6} \right)^2 K^6 + \dots \right. \\ &\quad \left. + A(x+x^{-1}) + B(x^3+x^{-3}) + \dots \right\} d\phi, \end{aligned}$$

where A, B, &c. are certain functions of K;

$$\therefore Fk\phi = (1+K) \left\{ 1 + \left(\frac{1}{2} \right)^2 K^2 + \left(\frac{1.3}{2.4} \right)^2 K^4 + \left(\frac{1.3.5}{2.4.6} \right)^2 K^6 + \dots \right\} \phi + (1+K) \left\{ A \sin 2\phi + \frac{1}{2} B \sin 4\phi + \dots \right\}$$

$$\therefore Fk \frac{\pi}{2} = (1+K) \left\{ 1 + \left(\frac{1}{2} \right)^2 K^2 + \left(\frac{1.3}{2.4} \right)^2 K^4 + \left(\frac{1.3.5}{2.4.6} \right)^2 K^6 + \dots \right\} \frac{\pi}{2} \dots \dots \dots (37.).$$

Similarly $Ek\phi = (1+K)^{-1} \int \{ 1 + 2K \cos 2\phi + K^2 \}^{\frac{1}{2}} d\phi = (1+K)^{-1} \int (1+Kx)^{\frac{1}{2}} (1-Kx^{-1})^{\frac{1}{2}} d\phi$

$$= (1+K)^{-1} \int \left\{ 1 + \left(\frac{1}{2} \right)^2 K^2 + \left(\frac{1.3}{2.4} \right)^2 K^4 + \left(\frac{1.3.5}{2.4.6} \right)^2 K^6 + \dots + 2A \cos 2\phi + 2B \cos 4\phi + \dots \right\} d\phi;$$

$$\therefore Ek \frac{\pi}{2} = (1+K)^{-1} \left\{ 1 + \left(\frac{1}{2} \right)^2 K^2 + \left(\frac{1.3}{2.4} \right)^2 K^4 + \left(\frac{1.3.5}{2.4.6} \right)^2 K^6 + \dots \right\} \frac{\pi}{2} \dots \dots \dots (38.).$$

Now K is always less than k ; when, therefore, k is small, we may neglect the powers of K:

$$\therefore Fk \frac{\pi}{2} = \frac{\pi(1+K)}{2} \dots \dots \dots (V');$$

$$\therefore Ek \frac{\pi}{2} = \frac{\pi(1+K)^{-1}}{2} \dots \dots \dots (W');$$

$$\therefore Fk \frac{\pi}{2} \times Ek \frac{\pi}{2} = \frac{\pi^2}{4} \dots \dots \dots (X').$$

16. To determine the value of a complete function in a convergent series when its modulus very nearly equals unity.

$$Fk\phi = \int \sec \phi \{ 1 + k^2 \tan^2 \phi \}^{-\frac{1}{2}} d\phi.$$

Expanding and applying the formulæ of reduction

$$\int \sec \phi \tan^n \phi d\phi = \frac{1}{n} \sec \phi \tan^{n-1} \phi - \frac{n-1}{n} \int \sec \phi \tan^{n-2} \phi d\phi,$$

$$\begin{aligned} Fk\phi &= \int \sec \phi d\phi - \frac{1}{2} k^2 \left\{ \frac{1}{2} \sec \phi \tan \phi - \frac{1}{2} \int \sec \phi d\phi \right\} \\ &\quad + \frac{1.3}{2.4} k^4 \left\{ \frac{1}{4} \sec \phi \tan^3 \phi - \frac{3}{8} \sec \phi \tan \phi + \frac{3}{8} \int \sec \phi d\phi \right\} + \dots \end{aligned}$$

$$\underbrace{\text{Definite Integrals.}} = \left\{ 4 + \frac{1}{4} k'^2 + \frac{1.3}{2.4} \cdot \frac{3}{8} k'^4 + \dots \right\} \log. \{ \tan \phi + \sec \phi \} - \frac{1}{4} k'^2 \sec \phi \tan \phi \left\{ 1 - \frac{1.3}{2.4} k'^2 \tan^2 \phi + \frac{1.3}{2.4} \cdot \frac{3}{2} k'^2 + \dots \right\} \underbrace{\text{Definite Integrals.}}$$

Now let $2Fk\phi = Fk \frac{\pi}{2}$; $\therefore$ by equation (1.) $\tan \phi = \frac{1}{\sqrt{k'}}$;

$$\therefore \frac{1}{2} Fk \frac{\pi}{2} = \left\{ 1 + \frac{1}{4} k'^2 + \frac{1.3}{2.4} \cdot \frac{3}{8} k'^4 + \dots \right\} \log. \left\{ \frac{1}{\sqrt{k'}} + \sqrt{1 + \frac{1}{k'}} \right\} - \frac{1}{4} k' \sqrt{1 + k'} \left\{ 1 - \frac{1.3}{2.4} k' + \frac{1.3}{2.4} \cdot \frac{3}{2} k'^2 + \dots \right\}.$$

Now as k approaches unity, k' diminishes continually, therefore when k is very nearly equal to unity

$$\frac{1}{2} Fk \frac{\pi}{2} = \log. \frac{2}{\sqrt{k'}} \quad Fk \frac{\pi}{2} = \log. \left(\frac{4}{k'} \right) \dots \dots \dots (U').$$

Again,

$$Ek\phi = \int \cos \phi \{ 1 + k'^2 \tan^2 \phi \} d\phi;$$

whence expanding and applying the formulæ of reduction

$$\int \cos \phi \tan^n \phi d\phi = \frac{1}{n-2} \sin \phi \tan^{n-2} \phi - \frac{n-1}{n-2} \int \cos \phi \tan^{n-2} \phi d\phi;$$

$$\therefore Ek\phi = \left\{ \frac{k'^2}{2} + \frac{1.1}{2.4} \cdot \frac{3}{2} k'^4 + \dots \right\} \log. \{ \tan \phi + \sec \phi \} + \sin \phi \left\{ 1 + \frac{1}{2} k'^2 - \frac{1.1}{2.4} \cdot \frac{1}{2} k'^4 \tan^2 \phi - \frac{1.1}{2.4} \cdot \frac{3}{2} k'^4 \dots \right\}.$$

Assuming as before in equation (1.) $\phi_2 = \frac{\pi}{2} \phi_1 = \phi_2 = \phi \quad \tan \phi = \frac{1}{\sqrt{k'}}$.

Also by equation (3.) $2Ek\phi - Ek \frac{\pi}{2} = (1 - k'^2) \sin^2 \phi$; $\therefore 2Ek\phi - Ek \frac{\pi}{2} = 1 - k'$;

$$\therefore Ek \frac{\pi}{2} + (1 - k') = 2 \left\{ \frac{1}{2} k'^2 + \frac{1.1}{2.4} \cdot \frac{3}{2} k'^4 + \dots \right\} \log. \left\{ \frac{1 + \sqrt{1 + k'}}{\sqrt{k'}} \right\} + \frac{2}{\sqrt{1 + k'}} \left\{ 1 - \frac{1}{2} k'^2 - \frac{1.1}{2.4} \cdot \frac{1}{2} k'^3 - \dots \right\}.$$

Let now k very nearly equal unity, or k' very nearly equal zero;

$$\therefore Ek \frac{\pi}{2} + (1 - k') = \frac{1}{2} k'^2 \log. \frac{4}{k'} + 2 \left\{ 1 - \frac{1}{2} k' - \frac{1}{8} k'^2 + \dots \right\};$$

$$\therefore Ek \frac{\pi}{2} = 1 + \frac{1}{2} k'^2 \left\{ \log. \frac{4}{k'} - \frac{1}{2} \right\} \dots \dots \dots (V').$$

17. The remarkable relation $E_1 k \cdot E_1 k' - G_1 k \cdot G_1 k' = \frac{\pi}{2}$ between functions of the first and second orders, whose functions are complements of one another, was discovered by Legendre. It may be demonstrated as follows:

$$\frac{k^2 \sin \phi \cos \phi}{\Delta k \phi} = \int \frac{k^2 \cos^2 \phi - k^2 \sin^2 \phi + k^4 \sin^4 \phi}{(\Delta k \phi)^3} d\phi = \int \frac{-k'^2 + (\Delta k \phi)^4}{(\Delta k \phi)^3} d\phi = -k'^2 \int \frac{d\phi}{(\Delta k \phi)^3} + Ek\phi.$$

$$\text{Also } \frac{dEk\phi}{dk} = - \int \frac{k \sin^2 \phi}{\Delta k \phi} d\phi = - \frac{1}{k} \frac{1 - (\Delta k \phi)^2}{\Delta k \phi} = + \frac{1}{k} (Ek\phi - Fk\phi) = + \frac{1}{k} Gk\phi; \text{ similarly } \frac{dEk'\phi}{dk'} = + \frac{1}{k'} Gk'\phi$$

$$\frac{dFk\phi}{dk} = \int \frac{k \sin^2 \phi}{(\Delta k \phi)^3} d\phi = \frac{1}{k} \int \frac{1 - (\Delta k \phi)^2}{(\Delta k \phi)^3} d\phi = \frac{1}{k} \int \frac{d\phi}{(\Delta k \phi)^3} - \frac{1}{k} Fk\phi;$$

$$\therefore \frac{dF_1 k}{dk} = \frac{1}{k k'^2} \{ E_1 k - k'^2 F_1 k \} \quad \frac{dG_1 k}{dk} = \frac{d(E_1 k - F_1 k)}{dk} = - \left(\frac{k}{k'^2} \right) E_1 k.$$

$$\text{Similarly } \frac{dG_1 k'}{dk'} = - \left(\frac{k}{k'} \right) \frac{dG_1 k'}{dk'} = + \left(\frac{k}{k'} \right) \left(\frac{k'}{k^2} \right) E_1 k' = \frac{1}{k} E_1 k'; \text{ also } \frac{dE_1 k'}{dk} = - \left(\frac{k}{k'} \right) \frac{dE_1 k'}{dk'} = - \left(\frac{k}{k'^2} \right) G_1 k'$$

Now let $E_1 k \cdot E_1 k' - G_1 k \cdot G_1 k' = H$; differentiating in respect to k , and substituting

$$\frac{dH}{dk} = \frac{1}{k} G_1 k E_1 k' - \frac{k}{k'^2} G_1 k' E_1 k - G_1 k' \frac{dG_1 k}{dk} - G_1 k \frac{dG_1 k'}{dk'} = G_1 k \left\{ \frac{1}{k} E_1 k' - \frac{dG_1 k'}{dk_1} \right\} - G_1 k' \left\{ \frac{k}{k'^2} E_1 k - \frac{dG_1 k}{dk} \right\} = 0;$$

H does not then contain k . Let then k be indefinitely small; $\therefore$ by equations (R') (S')

$$F_1 k = \frac{1}{2} \pi (1 + K), \quad E_1 k = \frac{1}{2} \pi (1 + K)^{-1} = \frac{1}{2} \pi (1 - K); \quad \therefore G_1 k = -\pi K.$$

Also $E_1 k' = 1$, and by equations (U') $F_1 k' = \log. \left(\frac{4}{k} \right)$; $\therefore G_1 k' = 1 - \log. \left(\frac{4}{k} \right)$;

$$\therefore H = \frac{1}{2} \pi (1 - K) + \pi K \left\{ 1 - \log. \left(\frac{4}{k} \right) \right\} = \frac{\pi}{2} - K\pi \left\{ \log. \left(\frac{4}{k} \right) - \frac{1}{2} \right\} = \frac{\pi}{2} - \frac{K\pi}{k^2} \{ Ek' - 1 \} \text{ by equation (V')};$$

$$\therefore E_1 k \cdot E_1 k' - G_1 k G_1 k' = \frac{\pi}{2}.$$

ON THE RELATIONS OF ELLIPTIC FUNCTIONS TO THE PARTS OF A SPHERICAL TRIANGLE AND TO THE LENGTHS OF CERTAIN ALGEBRAICAL CURVES.

Let $A B C$ be a spherical triangle, whose sides a, b, c are respectively equal to the amplitudes ϕ_1, ϕ_2, ϕ_3 of three functions $Fk\phi_1, Fk\phi_2, Fk\phi_3$, such that

$$Fk\phi_1 \pm Fk\phi_2 - Fk\phi_3 = 0.$$

Then by the principles of spherical trigonometry

$$\cos C = \frac{\cos \phi_3 - \cos \phi_1 \cos \phi_2}{\sin \phi_1 \sin \phi_2} = \mp * \Delta k \phi_3 \text{ by equation (1.)}$$

$$\cos B = \frac{\cos \phi_2 - \cos \phi_1 \cos \phi_3}{\sin \phi_1 \sin \phi_3} = \pm * \Delta k \phi_2,$$

$$\cos A = \frac{\cos \phi_1 - \cos \phi_2 \cos \phi_3}{\sin \phi_2 \sin \phi_3} = \pm * \Delta k \phi_1;$$

$$\therefore \sin A = k \sin \phi_1, \quad \sin B = k \sin \phi_2, \quad \sin C = k \sin \phi_3.$$

Thus then the constant ratio of the sines of the sides and angles of a spherical triangle, thus formed, is equal to the common modulus of the function of which the sides are the amplitudes.

If there be taken a triangle polar or supplemental to this, then will the cosines of the sides of that triangle be represented by

$$\Delta k \phi_1, \quad \Delta k \phi_2, \quad \Delta k \phi_3,$$

and their sines will have to the sines of the opposite angles the ratio $\frac{1}{k}$ instead of k .

From C let fall a perpendicular CD upon AB ; $\therefore$ by Napier's analogies,

$$\tan AD = \cos A \tan \phi_3,$$

$$\tan BD = \cos B \tan \phi_1;$$

$$\therefore \phi_3 = \tan^{-1} (\tan \phi_1 \Delta k \phi_2) \pm \tan^{-1} (\tan \phi_2 \Delta k \phi_1) \dots \dots (W).$$

ANY ELLIPTIC FUNCTION MAY BE REPRESENTED BY THE ARC OF AN ALGEBRAICAL CURVE.

LEMMA V. To represent any given integral $\int P d\phi$ by the arc of an algebraical curve.

Let CY be a perpendicular from the origin C upon the tangent to the point P of a curve whose coordinates CM, MP , are x and y . Let $CY = PMPT = \phi$, $AP = s$;

$$\therefore P = y \sin \phi + x \cos \phi;$$

and observing that

$$\frac{dy}{d\phi} = \frac{ds}{d\phi} \cos \phi, \quad \frac{dx}{d\phi} = -\frac{ds}{d\phi} \sin \phi,$$

$$\frac{dP}{d\phi} = y \cos \phi - x \sin \phi.$$

From these two equations we have

$$\left. \begin{aligned} x &= P \cos \phi - \frac{dP}{d\phi} \sin \phi \\ y &= P \sin \phi + \frac{dP}{d\phi} \cos \phi \end{aligned} \right\} \dots \dots (X');$$

$$\therefore \frac{dx}{d\phi} = -\left(P + \frac{d^2P}{d\phi^2}\right) \sin \phi; \text{ and } \therefore \frac{ds}{d\phi} = P + \frac{d^2P}{d\phi^2};$$

$$\therefore s = \int P d\phi + \frac{dP}{d\phi} + C \dots \dots (Y).$$

By which equation the integral $\int P d\phi$ is expressed in terms of the arc s of an algebraical curve, and of the algebraical function $\frac{dP}{d\phi}$.

18. To represent an elliptic function of the FIRST ORDER by an algebraical curve.

Assume

$$P = \frac{1}{(1 - k^2 \sin^2 \phi)^{\frac{1}{2}}}; \quad \therefore \frac{dP}{d\phi} = \frac{k^2 \sin \phi \cos \phi}{(1 - k^2 \sin^2 \phi)^{\frac{3}{2}}};$$

by equation (Y')

$$\therefore Fk\phi = s - \frac{k^2 \sin \phi \cos \phi}{(1 - k^2 \sin^2 \phi)^{\frac{1}{2}}}$$

* The negative sign of the cosine of either angle indicates the angle to be an obtuse angle.

Definite
Integrals.

assuming the arc s to commence from the point where $\phi=0$. Equations (X') give the following values of x and y by which this curve may be traced :

Definite
Integrals.

$$x = \frac{\cos \phi}{(1 - k^2 \sin^2 \phi)^{\frac{3}{2}}} \{k'^2 + k^2 \cos 2\phi\},$$

$$y = \frac{\sin \phi}{(1 - k^2 \sin^2 \phi)^{\frac{3}{2}}} \{1 + k^2 \cos 2\phi\}.$$

The curve is the locus of the intersections of perpendiculars to the extremities of the consecutive diameters of an ellipse, the ratio of whose eccentricity to its semiaxis major is k , and whose semiaxis minor is unity.

Let PQ be a perpendicular to the extremity of any diameter CP of such an ellipse, and let AQB be the locus of the intersections of PQ in the consecutive positions of CP.

Let $PCB = \phi$, $CP = r$;
therefore by the polar equation to an ellipse from the centre

$$r = \frac{1}{(1 - k^2 \sin^2 \phi)^{\frac{1}{2}}}.$$

Now

$$\text{arc BQ} = \text{PQ} + \int r d\phi.$$

Also

$$\text{PQ} = \frac{dr}{d\phi} = \frac{k^2 \sin \phi \cos \phi}{(1 - k^2 \sin^2 \phi)^{\frac{3}{2}}};$$

$$\therefore \text{arc BQ} = \frac{k^2 \sin \phi \cos \phi}{(1 - k^2 \sin^2 \phi)^{\frac{3}{2}}} + Fk\phi,$$

or

$$Fk\phi = \text{arc BQ} - \frac{k^2 \sin \phi \cos \phi}{(1 - k^2 \sin^2 \phi)^{\frac{3}{2}}}.$$

As k is diminished the arc AQB continually approximates to the elliptic arc APB, from which indeed for small values of k it does not sensibly differ.

In the particular case in which $k^2 = \frac{1}{2}$, we obtain by elimination between equations (X') for the general equation to the curve

$$y^2 = 2 - \frac{1}{2}x^2 - \frac{3}{2}x^4.$$

19. It will be observed that the curve we have used serves to express the function $Fk\phi$ by the difference between the length of its arc and a certain function of the angle ϕ . In this particular case the function may be expressed by the length of a curve alone. That curve is the lemniscata.

The polar equation to the lemniscata is

$$r^2 = a^2 \cos 2\theta;$$

$$\therefore \frac{dr}{d\theta} = -\frac{a \sin 2\theta}{\sqrt{\cos 2\theta}};$$

$$\therefore s = \int \left\{ \left(\frac{dr}{d\theta} \right)^2 + r^2 \right\}^{\frac{1}{2}} d\theta = a \int \left\{ \frac{\sin^2 2\theta}{\cos 2\theta} + \cos 2\theta \right\}^{\frac{1}{2}} d\theta = a \int \frac{d\theta}{\sqrt{\cos 2\theta}}.$$

Let

$$\cos 2\theta = \cos^2 \phi; \quad \therefore \frac{d\theta}{d\phi} = \frac{\cos \phi \sin \phi}{\sqrt{1 - \cos^4 \phi}};$$

$$\therefore s = a \int \frac{\frac{d\theta}{d\phi} d\phi}{\cos \phi} = a \int \frac{\sin \phi d\phi}{\sqrt{1 - \cos^4 \phi}}$$

$$s = a \int \frac{d\phi}{\sqrt{1 + \cos^2 \phi}} = \frac{a}{\sqrt{2}} \int \frac{d\phi}{\sqrt{1 - \frac{1}{2} \sin^2 \phi}};$$

$$\therefore s = \frac{a}{\sqrt{2}} F \frac{1}{\sqrt{2}} \phi \dots \dots (Y').$$

Since an elliptic function of the first order may be added to, or subtracted from, another, or multiplied any number of times, or divided into any number of equal parts, therefore the arc of a lemniscata may likewise be added or subtracted, or be multiplied as many times as we like, or divided into as many parts as we like.

Let AP_1, AP_2, AP_3 be three arcs of a lemniscata whose semiaxis is a , and at the points P_1, P_2, P_3 let the radii vectores be r_1, r_2, r_3 .

Also let

$$\phi_1 = \cos^{-1} \frac{r_1}{a}, \quad \phi_2 = \cos^{-1} \frac{r_2}{a}, \quad \phi_3 = \cos^{-1} \frac{r_3}{a};$$

and let the points P_1, P_2, P_3 be so taken that

Definite
Integrals.

 Definite
Integrals.

$$\cos \phi_3 = \cos \phi_1 \cos \phi_2 - \sin \phi_1 \sin \phi_2 \Delta \frac{1}{\sqrt{2}} \phi_3;$$

$$\therefore AP_3 = AP_1 + AP_2.$$

From this formula we may double the arc of a lemniscata, or halve it.

Suppose, for example, that it is required to halve the arc AP_3 . Let P_1 and P_2 coincide;

$$\therefore AP_1 = \frac{1}{2} AP_3 \quad \cos^2 \phi_1 = \frac{\cos \phi_3 + \Delta \frac{1}{\sqrt{2}} \phi_3}{1 + \Delta \frac{1}{\sqrt{2}} \phi_3},$$

from which equation ϕ_1 , and therefore the position of P_1 , is known in terms of ϕ_3 . If the arc to be bisected is the whole semi lemniscata, then $r_3 = 0$; $\therefore \phi_3 = \frac{\pi}{2}$;

$$\therefore \cos^2 \phi_1 = \frac{\frac{1}{\sqrt{2}}}{1 + \frac{1}{\sqrt{2}}};$$

$$\therefore \cos \phi_1 = \sqrt{\sqrt{2} - 1}, \quad r_1 = a\sqrt{\sqrt{2} - 1}.$$

19. To represent an elliptic function of the SECOND ORDER by the length of a given curve.

Assume

$$P = (1 - k^2 \sin^2 \phi)^{\frac{1}{2}};$$

$\therefore$ by equation (Y').

$$s = Ek\phi - \frac{k^2 \sin \phi \cos \phi}{(1 - k^2 \sin^2 \phi)^{\frac{1}{2}}} + C.$$

Also by equations (X') we have

$$x = \frac{\cos \phi}{P}, \quad y = \frac{k' \sin \phi}{P},$$

between which, eliminating ϕ ,

$$y^2 = k'^2 (1 - x^2).$$

The equation to an ellipse whose semiaxis major is unity, and the ratio of its eccentricity to its semiaxis major k . If we suppose s to be measured from the extremity of the axis major, the constant disappears, and we have

$$Ek\phi = s + \frac{k^2 \sin \phi \cos \phi}{(1 - k^2 \sin^2 \phi)^{\frac{1}{2}}}, \dots \dots \dots (Z').$$

Let P_1 be any point in an ellipse, whose semiaxis major is a , and the ratio of its semiaxis major to its eccentricity k , and let Q_1 be the intersection of the ordinate M_1P_1 , produced, with the circumscribing circle.

Let $Q_1CB = \phi_1$; $\therefore CM_1 = x = a \sin \phi_1$, $M_1P_1 = y = b \cos \phi_1$;

$\therefore$ calling E_1 the length of the arc BP_1 ,

$$\frac{dE_1}{d\phi_1} = (a^2 \cos^2 \phi_1 + b^2 \sin^2 \phi_1)^{\frac{1}{2}} = a(1 - k^2 \sin^2 \phi_1)^{\frac{1}{2}};$$

$$\therefore E_1 = a Ek\phi_1 \dots \dots \dots (A'');$$

the constant disappearing, since when $E_1 = 0$ $\phi_1 = 0$. If ϕ_2, ϕ_3 be similarly taken in respect to two other points P_2 and P_3 of the ellipse; then if there exist between ϕ_1, ϕ_2, ϕ_3 the relation

$$\cos \phi_3 = \cos \phi_1 \cos \phi_2 - \sin \phi_1 \sin \phi_2 \Delta k \phi_3$$

there will exist between the arcs BP_1, BP_2, BP_3 the relation

$$*BP_1 + BP_2 - BP_3 = ak^2 \sin \phi_1 \sin \phi_2 \sin \phi_3 \dots \dots \dots (B'');$$

$$\therefore BP_1 + P_2P_3 = ak^2 \sin \phi_1 \sin \phi_2 \sin \phi_3 \dots \dots \dots (C'');$$

or if ϕ_2 be $> \phi_3$,

$$BP_1 - P_2P_3 = ak^2 \sin \phi_1 \sin \phi_2 \sin \phi_3.$$

Let P_3 coincide with A ;

$$\therefore \phi_3 = \frac{\pi}{2}, \quad k' \tan \phi_1 \tan \phi_2 = 1, \quad BP_1 - P_2A = ak^2 \sin \phi_1 \sin \phi_2,$$

or eliminating ϕ_2

$$BP_1 - AP_2 = \frac{ak^2 \sin \phi_1 \cos \phi_1}{\Delta k \phi_1},$$

therefore the difference of the arcs BP_1 and AP_2 is equal to the perpendicular from C on a tangent to P_1 ; a

*

$$BP_1 + BP_2 - BP_3 = \frac{k^2 M_1Q_1 \times M_2Q_2 \times M_3Q_3}{a^2}.$$

Thus we can determine the arc of an ellipse which shall differ in length from the sum of two others by a given straight line, or conversely.

Definite
Integrals.

property which was discovered by Fagani, and bears his name. It may also be deduced from a comparison of equations (Z') and (A').

Definite
Integrals.

Suppose the points P_1 and P_2 to coincide;

$$\therefore BP_1 - AP_1 = ak^2 \sin^2 \phi_1,$$

and

$$\sin^2 \phi_1 = \frac{1}{1+k'};$$

$$\therefore BP_1 - AP_1 = a(1-k') = a-b.$$

If, therefore, the point P_1 be taken according to the condition $\tan \phi_1 = \frac{1}{\sqrt{k'}}$, then will the difference of the arcs

BP_1 and AP_1 equal that of the semiaxes of the ellipse. Let it be required to determine two arcs of the same quadrant of an ellipse which shall be equal to one another. Call ϕ_2, ϕ_3 the angles corresponding to the extremities of one of the arcs P_2, P_3 , and ϕ'_2, ϕ'_3 those corresponding to the extremities of the other P'_2, P'_3 . Also let there exist between the quantities $\phi_2, \phi_3, \phi'_2, \phi'_3$ the relation

$$\frac{\sin \phi_2 \cos \phi_3 \Delta \phi_3 + \sin \phi_3 \cos \phi_2 \Delta \phi_2}{1-k^2 \sin^2 \phi_2 \sin^2 \phi_3} = \frac{\sin \phi'_2 \cos \phi'_3 \Delta \phi'_3 + \sin \phi'_3 \cos \phi'_2 \Delta \phi'_2}{1-k^2 \sin^2 \phi'_2 \sin^2 \phi'_3} \dots \dots \dots (D''),$$

and let each of these equal $\sin \phi_1$; $\therefore$ by equation (8.) and equation (C'')

$$BP_1 + P_2 P_3 = ak^2 \sin \phi_1 \sin \phi_2 \sin \phi_3, \quad BP_1 + P'_2 P'_3 = ak^2 \sin \phi_1 \sin \phi'_2 \sin \phi'_3.$$

If, then,

$$\sin \phi_2 \sin \phi_3 - \sin \phi'_2 \sin \phi'_3 = 0. \dots \dots \dots (E'')$$

$$P_2 P_3 = P'_2 P'_3.$$

The relation (D'') becomes by means of (E'')

$$\sin \phi_2 \cos \phi_3 \Delta \phi_3 + \sin \phi_3 \cos \phi_2 \Delta \phi_2 = \sin \phi'_2 \cos \phi'_3 \Delta \phi'_3 + \sin \phi'_3 \cos \phi'_2 \Delta \phi'_2 \dots \dots \dots (F'').$$

There are two equations of condition, (E'') and (F''), between the four quantities $\phi_2, \phi_3, \phi'_2, \phi'_3$. Any two of these are, therefore, indeterminate: and hence it follows that *any* are being given we can determine another, and only one other, in the same quadrant which shall be of the same length.

20. To represent an elliptic function of the THIRD ORDER by the length of a given curve.

Assume

$$P = (1+n \sin^2 \phi)^{-1} (1-k^2 \sin^2 \phi)^{-\frac{1}{2}};$$

substitution in equations (X') will then give the following values for the coordinates of the curve:

$$x = \frac{\cos \phi}{(1+n \sin^2 \phi)(1-k^2 \sin^2 \phi)^{\frac{3}{2}}} \{1 + (3n-2k^2) \sin^2 \phi - 4k^2 n \sin^4 \phi\}$$

$$y = \frac{\sin \phi}{(1+n \sin^2 \phi)(1-k^2 \sin^2 \phi)^{\frac{3}{2}}} \{1 + k^2 - 2n + (3n-1)(1+k^2) \sin^2 \phi - 4k^2 n \sin^4 \phi\};$$

and by equation (Y') the function will be determined in terms of the length of the curve by the equation

$$\Pi n k \phi = s + \frac{2n \sin \phi \cos \phi}{(1+n \sin^2 \phi)^2 (1-k^2 \sin^2 \phi)^{\frac{3}{2}}} - \frac{k^2 \sin \phi \cos \phi}{(1+n \sin^2 \phi)(1-k^2 \sin^2 \phi)^{\frac{3}{2}}}.$$

21. Let k and k' be the semiaxes of an hyperbola; then will its equation be

$$y^2 = \frac{k'^2}{k^2} (x^2 - k^2).$$

Let

$$y = k'^2 \tan \phi;$$

$$\therefore x = k \{1 + k'^2 \tan^2 \phi\}^{\frac{1}{2}};$$

$\therefore$ taking Y to represent an arc of this hyperbola,

$$dY = \frac{k'^2 \sec^2 \phi d\phi}{\sqrt{1-k'^2 \sin^2 \phi}}.$$

Now

$$d\{\tan \phi \Delta k \phi\} = \Delta k \phi \sec^2 \phi d\phi - \frac{k'^2 \sin^2 \phi d\phi}{\Delta k \phi}$$

$$= \Delta k \phi d\phi + \frac{k'^2 \tan^2 \phi}{\Delta k \phi} d\phi$$

$$= \Delta k \phi d\phi + \frac{k'^2 \sec^2 \phi d\phi}{\Delta k \phi} - k'^2 \frac{d\phi}{\Delta k \phi};$$

$$\therefore \tan \phi \Delta k \phi = Ek\phi + Y - k'^2 Fk\phi$$

$$Y = \tan \phi \Delta k \phi - Ek\phi + k'^2 Fk\phi \dots \dots \dots (G'').$$

If L , a perpendicular from the centre C of the hyperbola, on the point whose coordinates are x, y , then will

$$L = \tan \phi \Delta k \phi;$$

$$\therefore Y = L - Ek\phi + k'^2 Fk\phi \dots \dots \dots (H'').$$

Let

$$Yk\phi - Lk\phi = Hk\phi$$

Definite Integrals. that

Definite Integrals.

$$Hk\phi_1 + Hk\phi_2 - Hk\phi_3 = Ek\phi_1 + Ek\phi_2 - Ek\phi_3;$$

$$\therefore Hk\phi_1 + Hk\phi_2 - Hk\phi_3 = k^2 \sin \phi_1 \sin \phi_2 \sin \phi_3 \dots (I'');$$

or the same relation obtains between the functions H as between the functions E ; or if a curve be supposed to be taken whose length shall always equal the difference between the length of an hyperbolic arc and the perpendicular let fall upon its tangent, then will the arcs of this curve have to one another the same relation as those of an ellipse. By equation (32.)

$$2(1+k)EK\Phi = 2Ek\phi - k^2 Fk\phi + 2k \sin \phi;$$

also by equation (G'')

$$Yk\phi = k^2 Fk\phi - Ek\phi + \tan \phi \Delta \phi;$$

$$\therefore Yk\phi = Ek\phi - 2(1+k)EK\Phi + \{2k \sin \phi + \tan \phi \Delta \phi\}.$$

Thus, then, the length of an hyperbolic arc may always be represented by a straight line, increased by the difference of two elliptic arcs, whose eccentricities are connected by the equation (K'), and their amplitudes by (L').

This is the theorem of Landen.

EULERIAN INTEGRALS.

SECTION VI.

The definite integrals

$$\int_0^1 \frac{x^{p-1} dx}{(1-x^q)^{\frac{n-q}{q}}} \text{ and } \int_0^1 \left\{ \log \frac{1}{x} \right\}^{\frac{p}{q}-1} dx$$

have received the name of the integrals of Euler, by whom they were first treated as functions of their exponents p and q , and shown under this form to have certain remarkable relations to one another, and an extensive application in various branches of analysis.

In respect to integrals embraced under the first form, and called those of the first class, the investigations of Euler did not extend beyond that case in which the exponents n, p, q , are whole numbers, and his comparison of different integrals was made on the supposition that n remained the same. In respect to integrals of the second class, he confined himself to the case in which p and q are whole numbers, and compared only those in which q remained the same.

As our object here is, however, to present the discussion under the form in which the more recent researches of Legendre, Poisson, and Jacobi have left it, we shall consider these integrals (after Legendre) as embraced under the following more general forms:

$$\int_0^1 (1-x)^{q-1} x^{p-1} dx \text{ represented by the symbol } [p, q]$$

$$\int_0^1 \left\{ \log \frac{1}{x} \right\}^{p-1} dx \text{ represented by the symbol } \Gamma p.$$

Both these classes of functions are considered as continuous. The latter are commonly known by the name of the functions *Gamma*, from the symbol which distinguishes them, and for a similar reason the first will in this paper be designated *Parenthetical Functions*.

It will be convenient to include both these classes of integrals under the same discussion, and to take first in order the functions *gamma*, on which the values of the *parenthetical* function may be made to depend.

Let

$$u = x \left\{ \log \frac{1}{x} \right\}^p;$$

$$\therefore \frac{du}{dx} = \left\{ \log \frac{1}{x} \right\}^p - p \left\{ \log \frac{1}{x} \right\}^{p-1};$$

and observing that between the limits 0 and 1, $u=0$, we obtain by integration

$$0 = \int_0^1 \left\{ \log \frac{1}{x} \right\}^p dx - p \int_0^1 \left\{ \log \frac{1}{x} \right\}^{p-1} dx;$$

$$\therefore \Gamma(p+1) = p \Gamma p \dots (1.).$$

Also this is true for all positive values of p , therefore if q be any positive integer,

$$\Gamma(p+q-1) = p(p+1)(p+2) \dots (p+q-2) \Gamma p \dots (2.).$$

Let

$$p=1; \therefore \Gamma p = \int_0^1 dx = 1;$$

$$\therefore \Gamma q = 1.2.3.4 \dots (q-1) \dots (3.).$$

To determine a relation between the class of parenthetical functions and the functions *gamma*.

Assume

$$u = x^p (1-x)^{q-1};$$

$$\therefore \frac{du}{dx} = (p+q-1)x^{p-1}(1-x)^{q-1} - (q-1)x^p(1-x)^{q-2}.$$

Integrating and observing that, between the limits 0 and 1, $u=0$,

Definite
Integrals.

$$\gamma = (p+q-1) \int_0^1 x^{p-1}(1-x)^{q-1} dx - (q-1) \int_0^1 x^{p-1}(1-x)^{q-1} dx;$$

Definite
Integrals.

$$\therefore [p, q] = \frac{(q-1)}{(p+q-1)} [p, q-1] \dots \dots \dots (4.).$$

And this is true for all positive values of q . Supposing it, therefore, an integer, and observing that

$$[p, 1] = \int_0^1 x^{p-1} dx = \frac{1}{p},$$

we have

$$[p, q] = \frac{(q-1)(q-2)\dots 1}{(p+q-1)(p+q-2)\dots (p+1)} \cdot \frac{1}{p} \dots \dots \dots (5.)$$

Now by equations (2.) and (3.) the product in the numerator of this fraction equals Γq , and that in the denominator $\frac{\Gamma(p+q)}{\Gamma q}$;

$$\therefore [p, q] = \frac{\Gamma p \Gamma q}{\Gamma(p+q)} \dots \dots \dots (6.).*$$

This equation has been proved only in the case in which q is an integer; containing, however, no longer the indefinite product $(1.2.3\dots q-1)$, it may be considered continuous. Now the value of the second member will not be altered if p and q be interchanged therefore generally.

$$p, q] = [q, p] \dots \dots \dots (7.).$$

The integral $[p, q]$ may be exactly determined when $p+q=1$; for in this case

$$[p, q] = [p, 1-p] = \int_0^1 x^{p-1}(1-x)^{-p} dx.$$

Assume $1-x = \frac{x}{u}$; $\therefore x = \frac{u}{1+u}$; and the values of u corresponding to $x=0$ and $x=1$ are 0 and ∞ ;

$$\therefore \text{substituting,} \quad [p, 1-p] = \int_0^\infty \frac{u^{p-1} du}{1+u}.$$

Now from the *general* value of the integral $\int_0^\infty \frac{u^{p-1} du}{1+u^m}$ it may be shown that $\int_0^\infty \frac{u^{p-1} du}{1+u} = \frac{\pi}{\sin p\pi}$. Also by

$$\text{equation (6.) } [p, 1-p] = \frac{\Gamma p \Gamma(1-p)}{\Gamma 1} = \Gamma p \Gamma(1-p);$$

$$\therefore \Gamma p \Gamma(1-p) = \frac{\pi}{\sin p\pi} \dots \dots \dots (8.).$$

$\Gamma(1-p)$ is called the complement of Γp

$$\text{For } p \text{ substitute } \left(\frac{1}{2} + p\right); \therefore \Gamma\left(\frac{1}{2} + p\right) \Gamma\left(\frac{1}{2} - p\right) = \frac{\pi}{\cos p\pi}.$$

Moreover, by equation (1.),

$$\begin{aligned} \Gamma\left\{1 + \left(\frac{1}{2} + p\right)\right\} &= \left(\frac{1}{2} + p\right) \Gamma\left(\frac{1}{2} + p\right) \\ \Gamma\left\{1 + \left(\frac{1}{2} - p\right)\right\} &= \left(\frac{1}{2} - p\right) \Gamma\left(\frac{1}{2} - p\right); \end{aligned}$$

$$\therefore \Gamma\left\{1 + \left(\frac{1}{2} + p\right)\right\} \Gamma\left\{1 + \left(\frac{1}{2} - p\right)\right\} = \left\{\left(\frac{1}{2}\right)^2 - p^2\right\} \Gamma\left(\frac{1}{2} + p\right) \Gamma\left(\frac{1}{2} - p\right).$$

$$\text{Similarly,} \quad \Gamma\left\{2 + \left(\frac{1}{2} + p\right)\right\} \Gamma\left\{2 + \left(\frac{1}{2} - p\right)\right\} = \left\{\left(\frac{3}{2}\right)^2 - p^2\right\} \Gamma\left(1 + \frac{1}{2} + p\right) \Gamma\left(1 + \frac{1}{2} - p\right);$$

&c. = &c.

$$\therefore \Gamma\left(m - \frac{1}{2} + p\right) \Gamma\left(m - \frac{1}{2} - p\right) = \left\{\left(\frac{1}{2}\right)^2 - p^2\right\} \left\{\left(\frac{3}{2}\right)^2 - p^2\right\} \dots \dots \left\{\left(m - \frac{3}{2}\right)^2 - p^2\right\} \frac{\pi}{\cos p\pi} \dots \dots (9.);$$

where m is any positive integer, and the number of factors in the product is $(m-1)$. From which equation it appears that, dividing the values of Γp into periods, of which the first contains those between $\Gamma 0$ and $\Gamma 1$, the second those between $\Gamma 1$ and $\Gamma 2$, &c., the m th those between $\Gamma m-1$ and Γm ; then those which are contained in either half of each of these periods may be determined in terms of those in the other half. If we make $p=0$, we shall obtain for the middle term of the m th period,

$$\Gamma\left(m - \frac{1}{2}\right) = 1.3.5.7\dots(2m-3) \frac{\sqrt{\pi}}{2^{m-1}}.$$

* For a direct proof of this equation, including the positive fractional values of p and q , see Note 2 at the end of this paper.

Definite Integrals. Let $m=1$

$$\therefore \Gamma \frac{1}{2} = \sqrt{\pi}.$$

Definite Integrals.

In the function $[p, q]$ suppose $p=q$; $\therefore [p, p] = \int_0^1 x^{p-1} (1-x)^{p-1} dx$. Assume $x = \frac{1}{2}(1+u)$;

$$\therefore [p, p] = 2^{1-2p} \int_{-1}^1 (1-u^2)^{p-1} du; \text{ or } [p, p] = 2^{1-2p} \int_0^1 (1-u^2)^{p-1} du;$$

or, substituting x for u^2 ,

$$[p, p] = 2^{1-2p} \int_0^1 (1-x)^{p-1} x^{-\frac{1}{2}} dx;$$

$$\therefore [p, p] = 2^{1-2p} \left[p, \frac{1}{2} \right], \dots \dots (10.).$$

But by equation (6.)

$$[p, p] = \frac{\Gamma p \Gamma p}{\Gamma 2p} \text{ and } \left[p, \frac{1}{2} \right] = \frac{\Gamma \frac{1}{2} \Gamma p}{\Gamma \left(\frac{1}{2} + p \right)};$$

$$\therefore \Gamma p \Gamma \left(\frac{1}{2} + p \right) = 2^{(1-2p)} \sqrt{\pi} \cdot \Gamma 2p \dots \dots (11.).$$

The equations numbered from (1.) to (11.) include the whole theory of the functions gamma, and the parenthetical functions $[p, q]$; all the formulæ given by Euler and Legendre may be deduced from them.

The relation of Euler's functions, $\int_0^1 \frac{x^{p-1} dx}{(1-x)^{\frac{p+q}{n}}}$ represented by $\left(\frac{p}{q} \right)$, to the functions $[p, q]$ is expressed by the following equation:

$$\left[\frac{p}{n}, \frac{q}{n} \right] = n \left(\frac{p}{q} \right) \dots \dots (12.);$$

for

$$\left[\frac{p}{n}, \frac{q}{n} \right] = \int_0^1 x^{\frac{p}{n}-1} (1-x)^{\frac{q}{n}-1} dx.$$

Assuming therefore $x=u^n$,

$$\left[\frac{p}{n}, \frac{q}{n} \right] = n \int_0^1 u^{p-1} (1-u^n)^{\frac{q}{n}-1} du = n \left(\frac{p}{q} \right); \therefore \&c.$$

Also by equation (6.)

$$\left[\frac{p}{n}, \frac{q}{n} \right] = \frac{\Gamma \frac{p}{n} \Gamma \frac{q}{n}}{\Gamma \frac{p+q}{n}};$$

$$\therefore \left(\frac{p}{q} \right) = \frac{1}{n} \frac{\Gamma \frac{p}{n} \Gamma \frac{q}{n}}{\Gamma \frac{p+q}{n}} \dots \dots (13.).$$

By equation (1.)

$$\Gamma \frac{p+q}{n} = \left(\frac{p+q}{n} - 1 \right) \Gamma \left(\frac{p+q}{n} - 1 \right);$$

$$\therefore \left(\frac{p}{q} \right) = \frac{\Gamma \frac{p}{n} \Gamma \frac{q}{n}}{(p+q-n) \Gamma \left(\frac{p+q}{n} - 1 \right)} \dots \dots (14.).$$

The first of these formulæ is to be used when $p+q$ is $< n$, and the second when it is $> n$.

From the preceding formulæ may be deduced a great variety of others, applicable to particular cases of definite integration.

By equation (6.)

$$\left[p, \frac{1}{2} \right] = \frac{\Gamma p \Gamma \frac{1}{2}}{\Gamma \left(p + \frac{1}{2} \right)} \quad \left[\left(p + \frac{1}{2} \right), \frac{1}{2} \right] = \frac{\Gamma \left(p + \frac{1}{2} \right) \Gamma \frac{1}{2}}{\Gamma (p+1)}.$$

Also by equation (1.) $\Gamma (p+1) = p \Gamma p$;

$$\therefore \left[p, \frac{1}{2} \right] \left[\left(p + \frac{1}{2} \right), \frac{1}{2} \right] = \frac{\left(\Gamma \frac{1}{2} \right)^2}{p} = \frac{\pi}{p};$$

Definite
Integrals.

∴ by equation (12.)

$$\left(\frac{2p}{1}\right)\left(\frac{2p+1}{1}\right) = \frac{\pi}{4p}, \text{ taking } n=2;$$

or

$$\int_0^1 \frac{x^{2p-1}}{(1-x^2)^{\frac{1}{2}}} \cdot \int_0^1 \frac{x^{2p}}{(1-x^2)^{\frac{1}{2}}} = \frac{\pi}{4p}.$$

This theorem, which is commonly proved by a direct but more laborious method,* is a particular case of a more general theorem.

If n be any positive integer,

$$\left[p, \frac{1}{n}\right] = \frac{\Gamma p \Gamma \frac{1}{n}}{\Gamma\left(p + \frac{1}{n}\right)}, \left[\left(p + \frac{1}{n}\right), \frac{1}{n}\right] = \frac{\Gamma\left(p + \frac{1}{n}\right) \Gamma \frac{1}{n}}{\Gamma\left(p + \frac{2}{n}\right)} \&c. = \&c. \left[\left(p + \frac{n-1}{n}\right), \frac{1}{n}\right] = \frac{\Gamma\left(p + \frac{n-1}{n}\right) \Gamma \frac{1}{n}}{\Gamma(p+1)};$$

$$\begin{aligned} \therefore \left[p, \frac{1}{n}\right] \times \left[\left(p + \frac{1}{n}\right), \frac{1}{n}\right] \times \dots \times \left[\left(p + \frac{n-1}{n}\right), \frac{1}{n}\right] &= \frac{\left(\Gamma \frac{1}{n}\right)^n}{p} \\ \therefore \left(\frac{pn}{1}\right) \times \left(\frac{pn+1}{1}\right) \times \dots \times \left(\frac{np+n-1}{1}\right) &= \frac{\left(\Gamma \frac{1}{n}\right)^n}{n^n p}. \end{aligned} \quad \dots\dots\dots (15.);$$

Let $\log \frac{1}{x} = u^2; \therefore x = e^{-u^2}; \therefore dx = -2e^{-u^2} u du;$

also the limits 0 and 1 of x correspond to $u = \infty$ $u = 0$;

$$\begin{aligned} \therefore \int_0^1 \left\{ \log \frac{1}{x} \right\}^{p-1} dx &= -2 \int_{\infty}^0 u^{2p-1} e^{-u^2} du = 2 \int_0^{\infty} u^{2p-1} e^{-u^2} du; \\ \therefore \int_0^{\infty} u^{2p-1} e^{-u^2} du &= \frac{1}{2} \Gamma p. \end{aligned}$$

Let $p = \frac{1}{2}; \therefore \int_0^{\infty} e^{-u^2} du = \frac{1}{2} \Gamma \frac{1}{2} = \frac{1}{2} \sqrt{\pi} \dots\dots\dots (16.).$

Tables of the values of the functions gamma for all values of the exponent p having been calculated by Legendre, and the values of the parenthetical functions $[p, q]$ having been made to depend in every case upon those of the functions gamma, by the equations (6.), (13.), (14.), it will be sufficient here to refer the values of the latter to those of the former. The values of the parenthetical functions may, nevertheless, be approximated to, independently, and formulæ for that purpose are given by Legendre, (*Intégrales Eulériennes*, chap. iv.)

The following is the formula by which the tables of Legendre for the functions gamma were calculated.

$\Gamma(1+x)$ representing, when x is a positive integer, the product $1.2.3\dots x$; it is shown by Euler (*Cal. Diff.* p. 465), that

$$\log \Gamma(1+x) = x \log x + \frac{1}{2} \log (2\pi x) - x + \frac{A'}{1.2x} - \frac{B'}{3.4x^3} + \frac{C'}{5.6x^5} - \dots\dots$$

where $A' B' C'$ are the numbers known as the numbers of Bernoulli

Let $\log R = \frac{A'}{1.2x} - \frac{B'}{3.4x^3} + \frac{C'}{5.6x^5} \&c.;$

$$\therefore \log \Gamma(1+x) = \log x^x + \log (2\pi x)^{\frac{1}{2}} - \log e^x + \log R;$$

$$\therefore \Gamma(1+x) = \left(\frac{x}{e}\right)^x (2\pi x)^{\frac{1}{2}} R \dots\dots\dots (17.).$$

The first member of this equation has hitherto been taken to represent the product $1.2.3\dots x$, it has been taken, therefore, to represent only those values of the function gamma in which the exponent is an integer; the second member of this equation is, however, continuous. The whole equation is therefore continuous. It serves to determine the value of $\Gamma(1+x)$, and therefore, of Γx , which equals $\frac{\Gamma(1+x)}{x}$ for all values of x .

It is a remarkable property of the series which determines the value of $\log R$, that it is convergent only up to a certain term determined by the value of x ; and that after this term is attained, it becomes divergent. This feature of the calculation, to which particular attention must be paid, results from the irregular values of the Bernoullian numbers, which diminish to the third, and afterwards increase. A limit beyond which the number of the term of incipient divergence of necessity lies may be determined as follows. Let it be the $(n+1)$ th and let B_n and B_{n+1} be the n th and $(n+1)$ th numbers of Bernoulli.

$$\therefore \frac{B_n}{2n(2n-1)x^{2n-1}} < \frac{B_{n+1}}{(2n+2)(2n+1)x^{2n+1}}; \therefore \frac{B_{n+1}}{B^n} > \frac{(2n+2)(2n+1)}{(2n)(2n-1)} x^2.$$

* See Lacroix, *Traité des Différences*, p. 394 and 403.

Definite
Integrals.

Definite
Integrals.

But Euler has shown (*Cal. Diff.* p. 429.) that $\frac{(2n+2)(2n+1)}{4\pi^2}$ is a limit to which the first member of this inequality continually approaches, as n increases, but which it never exceeds;

 Definite
Integrals.

$$\therefore \frac{(2n+2)(2n+1)}{4\pi^2} > \frac{(2n+2)(2n+1)}{(2n)(2n-1)} x^2; \therefore 2n(2n-1) > 4\pi^2 x^2, \text{ and } n > \pi x.$$

SECTION VII.

THE SUM OF A SERIES OF PERIODICAL QUANTITIES MAY SOMETIMES BE DERIVED FROM A DEFINITE INTEGRAL.

Let α and p be any two real quantities, of which the latter is less than unity.

$$\frac{1}{1-p\varepsilon^{\alpha}\sqrt{-1}} = 1 + \sum_1^{\infty} p^n \varepsilon^{n\alpha} \sqrt{-1} \quad \frac{1}{1-p\varepsilon^{-\alpha}\sqrt{-1}} = 1 + \sum_1^{\infty} p^n \varepsilon^{-n\alpha} \sqrt{-1}.$$

Adding, and subtracting, and substituting $\cos \alpha$ and $\sin \alpha$ for these values in terms of $\varepsilon^{\sqrt{-1}}$ and $\varepsilon^{-\alpha}\sqrt{-1}$,

$$\frac{1-p\cos \alpha}{1-2p\cos \alpha+p^2} = 1 + \sum_1^{\infty} p^n \cos n\alpha \dots \dots (1).$$

$$\frac{p\sin \alpha}{1-2p\cos \alpha+p^2} = \sum_1^{\infty} p^n \sin n\alpha \dots \dots (2).$$

The first of these equations may be written thus,

$$\frac{1-p^2}{1-2p\cos \alpha+p^2} = 1 + 2\sum_1^{\infty} p^n \cos n\alpha \dots \dots (3).$$

Let k be any real or imaginary quantity, multiply both sides of this equation by $\varepsilon^{-k\alpha}$, and integrate in respect to α from $\alpha=0$ to $\alpha=x$;

$$\therefore \int_0^x \frac{(1-p^2)\varepsilon^{-k\alpha} d\alpha}{1-2p\cos \alpha+p^2} = \frac{1-\varepsilon^{-kx}}{k} + 2\varepsilon^{-kx} \sum_1^{\infty} \frac{np^n \sin nx}{k^2+n^2} - 2\varepsilon^{-kx} \sum_1^{\infty} \frac{kp^n \cos nx}{k^2+n^2} + 2 \sum_1^{\infty} \frac{kp^n}{k^2+n^2}.$$

Let $p=1-\rho$. The integer in the first member of this equation will then become

$$\int_0^x \frac{\rho(2+\rho)\varepsilon^{-k\alpha} d\alpha}{4(1-\rho)\sin^2 \frac{\alpha}{2} + \rho^2}.$$

Now, suppose ρ to be infinitely diminished, so that p may approach indefinitely to unity, all those elements of the integral which correspond to values of α , which are not also indefinitely small, will then manifestly be evanescent; the whole finite value of the integral will thus be made up of those elements for which α is indefinitely small, and it is immaterial within what limits we take it, provided we include these. Instead, then, of taking it between the limits 0 and x , let us take it from 0 to α^t , making at the same time α and ρ indefinitely small. The integral then becomes

$$\int_0^{\alpha^t} \frac{2\rho d\alpha}{\rho^2 + \alpha^2} = \pi.$$

Making, then, in the preceding equation, $p=1$, and supposing, $x>0$ and $<2\pi$,

$$\pi = \frac{1-\varepsilon^{-kx}}{k} + 2\varepsilon^{-kx} \sum_1^{\infty} \frac{n \sin nx}{k^2+n^2} - 2\varepsilon^{-kx} \sum_1^{\infty} \frac{k \cos nx}{k^2+n^2} + 2 \sum_1^{\infty} \frac{k}{k^2+n^2} \dots \dots (4.)$$

If the superior limit x be taken $=2\pi$, the quantity $\sin \frac{\alpha}{2}$ will become infinitely small immediately about the superior as well as the inferior limit, and there will be two periods immediately about these limits through which the integral will not be evanescent. The value of the integral for this last period may be determined like that of the first to equal $\pi\varepsilon^{-2k\pi}$, and taking $p=1$ $x=2\pi$, equation (4.) will become

$$\pi + \pi\varepsilon^{-2k\pi} = \frac{1-\varepsilon^{-2k\pi}}{k} - 2\varepsilon^{-2k\pi} \sum_1^{\infty} \frac{k}{k^2+n^2} + 2 \sum_1^{\infty} \frac{k}{k^2+n^2},$$

or

$$\frac{1}{k} + 2 \sum_1^{\infty} \frac{k}{k^2+n^2} = \left(\frac{\varepsilon^{k\pi} + \varepsilon^{-k\pi}}{\varepsilon^{k\pi} - \varepsilon^{-k\pi}} \right) \pi \dots \dots (5).$$

Adding this equation to equation (4.), we obtain

$$\varepsilon^{-kx} + \frac{2k\pi\varepsilon^{-k\pi}}{\varepsilon^{-k\pi} - \varepsilon^{k\pi}} = 2\varepsilon^{-kx} \sum_1^{\infty} \frac{nk \sin nx}{k^2+n^2} - 2\varepsilon^{-kx} \sum_1^{\infty} \frac{k^2 \cos nx}{k^2+n^2}.$$

Changing the sign of k ,

$$\varepsilon^{kx} + \frac{2k\pi\varepsilon^{k\pi}}{\varepsilon^{-k\pi} - \varepsilon^{k\pi}} = -2\varepsilon^{kx} \sum_1^{\infty} \frac{nk \sin nx}{k^2+n^2} - 2\varepsilon^{kx} \sum_1^{\infty} \frac{k^2 \cos nx}{k^2+n^2};$$

whence multiplying the first equation by ε^{kx} , and the second by ε^{-kx} , and subtracting and adding the two equations respectively,

Definite
Integrals.

$$\left. \begin{aligned} \frac{\pi}{2} \left\{ \frac{\varepsilon^{k(\pi-x)} - \varepsilon^{-k(\pi-x)}}{\varepsilon^{k\pi} - \varepsilon^{-k\pi}} \right\} &= \sum_0^\infty \frac{nk \sin nx}{k^2 + n^2} \\ \frac{\pi}{2k} \left\{ \frac{\varepsilon^{k(\pi-x)} + \varepsilon^{-k(\pi-x)}}{\varepsilon^{k\pi} - \varepsilon^{-k\pi}} \right\} &= \sum_0^\infty \frac{\cos nx}{k^2 + n^2} \end{aligned} \right\} \dots\dots\dots (6.).$$

Definite
Integrals.

These remarkable formulæ, first given by Poisson in the *Journal de l'Ecole Polytechnique** for 1823, may be considered as embracing all the results which analysts have hitherto obtained by different means with respect to the summation of series of the sines and cosines of multiple arcs, and of sines ascending inversely by the squares of the natural numbers.

It must be observed that they suppose the value of x to be included *between* the limits 0 and 2π , and that they do not necessarily exist at those limits, although the second in point of fact *does* by reason of the equation (5).

k may represent any quantity, real or imaginary: let it become $k\sqrt{-1}$;

$$\therefore \left. \begin{aligned} \frac{\pi}{2} \left\{ \frac{\sin k(\pi-x)}{\sin k\pi} \right\} &= \sum_0^\infty \frac{nk \sin nx}{n^2 - k^2} \\ \frac{\pi}{2k} \left\{ \frac{\cos k(\pi-x)}{\sin k\pi} \right\} &= \sum_0^\infty \frac{\cos nx}{n^2 - k^2} \end{aligned} \right\} \dots\dots\dots (7.).$$

THE ROOTS OF CERTAIN TRANSCENDENTAL EQUATIONS MAY BE EXPRESSED BY DEFINITE INTEGRALS.

Let $\phi\alpha$ be any function of α less than unity independently of the sign, and let x represent any real quantity;

$$\therefore -\log. (1 - \varepsilon^{x\sqrt{-1}}\phi\alpha) = \varepsilon^{x\sqrt{-1}}\phi\alpha + \frac{1}{2} \varepsilon^{2x\sqrt{-1}}\phi^2\alpha + \frac{1}{3} \varepsilon^{3x\sqrt{-1}}\phi^3\alpha + \dots$$

Now n and n' being any two different whole numbers, we have

$$\int_{-\pi}^{\pi} \varepsilon^{(n'-n)x\sqrt{-1}} dx = \int_{-\pi}^{\pi} \cos(n'-n)x dx + \sqrt{-1} \int_{-\pi}^{\pi} \sin(n'-n)x dx = 0.$$

But if n and n' represent the *same* whole number, this integral, instead of vanishing, evidently becomes 2π .

If, therefore, we assume n to be any positive whole number, and multiply the preceding equation first by $\varepsilon^{-nx\sqrt{-1}}$ and then by $\varepsilon^{nx\sqrt{-1}}$, and integrate, we shall obtain the equations

$$\int_{-\pi}^{\pi} \varepsilon^{-nx\sqrt{-1}} \log. (1 - \varepsilon^{x\sqrt{-1}}\phi\alpha) dx = \frac{2\pi}{n} \phi^n \alpha \quad \int_{-\pi}^{\pi} \varepsilon^{nx\sqrt{-1}} \log. (1 - \varepsilon^{x\sqrt{-1}}\phi\alpha) dx = 0.$$

Now let $F\alpha$ represent any other function of α ; then representing $\frac{dF\alpha}{d\alpha}$ by $F'\alpha$, multiplying the above equations by $\frac{1}{1.2.3\dots(n-1)} F'\alpha$; then differentiating them $(n-1)$ times in respect to α , and writing $fx\alpha$ for $F'\alpha \log. (1 - \varepsilon^{x\sqrt{-1}}\phi\alpha)$, we have

$$\begin{aligned} \frac{1}{1.2.3\dots(n-1)} \int_{-\pi}^{\pi} \varepsilon^{-nx\sqrt{-1}} \cdot \frac{d^{n-1}fx\alpha}{d\alpha^{n-1}} dx &= \frac{2\pi}{1.2.3\dots n} \frac{d^{n-1}\{F'\alpha \cdot (\phi\alpha)^n\}}{d\alpha^{n-1}} \\ \frac{1}{1.2.3\dots(n-1)} \int_{-\pi}^{\pi} \varepsilon^{nx\sqrt{-1}} \cdot \frac{d^{n-1}fx\alpha}{d\alpha^{n-1}} dx &= 0. \end{aligned}$$

Giving to n in these equations every value from 1 to ∞ , then adding them, observing that the terms under the sign of integration, the factors $\varepsilon^{-nx\sqrt{-1}}$ and $\varepsilon^{nx\sqrt{-1}}$ being omitted, will in the first represent the expansion of $f(x_1\alpha + \varepsilon^{x\sqrt{-1}})$, and in the second $f(x_1\alpha + \varepsilon^{-x\sqrt{-1}})$, and, finally, writing for these quantities their assumed values,

$$\begin{aligned} \frac{1}{2\pi} \int_{-\pi}^{\pi} \varepsilon^{-x\sqrt{-1}} F'(\alpha + \varepsilon^{-x\sqrt{-1}}) \cdot \log. \{1 - \varepsilon^{x\sqrt{-1}}\phi(\alpha + \varepsilon^{-x\sqrt{-1}})\} dx &= \frac{dF\alpha}{d\alpha} \cdot \phi\alpha \\ &+ \frac{1}{1.2} \frac{d\left\{\frac{dF\alpha}{d\alpha}(\phi\alpha)^2\right\}}{d\alpha} + \frac{1}{1.2.3} \frac{d^3\left\{\frac{dF\alpha}{d\alpha}(\phi\alpha)^3\right\}}{d\alpha^3} + \dots \end{aligned} \dots\dots\dots (8.),$$

$$\int_{-\pi}^{\pi} \varepsilon^{x\sqrt{-1}} \cdot F'(\alpha + \varepsilon^{x\sqrt{-1}}) \cdot \log. \{1 - \varepsilon^{x\sqrt{-1}}\phi(\alpha + \varepsilon^{x\sqrt{-1}})\} dx = 0 \dots\dots\dots (9.).$$

But by Lagrange's theorem, if y be determined by the relation $y = \alpha + \phi y$, the second number of the first of the above equations will be represented by $Fy - F\alpha$. Subject to this condition then

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \varepsilon^{-x\sqrt{-1}} \cdot F'(\alpha + \varepsilon^{-x\sqrt{-1}}) \cdot \log. \{1 - \varepsilon^{x\sqrt{-1}}\phi(\alpha + \varepsilon^{-x\sqrt{-1}})\} dx = Fy - F\alpha \dots\dots\dots (10.).$$

In the particular case in which $F\alpha = \alpha$, this last equation becomes

$$y = \alpha - \frac{1}{2\pi} \int_{-\pi}^{\pi} \varepsilon^{-x\sqrt{-1}} \cdot \log. \{1 - \varepsilon^{x\sqrt{-1}}\phi(\alpha + \varepsilon^{-x\sqrt{-1}})\} dx +$$

* Vol. xii. cahier 19, p. 418.

† This formula, representing under a finite form the root of the equation $y = \alpha + \phi y$, was first given by M. Perseval, (*Mém. Inst.*, tome i.)

Definite
Integrals.

Performing by parts the general integration, of which the definite integral is indicated in equation (10.), and observing that

Definite
Integrals.

$$F'(\alpha + \varepsilon^{-x} \sqrt{-1}) = \frac{dF(\alpha + \varepsilon^{-x} \sqrt{-1})}{d(\alpha + \varepsilon^{-x} \sqrt{-1})} = \frac{dF(\alpha + \varepsilon^{-x} \sqrt{-1})}{dx} \cdot \varepsilon^x \sqrt{-1} \cdot \sqrt{-1}$$

it becomes

$$\sqrt{-1} F(\alpha + \varepsilon^{-x} \sqrt{-1}) \log. \{1 - \varepsilon^x \sqrt{-1} \phi(\alpha + \varepsilon^{-x} \sqrt{-1})\} - \int \frac{\{\varepsilon^x \sqrt{-1} \cdot \phi(\alpha + \varepsilon^{-x} \sqrt{-1}) - \phi'(\alpha + \varepsilon^{-x} \sqrt{-1})\} F(\alpha + \varepsilon^{-x} \sqrt{-1})}{1 - \varepsilon^x \sqrt{-1} \phi(\alpha + \varepsilon^{-x} \sqrt{-1})} dx.$$

Now the quantity not included under the sign of integration being supposed developable in a converging series, according to the powers of $\varepsilon^x \sqrt{-1}$ and $\varepsilon^{-x} \sqrt{-1}$, it follows that it will assume the same* value at the limits $x = \pm \pi$, and that it will therefore disappear from the definite integral;

$$\therefore \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{\{\varepsilon^x \sqrt{-1} \cdot \phi(\alpha + \varepsilon^{-x} \sqrt{-1}) - \phi'(\alpha + \varepsilon^{-x} \sqrt{-1})\} F(\alpha + \varepsilon^{-x} \sqrt{-1})}{1 - \varepsilon^x \sqrt{-1} \phi(\alpha + \varepsilon^{-x} \sqrt{-1})} dx = Fy - F\alpha.$$

Now since $F(\alpha + \varepsilon^{-x} \sqrt{-1})$ may be expanded in a converging series, according to the powers of $\varepsilon^{-x} \sqrt{-1}$, and that every term of that series will vanish when integrated between the limits $x = \pm \pi$, except the first term, we have

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} F(\alpha + \varepsilon^{-x} \sqrt{-1}) dx = F\alpha.$$

Adding this to the preceding equation,

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{\{1 - \phi'(\alpha + \varepsilon^{-x} \sqrt{-1})\} F(\alpha + \varepsilon^{-x} \sqrt{-1})}{1 - \varepsilon^x \sqrt{-1} \phi(\alpha + \varepsilon^{-x} \sqrt{-1})} dx = Fy \dots \dots (11.).$$

Transforming equation (9.) in the same manner, it will become

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{\{1 + \varepsilon^{2x} \sqrt{-1} \cdot \phi'(\alpha + \varepsilon^x \sqrt{-1})\} F(\alpha + \varepsilon^x \sqrt{-1})}{1 - \varepsilon^x \sqrt{-1} \phi(\alpha + \varepsilon^x \sqrt{-1})} dx = F\alpha \dots \dots (12.).$$

Let P be a quantity independent of α and x , and less than unity, we may then assume $\phi y = P$, and $\therefore y = \alpha + P$.

By equation (11.)

$$\therefore \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{F(\alpha + \varepsilon^{-x} \sqrt{-1})}{1 - P \varepsilon^x \sqrt{-1}} dx = F(\alpha + P).$$

By equation (12.)

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{F(\alpha + \varepsilon^x \sqrt{-1})}{1 - P \varepsilon^x \sqrt{-1}} dx = F\alpha.$$

Now

$$\begin{aligned} \int_{-\pi}^{\pi} \frac{F(\alpha + \varepsilon^{-x} \sqrt{-1})}{1 - P \varepsilon^x \sqrt{-1}} dx &= \int_0^{\pi} \left\{ \frac{F(\alpha + \varepsilon^{-x} \sqrt{-1})}{1 - P \varepsilon^x \sqrt{-1}} + \frac{F(\alpha + \varepsilon^x \sqrt{-1})}{1 - P \varepsilon^{-x} \sqrt{-1}} \right\} dx, \\ \int_{-\pi}^{\pi} \frac{F(\alpha + \varepsilon^x \sqrt{-1})}{1 - P \varepsilon^x \sqrt{-1}} dx &= \int_0^{\pi} \left\{ \frac{F(\alpha + \varepsilon^x \sqrt{-1})}{1 - P \varepsilon^x \sqrt{-1}} + \frac{F(\alpha + \varepsilon^{-x} \sqrt{-1})}{1 - P \varepsilon^{-x} \sqrt{-1}} \right\} dx; \end{aligned}$$

therefore, adding and subtracting the preceding equations,

$$\begin{aligned} \frac{1}{\pi} \int_0^{\pi} \{F(\alpha + \varepsilon^{-x} \sqrt{-1}) \pm F(\alpha + \varepsilon^x \sqrt{-1})\} \left\{ \frac{1}{1 - P \varepsilon^x \sqrt{-1}} \pm \frac{1}{1 - P \varepsilon^{-x} \sqrt{-1}} \right\} dx &= F(\alpha + P) \pm F\alpha; \\ \therefore \frac{1}{\pi} \int_0^{\pi} \frac{\{F(\alpha + \varepsilon^{-x} \sqrt{-1}) + F(\alpha + \varepsilon^x \sqrt{-1})\} \{1 - P \cos x\}}{1 - 2P \cos x + P^2} dx &= F(\alpha + P) + F\alpha \\ \frac{P \sqrt{-1}}{\pi} \int_0^{\pi} \frac{\{F(\alpha + \varepsilon^{-x} \sqrt{-1}) - F(\alpha + \varepsilon^x \sqrt{-1})\} \sin x}{1 - 2P \cos x + P^2} dx &= F(\alpha + P) - F\alpha \end{aligned} \dots \dots (13.).$$

These results are of an exceedingly general form, for the function F may be any whatever; but it must not be forgotten, that although their form is finite, yet, being deduced from series which are infinite, they are not necessarily true if these series be divergent. The conditions on which the convergency of the series depend must not, therefore, be neglected; $\phi\alpha$ must be less than unity, and the value assigned to α must in no case be such as to give to the differential coefficients of $F\alpha$ an infinite value, or the second member of equation (10.) cannot be taken to represent the series in equation (8.).†

Making $P=0$ in the first of equations (13.),

$$\frac{1}{\pi} \int_0^{\pi} \{F(\alpha + \varepsilon^{-x} \sqrt{-1}) + F(\alpha + \varepsilon^x \sqrt{-1})\} dx = 2F\alpha.$$

Multiplying this equation by $\frac{1}{2}$, and subtracting it from the equation from which it has been deduced, there results the following:

* The reader will observe, that $\varepsilon^{\pm nx} \sqrt{-1}$ may be put under the form $\cos nx \pm \sqrt{-1} \sin nx$.

† For examples of the cases of exception the reader is referred to the paper in which Poisson has demonstrated these remarkable formulæ, *Journal de l'Ecole Polytechnique*, vol. xii. p. 483, &c.

Definite
Integrals.

$$\frac{1-P^2}{2\pi} \int_0^\pi \frac{F(\alpha + \varepsilon^{-x\sqrt{-1}}) + F(\alpha + \varepsilon^{x\sqrt{-1}})}{1-2P \cos x + P^2} dx = F(\alpha + P) \dots \dots (14.).$$

Definite
Integrals.

As an example of the application of equations (13.), let us assume $F\alpha = \alpha^A$, and let $\alpha = 1$. If we limit the values of A to those which are positive, this supposition will include none of the cases of exception. Also

$$F(1 + \varepsilon^{x\sqrt{-1}}) = 1 + (\varepsilon^{x\sqrt{-1}})^A = (1 + \cos x + \sqrt{-1} \sin x)^A = 2^A \cdot \cos^A \frac{x}{2} \cdot \left\{ \cos \frac{Ax}{2} + \sqrt{-1} \sin \frac{Ax}{2} \right\};$$

$$\therefore F(1 + \varepsilon^{-x\sqrt{-1}}) + F(1 + \varepsilon^{x\sqrt{-1}}) = 2^{A+1} \cdot \cos^A \frac{x}{2} \cdot \cos \frac{Ax}{2}$$

$$\{F(1 + \varepsilon^{-x\sqrt{-1}}) - F(1 + \varepsilon^{x\sqrt{-1}})\} \sqrt{-1} = 2^{A+1} \cdot \cos^A \frac{x}{2} \cdot \sin \frac{Ax}{2}.$$

By the substitution of which, equation (14.) becomes, dividing by 2^A and writing $2x$ for x ,

$$\left. \begin{aligned} \frac{2(1-P^2)}{\pi} \int_0^{\frac{\pi}{2}} \frac{\cos^A x \cdot \cos Ax}{1-2P \cos 2x + P^2} dx &= \left(\frac{1+P}{2} \right)^A \\ \text{and by the second of equations (13.)} \\ \frac{4P}{\pi} \int_0^{\frac{\pi}{2}} \frac{\cos^A x \sin Ax \sin 2x}{1-2P \cos 2x + P^2} dx &= \left(\frac{1+P}{2} \right)^A - \frac{1}{2^A} \end{aligned} \right\} \dots \dots (15.).$$

From these formulæ may be obtained an infinity of others by the method of differentiation under the sign of integration. Thus differentiating in respect to A , and then making $A=0$,

$$\begin{aligned} \frac{2(1-P^2)}{\pi} \int_0^{\frac{\pi}{2}} \frac{\log_e \cos x}{1-2P \cos 2x + P^2} dx &= \log_e \left(\frac{1+P}{2} \right), \\ \frac{4P}{\pi} \int_0^{\frac{\pi}{2}} \frac{x \sin 2x}{1-2P \cos 2x + P^2} dx &= \log_e (1+P). \end{aligned}$$

If we differentiate equations (15.) n times in respect to $P=0$ they will become

$$\begin{aligned} \frac{4}{\pi} \int_0^{\frac{\pi}{2}} \cos^A x \cdot \cos Ax \cdot \cos 2nx \, dx &= \frac{A(A-1)(A-2) \dots A-n+1}{1 \cdot 2 \cdot 3 \dots n} \cdot \frac{1}{2^A} \\ \frac{4}{\pi} \int_0^{\frac{\pi}{2}} \cos^A x \cdot \sin Ax \cdot \sin 2nx \, dx &= \frac{A(A-1)(A-2) \dots A-n+1}{1 \cdot 2 \cdot 3 \dots n} \cdot \frac{1}{2^A} \end{aligned}$$

Taking the sum and difference of these equations,

$$\begin{aligned} \frac{2}{\pi} \int_0^{\frac{\pi}{2}} \cos^A x \cdot \cos (A-2n)x \, dx &= \frac{A(A-1)(A-2) \dots (A-n+1)}{1 \cdot 2 \cdot 3 \dots n} \cdot \frac{1}{2^A} \\ \int_0^{\frac{\pi}{2}} \cos^A x \cdot \cos (A+2n)x \, dx &= 0. \end{aligned}$$

As another application of equations (13.) let us assume $F\alpha = \varepsilon^{A \cos x}$, A being a constant quantity, the factor $\varepsilon^{A \cos x}$ will be common to both sides of these equations, and the second of them and equation (14.) will give

$$\left. \begin{aligned} \frac{1-P^2}{\pi} \int_0^\pi \frac{\varepsilon^{A \cos x} \cos (A \sin x)}{1-2P \cos x + P^2} dx &= \varepsilon^{AP} \\ \frac{2P}{\pi} \int_0^\pi \frac{\varepsilon^{A \cos x} \sin (A \sin x) \sin x}{1-2P \cos x + P^2} dx &= \varepsilon^{AP} - 1 \end{aligned} \right\} \dots \dots (16.).$$

If we assume $P=0$, the first equation gives us

$$\frac{1}{\pi} \int_0^\pi \varepsilon^{A \cos x} \cdot \cos (A \sin x) \cdot dx = 1 \dots \dots (17.).$$

Equalling the coefficients of the same powers (n) of P in the expansions of the two members of equations (16.),

$$\left. \begin{aligned} \frac{2}{\pi} \int_0^\pi \varepsilon^{A \cos x} \cdot \cos (A \sin x) \cdot \cos nx \, dx &= \frac{a^n}{1 \cdot 2 \cdot 3 \dots n} \\ \frac{2}{\pi} \int_0^\pi \varepsilon^{A \sin x} \cdot \sin (A \sin x) \cdot \sin nx \, dx &= \frac{a^n}{1 \cdot 2 \cdot 3 \dots n} \end{aligned} \right\} \dots \dots (18.),$$

where n is any whole positive number.

If we assume the integrals to be taken in two distinct parts, the one extending between the limits 0 and $\frac{1}{2}\pi$, and the other from $\frac{1}{2}\pi$ to π , and in the first part substitute for x , $\frac{\pi}{2} - x$, and in the other part for x , $\frac{\pi}{2} + x$, then will the values of both parts of the integral remain unaltered, provided the limits of the integration of both be made 0 and $\frac{\pi}{2}$.

* Let Φx be any function of x ;

$$\therefore \int_0^{2a} \Phi x \, dx = \int_0^a \Phi x \, dx + \int_a^{2a} \Phi x \, dx.$$

In the first of these two integrals,

Definite Integrals.

If, moreover, we assume $n=2i$, or $2i-1$, according as it is even or odd, we shall obtain the four following equations:

Definite Integrals.

$$\begin{aligned} \frac{2}{\pi} \int_0^{\frac{\pi}{2}} (\varepsilon^{A \sin x} + \varepsilon^{-A \sin x}) \cos(A \cos x) \cos 2ix \, dx &= \frac{(-1)^i A^{2i}}{1.2.3 \dots (2i)} \\ \frac{2}{\pi} \int_0^{\frac{\pi}{2}} (\varepsilon^{A \sin x} - \varepsilon^{-A \sin x}) \cos(A \cos x) \sin(2i-1)x \, dx &= \frac{(-1)^{i-1} A^{2i-1}}{1.2.3 \dots (2i-1)} \\ \frac{2}{\pi} \int_0^{\frac{\pi}{2}} (\varepsilon^{-A \sin x} - \varepsilon^{A \sin x}) \sin(A \cos x) \sin 2ix \, dx &= \frac{(-1)^i A^{2i}}{1.2.3 \dots (2i)} \\ \frac{2}{\pi} \int_0^{\frac{\pi}{2}} (\varepsilon^{-A \sin x} + \varepsilon^{A \sin x}) \sin(A \cos x) \cos(2i-1)x \, dx &= \frac{(-1)^{i-1} A^{2i-1}}{1.2.3 \dots (2i-1)} \end{aligned}$$

As an example of the application of the general equation (11.), let us assume $\phi x = A\varepsilon^x$, A being a given constant, y will then be determined by the equation $y = \alpha + A\varepsilon^y$, and it will be expanded in a converging series by Lagrange's theorem, if $A\varepsilon^x$ be less than 1, independently of the sign. Supposing this, then, to be the case, assuming $Fx = \alpha$, and observing that $\phi'y = \phi y$ and $y = \alpha + \phi y$, so that $\alpha + \varepsilon^{-x\sqrt{-1}} = \alpha + \phi'(\alpha + \varepsilon^{-x\sqrt{-1}})$,

we have by equation (11.),

$$y = \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{(1 - \varepsilon^{-x\sqrt{-1}})(\alpha + \varepsilon^{-x\sqrt{-1}})}{1 - A\varepsilon^x \varepsilon^{\cos x} \varepsilon^{(x-\sin x)\sqrt{-1}}} dx.$$

Now since the value of $y - \alpha$ is, by Lagrange's theorem, a converging series, ascending by powers of A , it follows that the coefficient of α in the expansion of the second member of the above equation, is unity, or that

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{1 - \varepsilon^{-x\sqrt{-1}}}{1 - A\varepsilon^x \varepsilon^{\cos x} \varepsilon^{(x-\sin x)\sqrt{-1}}} dx = 1.$$

The value of y becomes, therefore,

$$y = \alpha + \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{(1 - \varepsilon^{-x\sqrt{-1}}) \varepsilon^{-x\sqrt{-1}}}{1 - A\varepsilon^x \varepsilon^{\cos x} \varepsilon^{(x-\sin x)\sqrt{-1}}} dx;$$

or observing that $1 - \varepsilon^{-x\sqrt{-1}} = 1 - \cos x + \sqrt{-1} \sin x = 2 \sin \frac{x}{2} \left\{ \sin \frac{x}{2} + \sqrt{-1} \cos \frac{x}{2} \right\}$

$$= 2\sqrt{-1} \sin \frac{x}{2} \left\{ \cos \frac{x}{2} - \sqrt{-1} \sin \frac{x}{2} \right\} = 2\sqrt{-1} \cdot \varepsilon^{-\frac{x}{2}\sqrt{-1}} \sin \frac{x}{2}$$

$$\frac{\sqrt{-1}}{\pi} \int_{-\pi}^{\pi} \frac{\varepsilon^{-\frac{x}{2}\sqrt{-1}} \sin \frac{x}{2}}{1 - A\varepsilon^x \varepsilon^{\cos x} \varepsilon^{(x-\sin x)\sqrt{-1}}} dx = 1$$

$$y = \alpha + \frac{\sqrt{-1}}{\pi} \int_{-\pi}^{\pi} \frac{\varepsilon^{-\frac{x}{2}\sqrt{-1}} \sin \frac{x}{2}}{1 - A\varepsilon^x \varepsilon^{\cos x} \varepsilon^{(x-\sin x)\sqrt{-1}}} dx$$

The imaginary quantities may be made to disappear from this equation by combining the elements of the integral, which correspond to positive and negative values of x , and integrating the whole, thus combined, from 0 to π . The following will be the result in the case in which $\alpha=0$,

$$\int y = \frac{2}{\pi} \int_0^{\pi} \left\{ \frac{\sin \frac{3}{2}x - A\varepsilon^{\cos x} \sin \left(\frac{5}{2}x - \sin x \right)}{1 - 2A\varepsilon^{\cos x} \cos(x - \sin x) + A^2 \varepsilon^{2 \cos x}} \right\} \sin \frac{x}{2} \, dx.$$

SECTION VIII.

The sum of a series of periodical quantities has in the preceding section been expressed by a definite integral, and in a particular case the integration has been performed, and the function itself which expresses this sum has been determined.

let x be assumed $= a - x_1$.

Now

$$\frac{d \int \Phi x \, dx}{dx_1} = - \frac{d \int \Phi x \, dx}{dx} \cdot \frac{dx_1}{dx} = - \frac{d \int \Phi x \, dx}{dx} = - \Phi x = - \Phi(a - x_1)$$

$$\therefore \int \Phi x \, dx = - \int \Phi(a - x_1) \, dx_1;$$

$$\therefore \int_0^a \Phi x \, dx = - \int_a^0 \Phi(a - x_1) \, dx_1 = \int_0^a \Phi(a - x_1) \, dx_1.$$

Similarly,

$$\int_a^{2a} \Phi x \, dx = \int_0^a \Phi(a + x_1) \, dx_1$$

Definite
Integrals.

The converse of this proposition is now to be discussed. IT IS PROPOSED TO EXPRESS THE VALUE OF A FUNCTION BETWEEN CERTAIN LIMITS OF THE VARIABLE ON WHICH IT DEPENDS, BY THE SUM OF A SERIES OF PERIODICAL INTEGRALS TAKEN BETWEEN THOSE LIMITS. Definite Integrals.

Let fx be an arbitrary function, whose values, between the limits fl and $f-l$, it is required to express by a series of periodical quantities.

In equation (3.) of the last section, if $\frac{\pi(x-x_1)}{l}$ be substituted for x , both sides multiplied by $\frac{fx_1}{l}$, and the equation integrated in respect to x_1 , between the limits l and $-l$, we shall obtain the following equation:

$$\int_{-l}^l \frac{(1-p^n) \cdot fx_1 \cdot dx_1}{2l \left\{ 1 - 2p \cos \frac{\pi(x-x_1)}{l} + p^2 \right\}} = \frac{1}{2l} \int_{-l}^l fx_1 dx_1 + \frac{1}{l} \sum_1^n p^n \left\{ \int_{-l}^l \cos \frac{n\pi(x-x_1)}{l} fx_1 dx_1 \right\}.$$

n being a whole positive number, and its values extending, under the symbol Σ , from 1 to infinity.

Now, suppose p to be indefinitely near to unity, the first member of this equation will then equal fx ; for, on this supposition, all the elements of the integral will be evanescent, except those for which $\cos \frac{\pi(x-x_1)}{l}$ approximates indefinitely to unity, or x_1 indefinitely to x . Let $x_1 = x + z$, and $1-p = \rho$. For those values of x_1 for which z is indefinitely small the integral becomes then

$$fx \cdot \int_{-(l-x)}^{(l-x)} \frac{\rho dz}{\rho^2 l^2 + \pi^2 z^2} \dots \dots (1.).$$

Moreover, since the integral in this expression is evanescent for all values of z , except such as are infinitely small, it is immaterial between what limits we take it, other than such as are infinitely small, and we may take it without altering its value between the limits $+\infty$ and $-\infty$, in which case it will become equal to unity, and the proposed integral will become fx .

Now this integral, thus taken, includes all the elements of the integral in the first member of the preceding equation, except those which are evanescent. Making $p = 1$;

$$\therefore fx = \frac{1}{2l} \int_{-l}^l fx_1 dx_1 + \frac{1}{l} \sum_1^n \left\{ \int_{-l}^l \cos \frac{n\pi(x-x_1)}{l} fx_1 \cdot dx_1 \right\} \dots \dots (2.).$$

This is the theorem of POISSON.*

It has been stated to be immaterial between what limits the integral (1.) is taken, provided they be not infinitely small, and the value of that integral is taken on the supposition that they are not. If, then, l differ from x only by an exceeding small quantity, the theorem fails.

In this case the value of the integral is made up of those of its elements which lie immediately about both its limits, all the rest being evanescent. We may then suppose this whole integral to be the sum of two others. Commencing respectively from its limits, and extending each to infinity, it will be represented thus,

$$fl \int_{(l-x)}^{\infty} \frac{\rho dz}{\rho^2 l^2 + \pi^2 z^2} + f-l \int_{-\infty}^{-(l-x)} \frac{-\rho dz}{\rho^2 l^2 + \pi^2 z^2}.$$

whence, since each of the integrals equals $\frac{1}{2}$, we obtain,

$$\frac{1}{2} \{fl + f-l\} = \frac{1}{2l} \int_{-l}^l fx_1 dx_1 + \frac{1}{l} \sum (-1)^n \left\{ \int_{-l}^l \cos \frac{n\pi x_1}{l} fx_1 dx_1 \right\} \dots \dots (3.).$$

Comparing this equation with equation (2.) it is manifest that the latter fails when $l = x$, except the form of the function be such that $fl = f-l$.

The function fx is entirely arbitrary, it is not even subject to the law of continuity: thus we may suppose fx to have certain finite values during that portion of its transition from $f-l$ to fl , which lies between the limits $f\lambda$ and $f\lambda'$, and to be evanescent without those limits, the integral being thus to be taken between the limits λ and λ' instead of l and $-l$. But it is important to observe, that for the values $x = \lambda$ and $x = \lambda'$ the theorem will fail, the actual value of fx being one half of that which is given by it. In the demonstration of it, x , about which the finite value of the integral is found, is supposed to lie between the limits of integration, the integral includes, therefore, elements which lie in both directions, positively and negatively from x , and which constitute each one half of the whole integral; but when x does not lie between these limits, but coincides with one of them, the integral embraces only the elements which lie in one direction from it, the others being without the limits of integration, and therefore evanescent. Thus the integral is in this particular case one half the general integral.

Let us now suppose that fx vanishes for all negative values of x , including $-l$, but that it does not vanish for the positive values between 0 and l . The theorem then becomes

$$fx = \frac{1}{2l} \int_0^l fx_1 dx_1 + \frac{1}{l} \sum_1^n \left\{ \int_0^l \cos \frac{n\pi(x-x_1)}{l} fx_1 dx_1 \right\}.$$

Replacing x by $-x$ we have

$$0 = \frac{1}{2l} \int_0^l fx_1 dx_1 + \frac{1}{l} \sum_1^n \left\{ \int_0^l \cos \frac{n\pi(x+x_1)}{l} fx_1 dx_1 \right\}.$$

* *Théorie Mathématique de la Chaleur*, p. 188.

Definite
Integrals.

Adding these equations, and subtracting them,

$$fx = \frac{1}{l} \int_0^l f x_1 dx_1 + \frac{2}{l} \sum \left\{ \int_0^l \cos \frac{n\pi x_1}{l} f x_1 dx_1 \right\} \cos \frac{n\pi x}{l} \dots \dots (4.),$$

$$fx = \frac{2}{l} \sum \left\{ \int_0^l \sin \frac{n\pi x_1}{l} f x_1 dx_1 \right\} \sin \frac{n\pi x}{l} \dots \dots (5.).$$

 These two equations constitute the theorem of LAGRANGE, given in the third volume of the *Anciens Mém. de Turin*.

 In equation (2.) the limits l and $-l$ may be as great as we please. Let them be infinite. The second member of that equation will then represent the function fx for all real values of x from $-\infty$ to $+\infty$. Moreover, the first term of it will vanish by reason of the infinite divisor l , and the second term may be written under the form

$$\frac{1}{\pi} \sum_1 \int_{-l}^l \cos \left(\frac{n\pi}{l} \right) (x - x_1) \cdot f x_1 \cdot \left(\frac{\pi}{l} \right) dx_1.$$

 If, therefore, we write the infinitesimal quantity $\left(\frac{\pi}{l} \right) = d\alpha$, and $n \frac{\pi}{l} = \alpha$, the symbol $\sum_1$ will become $\int_0^\infty$, and we shall have

$$fx = \frac{1}{\pi} \int_0^\infty \int_{-\infty}^{+\infty} \cos \alpha (x - x_1) f x_1 d\alpha dx_1 \dots \dots (6.).$$

which is FOURIER'S celebrated theorem. (See CALCULUS OF FUNCTIONS, art. 225.)

 This theorem being in point of fact embraced under the preceding theorem of Poisson, the method of its application is the same. Thus to apply it to a given function fx of x , whose value it is required to determine between certain given limits, it must be converted into a discontinuous function, evanescent beyond certain other arbitrary limits including these, and the integration $\int_{-\infty}^{+\infty}$ then made in respect to these arbitrary limits instead of $-\infty$ and $+\infty$: and, in general, the integration is not in any case to be made in respect to these infinite limits, unless the arbitrary limits spoken of above, beyond which the function is evanescent, be themselves infinite.

The following example may serve as a verification of the theorem:

 Let $fx = x$, and let x be supposed to be evanescent beyond the limits λ and λ' , therefore, by the theorem of Fourier,

$$x = \frac{1}{\pi} \int_0^\infty \int_\lambda^{\lambda'} x_1 \cos \alpha (x - x_1) d\alpha dx_1.$$

$$\text{Now } \int_\lambda^{\lambda'} x_1 \cos \alpha (x - x_1) dx_1 = -\frac{\lambda'}{\alpha} \sin \alpha (x - \lambda') + \frac{\lambda}{\alpha} \sin \alpha (x - \lambda) + \frac{1}{\alpha^2} \{ \cos \alpha (x - \lambda') - 1 \} - \frac{1}{\alpha^2} \{ \cos \alpha (x - \lambda) - 1 \};$$

also

$$\int_0^\infty \frac{\sin \mu \alpha}{\alpha} d\alpha = \frac{1}{2} \pi;$$

 and multiplying by $d\mu$, and integrating in respect to μ , under the sign of integration in respect to α , we have, taking the integral from 0 to μ ,

$$\int_0^\infty \frac{\cos \mu \alpha - 1}{\alpha^2} d\alpha = -\frac{1}{2} \pi \alpha.$$

 Applying then these formulæ to the preceding integration $(x - \lambda)$, and $(x - \lambda')$ being substituted successively for μ , we get

$$\frac{1}{\pi} \int_0^\infty \int_\lambda^{\lambda'} x_1 \cos \alpha (x - x_1) dx_1 d\alpha = \frac{1}{2} \lambda' + \frac{1}{2} \lambda + \frac{1}{2} (x - \lambda') + \frac{1}{2} (x - \lambda).$$

 Now the second member of this equation reduces itself to x , and thus the theorem is verified.

SECTION IX.

ON THE VALUES OF CERTAIN DEFINITE INTEGRALS DETERMINED BY THE METHOD OF INTEGRATION OR DIFFERENTIATION IN RESPECT TO AN ARBITRARY CONSTANT UNDER THE SIGN OF INTEGRATION.

 Let u be any function of x , involving the arbitrary constant α ;

$$\therefore \frac{d \int u dx}{dx} = u; \therefore \frac{d^2 \int u dx}{dx d\alpha} = \frac{du}{d\alpha}; \therefore \frac{d^3 \int u dx}{d\alpha^2 dx} = \frac{d^2 u}{d\alpha^2}; \therefore \frac{d \int u dx}{d\alpha} = \int \frac{du}{d\alpha} dx \dots \dots (1.);$$

 that is, the integral $\int u dx$ is differentiated in respect to α , when u is differentiated under the sign of integration in respect to α . In the last equation, for u substitute $\int u d\alpha$;

$$\therefore \frac{d \int \{ \int u d\alpha \} dx}{d\alpha} = \int u dx.$$

Integrating

$$\int \{ \int u d\alpha \} dx = \int \{ \int u dx \} d\alpha \dots \dots (2.),$$

 Definite
Integrals.

Definite Integrals. that is, the integral $\int u dx$ is integrated in respect to α when u is integrated under the sign of integration in respect to α . *Definite Integrals.* The above processes of integration and differentiation proved of the general integral are necessarily true of the definite integral, and proved of the first orders of integration and differentiation, they are necessarily true of every other.

By means of them we may, from the known integral of one function between certain limits, determine the integrals of an infinite number of others between the same limits,

Thus, let $\int_a^b u dx = A$, A being given, and let u_n , A_n , $u^{(n)}$, $A^{(n)}$ represent respectively the n th integrals, and the n th differential coefficients of u and A in respect to the arbitrary constant α ; then will

$$\int_a^b u_n dx = A_n, \text{ and } \int_a^b u^{(n)} dx = A^{(n)}.$$

EXAMPLE 1.

$$\int_0^a (a^2 - x^2)^{-\frac{1}{2}} dx = \frac{a\pi}{2}.$$

Differentiating with respect to a n times,

$$\int_0^a (a^2 - x^2)^{-\frac{2n+1}{2}} dx = -\frac{\pi}{2(2n-1)a^{2n-1}}.$$

EXAMPLE 2.

$$\int_0^1 x^{m-1} dx = \frac{1}{m}.$$

Integrating with respect to m under the sign of integration,

$$\int_0^1 \left\{ \frac{x^m}{\log x} + C \right\} = \log m;$$

whence since when $m=1$ $\log m=0$; $\therefore C = \frac{-1}{\log x}$; $\therefore \int_0^1 \frac{x^m - 1}{\log x} = \log m$.

Another application of this method of differentiating and integrating under the sign of integration is the following.

Let $\int_a^b u dx$ be assumed $= A$, and let this equation be n times differentiated in respect to the arbitrary constant

α . It may occur that, between two or more of the resulting equations, the integrals $\int_a^b \frac{d^n u}{da^n} dx$, &c., which enter into these, may eliminate. A differential equation will then be obtained in A on the solution of which the determination of the value of the proposed integral will have been made to depend.

EXAMPLE 3. To determine the definite integral $\int_0^\infty \epsilon^{-x^2 - \frac{a^2}{x^2}} dx$ assume it $= A$, then differentiating with respect to a ,

$$\frac{dA}{da} = -2 \int_0^\infty \epsilon^{-x^2 - \frac{a^2}{x^2}} \cdot \frac{a}{x^2} dx = -2 \int_0^\infty \epsilon^{-\left(\frac{a}{x}\right)^2 - \left(\frac{a}{x}\right)^2} \cdot d\left(\frac{a}{x}\right),$$

or

$$\frac{dA}{da} = -2A; \therefore A = C \epsilon^{-2a}.$$

To determine C , let $a=0$; $\therefore C = A_0 = \int_0^\infty \epsilon^{-x^2} dx = \frac{1}{2} \sqrt{\pi}$ (equation (16.), Section VI.);

$$\therefore \int_0^\infty \epsilon^{-x^2 - \frac{a^2}{x^2}} dx = \frac{1}{2} \sqrt{\pi} \epsilon^{-2a}.$$

EXAMPLE 4. To determine the definite integral

$$\int_0^\infty \epsilon^{-x^n - \frac{ba^n}{x^n}} dx,$$

under which form is included the preceding. Assume it $= A$: differentiating twice with respect to a ,

$$\frac{d^2 A}{da^2} = -n(n-1)ba^{n-2} \int_0^\infty \epsilon^{-x^n - \frac{ba^n}{x^n}} \cdot \frac{dx}{x^n} + n^2 b^2 a^{2n-2} \int_0^\infty \epsilon^{-x^n - \frac{ba^n}{x^n}} \cdot \frac{dx}{x^{2n}}.$$

But integrating by parts we obtain

$$\int_0^\infty \epsilon^{-x^n - \frac{ba^n}{x^n}} \cdot \frac{dx}{x^{2n}} = \frac{1}{nba^n x^{n-1}} \cdot \epsilon^{-x^n - \frac{ba^n}{x^n}} + \frac{1}{ba^n} \int_0^\infty \epsilon^{-x^n - \frac{ba^n}{x^n}} dx + \frac{n-1}{nba^n} \int_0^\infty \epsilon^{-x^n - \frac{ba^n}{x^n}} \cdot \frac{dx}{x^n}.$$

Also the term without the integral sign vanishes for both of the limiting values of x , 0 and ∞ ;

Definite Integrals.

Definite Integrals.

$$\therefore \int_0^{\infty} \epsilon^{-x^n - \frac{ba^n}{x^n}} \frac{dx}{x^{2n}} = \frac{1}{ba^n} \int_0^{\infty} \epsilon^{-x^n - \frac{ba^n}{x^n}} dx + \frac{n-1}{nba^n} \int_0^{\infty} \epsilon^{-x^n - \frac{ba^n}{x^n}} \cdot \frac{dx}{x^n}.$$

$$\frac{d^2 A}{da^2} = n^2 ba^{n-2} \cdot A \dots \dots (3.).$$

 $\therefore$ eliminating,

On the integration of which differential equation the value of the proposed integral is made to depend.

 To reduce it to an equation of the first order, let A be assumed $= \epsilon^{fRda}$;

$$\therefore \frac{d^2 A}{da^2} = \left(\frac{dR}{da} + R^2 \right) \epsilon^{fRda};$$

 $\therefore$ by equation (3.)

$$\frac{dR}{da} + R^2 = n^2 ba^{n-2} \dots \dots (4.);$$

 which is the equation well known by the name of Riccati's equation, integrable under a finite form by the ordinary methods, when $n-2 = \frac{-4i}{2i \pm 1}$, where i is any positive integer. The value of the proposed definite integral

 may therefore always be determined whenever n is included under the form $\frac{2}{1 \pm 2i}$.

 For a yet more general integral, of which this is a particular case, the reader may see Euler, *Calcul Integral*, chapter ix. and x.

EXAMPLE 5. To determine the values of the integrals

$$\int_0^{\infty} \epsilon^{-bx} \cdot \cos ax \cdot x^{n-1} dx, \text{ and } \int_0^{\infty} \epsilon^{-bx} \cdot \sin ax \cdot x^n \cdot ax,$$

let the first integral be represented by A, and the second by B;

$$\therefore \frac{dA}{da} = - \int_0^{\infty} \epsilon^{-bx} \cdot \sin ax \cdot x^n \cdot dx$$

$$\frac{dB}{da} = \int_0^{\infty} \epsilon^{-bx} \cdot \cos ax \cdot x^n \cdot dx.$$

And integrating by parts,

$$\int \epsilon^{-bx} \sin ax x^n dx = -\frac{1}{b} \epsilon^{-bx} \sin ax x^n + \frac{a}{b} \int \epsilon^{-bx} \cos ax x^n dx + \frac{n}{b} \int \epsilon^{-bx} \sin ax x^{n-1} dx,$$

$$\int \epsilon^{-bx} \cos ax x^n dx = -\frac{1}{b} \epsilon^{-bx} \cos ax x^n - \frac{a}{b} \int \epsilon^{-bx} \sin ax x^n dx + \frac{n}{b} \int \epsilon^{-bx} \cos ax x^{n-1} dx.$$

 Now the exponents b and n being supposed positive, the first terms of the second members of each of these equations vanish for the values of x , 0, and ∞ . They become, therefore, by substitution,

$$\left. \begin{aligned} \frac{dA}{da} &= \frac{a}{b} \frac{dB}{da} + \frac{n}{b} B \\ \frac{dB}{da} &= \frac{a}{b} \frac{dA}{da} + \frac{n}{b} A \end{aligned} \right\} \dots \dots (5.).$$

Eliminating B between these equations we have

$$\frac{d(a^2 + b^2) \frac{dA}{da}}{da} + 2na \frac{dA}{da} + (n + n^2) A = 0$$

 Assuming in this equation $A = (b^2 + a^2)^m R$, and $\tan^{-1} \frac{a}{b} = \alpha$, we shall obtain ultimately, by substitution and reduction,

$$b^2 \frac{d^2 R}{d\alpha^2} + (2n + 4m) ba \frac{dR}{d\alpha} + \{ (n + n^2 + 2m) b^2 + (n + 2m)(1 + n + 2m) a^2 \} R = 0;$$

 in which equation, if we assume $m = -\frac{1}{2}n$, we shall obtain

$$\frac{d^2 R}{d\alpha^2} + n^2 R = 0 \dots \dots (6.);$$

whence by the known methods

$$R = C_1 \cos n\alpha + C_2 \sin n\alpha;$$

$$\therefore A = \frac{C_1 \cos n\alpha + C_2 \sin n\alpha}{(a^2 + b^2)^{\frac{n}{2}}}.$$

 To determine C_1 and C_2 let α be made $= 0$ in the values of A and $\frac{dA}{da}$;

Definite
Integrals.

$$\therefore A_0 = C_1 b^{-n}, \quad \left(\frac{dA}{da} \right)_0 = C_2 n b^{-n}.$$

Definite
Integrals.

Now

$$A_0 = \int_0^{\infty} e^{-bx} x^{n-1} dx,$$

$$\left(\frac{dA}{da} \right)_0 = 0;$$

$$\therefore C_1 = b^n \int_0^{\infty} e^{-bx} x^{n-1} dx = \int_0^{\infty} e^{-bx} (bx)^{n-1} dbx = - \int_0^{\infty} \left\{ \log \frac{1}{bx} \right\}^{n-1} dbx = \int_0^{\infty} \left\{ \log \frac{1}{bx} \right\}^{n-1} dbx = \Gamma n C_2 = 0;$$

$$\therefore \int_0^{\infty} e^{-bx} \cos ax \cdot x^{n-1} dx = \frac{\cos \left\{ n \tan^{-1} \frac{a}{b} \right\}}{(a^2 + b^2)^{\frac{n}{2}}} \Gamma n \dots \dots (7.).$$

Eliminating $\frac{dB}{da}$ between equations (5.), and substituting for A and $\frac{dA}{da}$, we obtain

$$\int_0^{\infty} e^{-bx} \sin ax \cdot x^{n-1} dx = \frac{\sin \left\{ n \tan^{-1} \frac{a}{b} \right\}}{(a^2 + b^2)^{\frac{n}{2}}} \Gamma n \dots \dots (8.).$$

Let $b=0$, and $n=1$;

$$\therefore \int_0^{\infty} \cos ax \, dx = \frac{\cos \frac{\pi}{2}}{a} \Gamma 1 = 0$$

$$\int_0^{\infty} \sin ax \, dx = \frac{\sin \frac{\pi}{2}}{a} \Gamma 1 = \frac{1}{a}.$$

These values of $\int_0^a \cos ax \, dx$ and $\int_0^a \sin ax \, dx$ are to be considered as limits of the values of $\int_0^{\infty} e^{-bx} \cos ax \cdot x^{n-1} dx$ and $\int_0^{\infty} e^{-bx} \sin ax \cdot x^{n-1} dx$. The integrals of periodical functions, such as $\cos ax$ and $\sin ax$, which extend to infinity, can in no case have any other interpretation than as the limits of other integrals whose elements continually diminish, and in their infinite state vanish.

EXAMPLE 6. To determine a differential equation on the solution of which the integral

$$\int_0^{\infty} \frac{\cos ax \, dx}{A + Bx^2 + Cx^4 + \dots + x^{2n}}$$

may be made to depend.

Assume this integral to be represented by u ; and let the denominator be supposed not to vanish for any real value of x , so that the integral may not become infinite between the values of x , 0, and ∞ . Differentiating the proposed integral twice, four times, &c., $2n$ times in respect to a , and multiplying successively by $+A$, $-B$, $+C$, $-D$, &c., the denominator will, by the addition of the resulting equations, disappear, and we shall obtain the equation

$$Au - B \frac{d^2 u}{da^2} + C \frac{d^4 u}{da^4} - D \frac{d^6 u}{da^6} + \dots \pm \frac{d^{2n} u}{da^{2n}} = \int_0^{\infty} \cos ax \, dx.$$

But it has been shown that

$$\int_0^{\infty} \cos ax \, dx = 0;$$

$$\therefore Au - B \frac{d^2 u}{da^2} + C \frac{d^4 u}{da^4} - D \frac{d^6 u}{da^6} + \dots \pm \frac{d^{2n} u}{da^{2n}} = 0 \dots \dots (9.).$$

On the solution of which differential equation by the known rules the value of the proposed definite integral is made to depend.

EXAMPLE 7.

$$\text{Let } A = \int_0^{\pi} \frac{\sin^p x \, dx}{(1 - 2a \cos x + a^2)^n};$$

in which a is an arbitrary constant, and p and n any quantities whatever, positive or negative, with this condition, that $p+1$ is positive, without which the value of the integral would be infinite. Differentiating twice with respect to a ,

$$\frac{dA}{da} = 2n \int_0^{\pi} \frac{(\cos x - a) \sin^p x \, dx}{(1 - 2a \cos x + a^2)^{n+1}}$$

$$\frac{d^2 A}{da^2} = 4n(n+1) \int_0^{\pi} \frac{(\cos x - a)^2 \sin^p x \, dx}{(1 - 2a \cos x + a^2)^{n+2}} - 2n \int_0^{\pi} \frac{\sin^p x \, dx}{(1 - 2a \cos x + a^2)^{n+1}}.$$

Now, integrating by parts, we have

Definite
Integrals.

$$\int \frac{\cos x \sin^p x dx}{(1-2a \cos x + a^2)^{n+1}} = \frac{1}{p+1} \frac{\sin^{p+1} x}{(1-2a \cos x + a^2)^{n+1}} + \frac{2(n+1)a}{p+1} \int \frac{\sin^{p+2} x dx}{(1-2a \cos x + a^2)^{n+2}};$$

Definite
Integrals.

and since the first term of the second member vanishes at the limits 0 and π ,

$$\therefore \frac{dA}{da} = \frac{4n(n+1)a}{p+1} \int_0^\pi \frac{\sin^{p+2} x dx}{(1-2a \cos x + a^2)^{n+2}} - 2na \int_0^\pi \frac{\sin^p x dx}{(1-2a \cos x + a^2)^{n+1}}.$$

Multiplying this value of $\frac{dA}{da}$ by $\frac{p+1}{a}$, and adding it to that of $\frac{d^2A}{da^2}$, we have

$$\frac{d^2A}{da^2} + \frac{p+1}{a} \frac{dA}{da} = 2n(2n-p) \int_0^\pi \frac{\sin^p x dx}{(1-2a \cos x + a^2)^{n+1}};$$

also adding the first value of $\frac{dA}{da}$ multiplied by a , to that of A multiplied by n

$$a \frac{dA}{da} + nA = n(1-a^2) \int_0^\pi \frac{\sin^p x dx}{(1-2a \cos x + a^2)^{n+1}}.$$

Eliminating, therefore, the integrals in the two last equations,

$$(1-a^2) \frac{d^2A}{da^2} + \left\{ \frac{p+1}{a} - (4n-p+1)a \right\} \frac{dA}{da} - 2n(2n-p)A = 0. \dots \dots (10.).$$

On the solution of which differential equation depends the value of the definite integral under consideration. We shall here confine ourselves to the discussion of a case in which this equation presents itself under a form readily integrable, referring the reader for the discussion of other integrable cases to the paper of Poisson, in the tenth volume of the *Journal de l'Ecole Polytechnique*.

Let $p=2n$; $\therefore \frac{d^2A}{da^2} + \frac{2n+1}{a} \frac{dA}{da} = 0$, whose integral is $A = C_1 + C_2 a^{-2n}$.

In the determination of the arbitrary constants C_1 and C_2 , two cases present themselves. First, that in which $a < 1$, and secondly, that in which $a > 1$. In the first case the proposed integral may be developed in a converging series, ascending by whole and positive powers of a ; in the second case the series will descend by the powers of $a-2n, -2n-1, -2n-2$, &c., in which no power can equal zero. From this it follows that in the first case no term or terms of the expanded integral can equal $C_2 a^{-2n}$, or $C_2 a^{-p}$ - p being essentially negative or a fraction; and that in the second case no term can equal $C_1 a^0$; so that in the first case C_2 must equal 0, and in the second, C_1 must equal 0;

$$\therefore \text{in the first case, } \int_0^\pi \frac{\sin^{2n} x dx}{(1-2a \cos x + a^2)^{2n}} = C_1; \text{ and in the second case, } \int_0^\pi \frac{\sin^{2n} x dx}{(1-2a \cos x + a^2)^{2n}} = C_2 a^{-2n}.$$

Also making in the first integral $a=0$, we have $\int_0^\pi \sin^{2n} x dx = C_1$; and making in the second $a = \infty$, $\int_0^\pi \sin^{2n} x dx = C_2$.

$$\text{In the first case therefore } \int_0^\pi \frac{\sin^{2n} x dx}{(1-2a \cos x + a^2)^{2n}} = \int_0^\pi \sin^{2n} x dx = \frac{1.3 \dots (2n-1)}{2.4 \dots 2n} \pi.$$

$$\text{The second case } \int_0^\pi \frac{\sin^{2n} x dx}{(1-2a \cos x + a^2)^{2n}} = a^{-2n} \int_0^\pi \sin^{2n} x dx = \frac{1.3 \dots (2n-1)}{2.4 \dots 2n} a^{-2n} \pi.$$

SECTION X.

ULTRA ELLIPTIC FUNCTIONS.

Elliptic functions, properly so called, and ultra elliptic functions, are included in common under the formula

$$\int_0^{x_1} \frac{fx dx}{(x-\alpha)\sqrt{\phi x}}.$$

where fx and ϕx are rational functions of x .

If the dimensions of ϕx be not less than 3, this formula represents an ULTRA ELLIPTIC FUNCTION.

An ultra elliptic function is said to be of the n th class when the dimensions of ϕx are represented by the formulæ $2n+1$, or $2n+2$.

In the formula

$$C \frac{1}{x} \frac{\Psi x fx}{x-\alpha} - \Psi_\alpha . fx + C \dots \dots (1.),$$

which, by ABEL'S THEOREM (Section II., page 499), represents the sum $\sum \pm \psi x$ of any number of elliptic or ultra elliptic functions; the second term may vanish, fx being of the form $(x-\alpha)f_1x$, so that $fx=0$. Moreover, the first term may vanish, $\frac{1}{x}$ not entering in the first power into the expansion of $\frac{\Psi fx}{x-\alpha}$ according to the powers of $\left(\frac{1}{x}\right)$.

Thus the two first terms of the formula may vanish, and the theorem of Abel reduce itself to

$$\sum \pm \psi x = C; \quad 3 \text{ z } 2$$

Definite
Integrals.

or the second term only may vanish, and the equation become

$$\Sigma \pm \psi x = C \frac{1}{x} \frac{\Psi x f x}{x-a} + C;$$

Definite
Integrals.or neither of the terms of the equation may vanish, but fx may represent unity, in which case

$$\Sigma \pm \psi x = C \frac{1}{x} \frac{\Psi x}{x-a} - \Psi a + C.$$

All elliptic and ultra elliptic functions are included under some one of these three cases, or are reducible to others included under them; and, as they are included under the first, the second, or the third case, they are said to be of the FIRST, the SECOND, or the THIRD ORDERS; a division analogous to that of ordinary elliptic functions, and, indeed, including it.

To determine under what circumstances the term $C \frac{1}{x} \frac{\Psi x f x}{x-a}$ is evanescent.

$$\Psi x = \frac{1}{\sqrt{\phi x}} \log. \left\{ \frac{1 + \frac{\theta_2 x (\phi_2 x)^{\frac{1}{2}}}{\theta_1 x (\phi_1 x)^{\frac{1}{2}}}}{1 - \frac{\theta_2 x (\phi_2 x)^{\frac{1}{2}}}{\theta_1 x (\phi_1 x)^{\frac{1}{2}}}} \right\}.$$

This equation may be expanded under the form

$$\Psi x = \frac{2}{\phi_2 x} \sum_1^{\infty} \frac{1}{2N-1} \left(\frac{\theta_2 x}{\theta_1 x} \right)^{(2N-1)} \cdot \left(\frac{\phi_2 x}{\phi_1 x} \right)^N$$

the values of N being taken from unity to infinity.

$$\text{Now } \frac{\theta_2 x}{\theta_1 x} = \frac{x^{n_2} \left\{ l_2 + k_2 \left(\frac{1}{x} \right) + \dots + a_2 \left(\frac{1}{x} \right)^{n_2} \right\}}{x^{n_1} \left\{ l_1 + k_1 \left(\frac{1}{x} \right) + \dots + a_1 \left(\frac{1}{x} \right)^{n_1} \right\}} = \left(\frac{1}{x} \right)^{n_1 - n_2} \odot \frac{1}{x},$$

where $\odot \frac{1}{x}$ is a function ascending by powers of $\frac{1}{x}$ from $\left(\frac{1}{x} \right)^0$ and n_1, n_2 are the dimensions of $\theta_1 x, \theta_2 x$.

Similarly, if m_1, m_2 be the dimensions of $\phi_1 x, \phi_2 x$, $\frac{\phi_2 x}{\phi_1 x} = \left(\frac{1}{x} \right)^{m_1 - m_2} \Phi \frac{1}{x}$,

where $\Phi \frac{1}{x}$ is a function ascending by powers of $\frac{1}{x}$ from $\left(\frac{1}{x} \right)^0$;

$$\therefore \left(\frac{\theta_2 x}{\theta_1 x} \right)^{2N-1} \left(\frac{\phi_2 x}{\phi_1 x} \right)^N = \left(\frac{1}{x} \right)^{(2N-1)(n_1 - n_2) + N(m_1 - m_2)} \left\{ \odot \frac{1}{x} \right\} \left\{ \Phi \frac{1}{x} \right\}.$$

Similarly it may be shown that

$$\frac{fx}{(x-a)\phi_2 x} = \left(\frac{1}{x} \right)^{m_2 - f + 1} f_1 \frac{1}{x},$$

where $f_1 \frac{1}{x}$ is a function ascending by powers of $\left(\frac{1}{x} \right)$ from $\left(\frac{1}{x} \right)^0$, and where f represents the dimensions of fx in x ;

$$\therefore C \frac{1}{x} \frac{\Psi x f x}{x-a} = 2 \sum_1^{\infty} \frac{1}{2N-1} \left\{ F \frac{1}{x} \right\} \left(\frac{1}{x} \right)^{(2N-1)(n_1 - n_2) + N(m_1 - m_2) + m_2 - f + 1},$$

where $F \frac{1}{x}$ is a function ascending by powers of $\frac{1}{x}$ from $\left(\frac{1}{x} \right)^0$.

Hence, therefore, it is manifest that the term $C \frac{1}{x} \frac{\Psi x f x}{x-a}$ is evanescent, if, for all positive integral values of N ,

$$(2N-1)(n_1 - n_2) + N(m_1 - m_2) + m_2 - f + 1 > 1;$$

or

$$N \{ 2(n_1 - n_2) + (m_1 - m_2) \} + m_2 + n_2 - (n_1 + f) > 0.$$

And if this inequality do not obtain for all positive integral values of N , then the first term of the formula (1.) is not evanescent.

Now let us suppose that m_1 and n_1 are taken greater than m_2 and n_2 , or equal to them, then, its first term being positive, the inequality will be satisfied for all values of N , if it is satisfied for its first value, unity, or if

$$2(n_1 - n_2) - m_1 - m_2 + m_2 + n_2 - n_1 - f > 0;$$

or if

$$n_1 - n_2 + m_1 - f > 0 \dots \dots (2.).$$

Also, since m_1 and n_1 are greater than m_2 and n_2 , the dimensions of the first member of the equation

$$(\theta_1 x)^2 (\phi_1 x) - (\theta_2 x)^2 (\phi_2 x)^2 (\phi_2 x) = P(x - x_1)$$

Definite
Integrals.

are those of its first term ;

$$\therefore 2n_1 + m_1 = \mu \dots \dots \dots (3.).$$

 Let the difference of the dimensions of the two terms of the first member of the equation be δ

$$\therefore 2n_1 + m_1 = \delta + 2n_2 + m_2.$$

 Eliminating m_1 and m_2 , observing that $m_1 + m_2 = m$, we have

$$\mu = n_1 + n_2 + \frac{m + \delta}{2} \dots \dots \dots (4.).$$

 Eliminating m_1 by means of equation (3.), the inequality (2.) becomes $-(n_1 + n_2) + \mu - f >$, and eliminating $-(n_1 + n_2) + \mu$ by equation (4.), it becomes

$$\frac{m + \delta}{2} - f > 0 \dots \dots \dots (5.).$$

 It is on this inequality, then, that depends ultimately the evanescence of the first term of the formula (1.), provided m_1 and n_1 be assumed greater than m_2 and n_2 .

 Now, fx may, or it may not, be of the form $(x - \alpha) f_1 x$, where $f_1 x$ is a rational function of x .

 If it be of that form, the second term of the formula (1.) will vanish since $f\alpha = 0$.

 Moreover, the evanescence of the first term depends upon the condition expressed by the inequality (5.); or, since we may assume the arbitrary functions $\theta_1 x$ and $\theta_2 x$ of such dimensions that δ may equal 0 or 1, according as m is odd or even (see equation (4.)), it depends upon the inequality

$$\frac{\left(m + \frac{1}{2}\right) \pm \frac{1}{2}}{2} - f > 0 \dots \dots \dots (6.).$$

 fx being of the form $(x - \alpha) f_1 x$, and this inequality obtaining, the two first terms of the formula (1.) will vanish, and the function will be of the FIRST ORDER.

 fx being of the form $(x - \alpha) f_1 x$, and this inequality not obtaining, the second term only of the formula will vanish, and the function will be of the SECOND ORDER.

 Now let us suppose that fx is not of the form $(x - \alpha) f_1 x$.

 Since fx is a rational function of x , therefore $fx - f\alpha$ is of the form $(x - \alpha) f_1 x$.

Let

$$fx - f\alpha = (x - \alpha) f_1 x;$$

$$\therefore fx = f\alpha + (x - \alpha) f_1 x;$$

$$\therefore \phi x = f\alpha \int \frac{dx}{(x - \alpha)\sqrt{\phi x}} + \int \frac{f_1 x \cdot dx}{\sqrt{\phi x}} \dots \dots \dots (7.),$$

 where the integral $\int \frac{dx}{(x - \alpha)\sqrt{\phi x}}$ belongs to the THIRD ORDER of functions, that in which fx equals unity; and the

 integral $\int \frac{f_1 x dx}{\sqrt{\phi x}}$, being of the class in which fx is of the form $(x - \alpha) f_1 x$, has been shown to be the FIRST or

SECOND ORDER. All ultra elliptic functions are therefore reducible to one of these three orders of functions.

 From equation (7.) it appears that when $f\alpha = 0$ any function of the form $\int \frac{f_1 x dx}{(x - \alpha)\sqrt{\phi x}}$ may be made to de-

 pend upon another of the form $\int \frac{f_1 x \cdot dx}{\sqrt{\phi x}}$.

 Now, any integral included under the last of these forms, in which the dimensions of $f_0 x$ are greater than $m - 1$, m being the dimensions of ϕx , may be made to depend upon another or others in which the dimensions of $f_1 x$ are less than $m - 1$. For let M be a multinomial of m' dimensions;

$$\therefore \frac{d\{M\sqrt{\phi x}\}}{dx} = \frac{\left(\frac{dM}{dx}\right)\phi x + \frac{1}{2}\left(\frac{d\phi x}{dx}\right)}{\sqrt{\phi x}};$$

 of which the numerator is of $m + m' - 1$ dimensions. Now the coefficients of the multinomial M which enter into this expression are $m' + 1$ in number; these may therefore be so taken as to cause $m' + 1$ of its terms to vanish and to give it the form

$$\frac{d\{M\sqrt{\phi x}\}}{dx} \{x^{m+m'-1} - A_{m-2}x_{m-2} - A_{m-3}x_{m-3} - \dots - A_1x - A_0\} \frac{1}{\sqrt{\phi x}}.$$

Let

$$\int \frac{x^m dx}{\sqrt{\phi x}} = \psi_m \text{ and } m + m' - 1 = \lambda;$$

$$\therefore M\sqrt{\phi x} = \psi_\lambda - A_{m-2}\psi_{m-2} - A_{m-3}\psi_{m-3} - \dots - A_1\psi_1 - A_0\psi_0;$$

$$\therefore \psi_\lambda = M\sqrt{\phi x} + A_{m-2}\psi_{m-2} + A_{m-3}\psi_{m-3} + \dots + A_1\psi_1 + A_0\psi_0;$$

 that is, a function ψ_λ , or $\int \frac{x^\lambda dx}{\sqrt{\phi x}}$, in which λ is equal to or greater than $(m - 1)$, the dimensions of ϕx diminished

 Definite
Integrals.

Definite
Integrals.

by unity, may be made to depend upon other similar functions $\psi_{m-2}, \psi_{m-3}, \dots, \psi_1, \psi_0$, in which λ is less than $m-1$. Now any integral of the form $\int \frac{f_1 x}{\sqrt{\phi x}}$, in which $f_1 x$ is a rational function of x , may be supposed to be

Definite
Integrals.

made up of terms of the form $\int \frac{x^\lambda dx}{\sqrt{\phi x}}$. Any such function then, which may be made to depend upon others in which the dimensions of fx are less than those of ϕx diminished by unity.

Now if any function ψx be of the n th class of ultra elliptic functions, $2n+1$ or $2n+2$ are the dimensions of ϕx in that function, according as these are odd or even. Every such function may then be made to depend upon others of the form $\int \frac{f_1 x dx}{\sqrt{\phi x}}$, in which the dimensions of $f_1 x$ are less than $2n$ or $2n+1$, and since $f\alpha=0$, it is a function of the first or second order. The inequality (6.) becomes then, in either case,

$$\frac{2n+2}{2} - f > 0,$$

or

$$n+1 > f.$$

and on this condition it depends whether a function of the n th class, in which $f\alpha=0$, be of the first or second order of functions.

The least number of terms which can compose the sum $\sum \pm \psi x$ appears by equation (4.) to be that for which n_1 and n_2 are each zero, or $\theta_1 x$ and $\theta_2 x$ reduce themselves to constants, and for which δ is zero or unity, according as m is even or odd. This least value is therefore $\frac{m}{2}$ or $\frac{m+1}{2}$. Greater than this μ may be of any value, the

proper dimensions being given to $\theta_1 x$ and $\theta_2 x$. The equation $(\theta_1 x)^2 (\phi_1 x) - (\theta_2 x)^2 (\phi_2 x) = \mathbf{P}(x-x_1 \dots \dots \dots 8.)$

determines the n_1+1 coefficients of $\theta_1 x$, and the n_2+1 coefficients of $\theta_2 x$ in terms of the quantities $x_1, x_2, \dots, x_\mu$ by μ equations obtained by equating the coefficients of like powers of x , there remain then $\mu - n_1 - n_2 - 2$ equations between the μ quantities $x_1, x_2, \dots, x_\mu$ themselves, $n_1 + n_2 + 2$ of which are therefore indeterminate. By equation (4.) it appears that the number of equations of condition may be represented by $\frac{m+\delta}{2} - 2$.

As an application of the theorem of Abel to the theory of ultra elliptic functions, let us take the following example of a function of the second class.

$$\text{Let } \psi x = \int \frac{dx}{\sqrt{1-x^5}}. \text{ Now } 1-x^5 = \left(1+x \frac{\sqrt{5}-1}{2} + x^2\right) \left(1-x \frac{\sqrt{5}-1}{2} + x^2\right) (1-x).$$

$$\text{Assume } \therefore \phi_1 x = \left(1-x \frac{\sqrt{5}-1}{2} + x^2\right) (1-x) = 1-x \frac{\sqrt{5}+1}{2} + x^2 \frac{\sqrt{5}+1}{2} - x^3, \text{ and } \phi_2 x = 1+x \frac{\sqrt{5}+1}{2} + x^2,$$

let

$$\theta_1 x = a+x \quad \theta_2 x = b+cx.$$

In this case $fx=(x-\alpha)$; $\therefore f\alpha=0$; also $m=5$ $f=1$; therefore by the inequality (5.) it appears that

$\mathbf{C} \frac{f_1 x \psi x}{x-\alpha}$ is evanescent. Thus the function is of the first order, and $\sum \pm \phi x = C$.

To determine the conditions necessary to this relation of the functions ψx we have by (8.)

$$(a+x) \left(1-x \frac{\sqrt{5}+1}{2} + x^2 \frac{\sqrt{5}-1}{2} - x^3\right) - (b+cx)^2 \left(1+x \frac{\sqrt{5}+1}{2} + x^2\right) \\ = (x-x_1)(x-x_2)(x-x_3)(x-x_4)(x-x_5) \dots \dots \dots (9.)$$

Equating the coefficients on both sides of this equation, we shall obtain five equations of condition, three of which will determine the constants a and b , and c , in terms of x_1, x_2, x_3, x_4, x_5 , and there will remain two equations of condition between these last five quantities. Three of these five quantities are, therefore, indeterminate; let them be $\frac{1}{2}, 1, -2$;

$$\therefore (a+x)^2 \left(1-x \frac{\sqrt{5}+1}{2} + x^2 \frac{\sqrt{5}-1}{2} - x^3\right) - (b+cx)^2 \left(1+x \frac{\sqrt{5}+1}{2} + x^2\right) = (x-x_1)(x-x_2) \left(x-\frac{1}{2}\right) (x-1)(x+2).$$

It is required from this equation to determine the values of x_1, x_2 in terms of the given values of x_3, x_4, x_5 , whence will be known all the functions which enter into the sum $\sum \psi x$, and also the constants a, b, c ; thus the functions $\theta_1 x$ and $\theta_2 x$ will be determined, and from these the signs with which the different terms enter into that sum. Assuming in the above equation $x=1$, there results the condition $b+c=0$. Hence, substituting for c , and dividing by $1-x$, we obtain the equation

$$(a+x)^2 \left(1-x \frac{\sqrt{5}-1}{2} + x^2\right) - b^2 \left(1+x \frac{\sqrt{5}+1}{2} + x^2\right) = (x-x_1)(x-x_2) \left(x-\frac{1}{2}\right) (x+2).$$

Assuming in this equation $x=\frac{1}{2}$, and $x=-2$,

Definite
Integrals.

$$\frac{1}{2} b^2 (6 + \sqrt{5}) - \left(a + \frac{1}{2}\right)^2 (6 - \sqrt{5}) = 0, \quad 3 b^2 (4 - \sqrt{5}) - (a - 2)^2 (4 + \sqrt{5}) = 0.$$

Definite
Integrals.

From these equations we obtain $a = 20.45345 \dots$, and $b = 20.03253 \dots$. Moreover, equating the coefficients of x^3 and x^0 , there result the equations $b^2 + \frac{\sqrt{5}-1}{2} - 2a = x_1 + x_2 + \frac{1}{2} - 2$ and $b^2 - a^2 = x_1 x_2$; whence we have $x_1 + x_2 = -440.08338$, &c., $x_1 x_2 = -17.04939$, &c.; $\therefore x_1 = 0.03873 \dots$, $x_2 = -440.12211 \dots$.

All the values of x entering into the sum $\sum \pm \psi x$ are now known. It remains only to determine the signs of the several terms of this sum. These are determined (see p. 499) by the sign of the fraction $\frac{\theta_1 x}{\theta_2 x}$, or in this case by the sign of $\frac{a+x}{b(1-x)}$ for each particular value of x ; or substituting the values of a and b by the sign of $\frac{20.45345, \&c. + x}{(20.03253, \&c.) (1-x)}$.

Giving to x the three supposed values of $x_1, x_2, x_3, \frac{1}{2}, 1, -2$, this expression is *positive*. It is also positive for the value x_1 of x , but when x_2 is substituted it becomes negative. All the terms of the sum, therefore, are positive, except that involving this value of x ;

$$\therefore \psi(0.03873, \&c.) - \psi(-440.12211 \dots) + \psi \frac{1}{2} + \psi 1 + \psi - 2 = C.$$

Thus the value of the constant C is determined, which satisfies the equation $\psi x_1 - \psi x_2 + \psi x_3 + \psi x_4 + \psi x_5 = C$, for all values of x_1, x_2, x_3, x_4, x_5 , subject to two equations of condition, which equations of condition are determined by equating the coefficients of like powers of x in the equation (9.).

The value of C may be verified by making any other assumption with respect to the indeterminate quantities x_2, x_3, x_4 than that made above, provided only that this assumption give the same signs to the corresponding integrals. If we take these three quantities each equal to zero, the two following values will be obtained for C ; these are *numerically* the same value with the preceding:

$$\begin{aligned} & -\psi(-2.18399 \dots) - \psi(0.56596 \dots) + \psi 0 + \psi 0 + \psi 0, \\ \text{and} \quad & -\psi(-4.52014 \dots) + \psi(-0.71592 \dots) + \psi 0 + \psi 0 + \psi 0. \end{aligned}$$

It is a remarkable fact, observed by Legendre, who has made these calculations,* that this value of C is represented by the transcendent $-\frac{1}{2} \psi - \frac{1}{0}$, and from the laborious solution of a great number of similar examples he has arrived at the conclusion that, however the conditions of the case may be varied in respect to the sum of five functions of the form $\int \frac{dx}{\sqrt{1-x^5}}$, the constant C will be represented numerically by the transcendent $\left(1 \pm \frac{1}{2}\right) \psi\left(-\frac{1}{0}\right)$, or by a transcendent of two terms of which this quantity is one, and $\psi 1$ the other. He has carried the verification of this remarkable fact to ten places of decimals. The following are some of many examples:

$$\begin{aligned} & \psi(0.36491 \dots) - \psi(-3.83087 \dots) - \psi(-2) - \psi(-1) - \psi\left(\frac{1}{2}\right) = \psi(1) - \frac{3}{2} \psi\left(-\frac{1}{0}\right) \\ & -\psi(0.36491 \dots) - \psi(-3.83087 \dots) - \psi(-2) - \psi(-1) + \psi\left(\frac{1}{2}\right) = \psi(1) - \frac{3}{2} \psi\left(-\frac{1}{0}\right) \\ & -\psi(0.13189 \dots) + \psi(-0.87733 \dots) - \psi(-1) - \psi(-2) - \psi\left(\frac{1}{2}\right) = -\frac{1}{2} \psi\left(-\frac{1}{0}\right) \\ & -\psi(-0.20080 \dots) - \psi(-6.88759 \dots) + \psi(-1) + \psi 0 + \psi 0 = -\frac{1}{2} \psi\left(-\frac{1}{0}\right). \end{aligned}$$

Now $\psi 1 = -\cos \frac{\pi}{5} \psi\left(-\frac{1}{0}\right)$. All the values of C may, therefore, be embraced under the formula

$$-\left(1 \pm \frac{1}{2}\right) \cos \frac{\pi}{5} \cdot \psi\left(-\frac{1}{0}\right).$$

NOTE I.

Note on equation (e), page 502.

In this equation it is assumed that, for the three arbitrary positive values of x the positive sign only is to be taken in the sum $\sum \pm \psi x$, and therefore that for these three values, the signs of $\frac{\theta_1 x}{\theta_2 x}$ or $\frac{a_1 + b_1 x}{a_2 + b_2 x}$ are the same. It is

* *Calcul des Fonctions Elliptiques*, third supplement.

Definite
Integrals.

the object of the following note to discuss the circumstances under which this assumption may be made.

Subtracting the two first and the fifth of the equations (page 502) which determined the coefficients a_1, b_1, a_2, b_2 , we have

$$2a_2(a_2+b_2)k'^2 = \pm P_4 \cos \phi - P_4(1 - \sin \phi) \text{ and } 2a_2(a_2-b_2)k'^2 = \pm P_4 \cos \phi - P_4(1 + \sin \phi);$$

$$\therefore \frac{a_2+b_2}{a_2-b_2} = \frac{\pm P_4 \cos \phi - P_4(1 - \sin \phi)}{\pm P_4 \cos \phi - P_4(1 + \sin \phi)}; \quad \therefore \frac{a_2}{b_2} = \frac{\pm 2P_4 \cos \phi - P_4(1 + \sin \phi) - P_4(1 - \sin \phi)}{P_4(1 + \sin \phi) - P_4(1 - \sin \phi)}.$$

Proceeding similarly in respect to the third and sixth, and fourth and sixth equations,

$$\frac{b_1}{a_1} = k \cdot \frac{\pm 2P_4 \Delta \phi - P_4(1 + k \sin \phi) - P_4(1 - k \sin \phi)}{P_4(1 + k \sin \phi) - P_4(1 - k \sin \phi)}.$$

The sign of $\frac{\theta_1 x}{\theta_2 x}$ changes then for different values of x , as does the sign of

$$1+k \cdot \frac{\pm 2P_4 \Delta \phi - P_4(1 + k \sin \phi) - P_4(1 - k \sin \phi)}{P_4(1 + k \sin \phi) - P_4(1 - k \sin \phi)} \cdot x$$

$$1+k \cdot \frac{P_4(1 + \sin \phi) - P_4(1 - \sin \phi)}{\pm 2P_4 \cos \phi - P_4(1 + \sin \phi) - P_4(1 - \sin \phi)},$$

or as $\frac{(1-kx)P_4(1+k \sin \phi) - (1+kx)P_4(1-k \sin \phi) \pm 2kxP_4 \Delta \phi}{-(1-x)P_4(1+\sin \phi) - (1+x)P_4(1-\sin \phi) \pm 2P_4 \cos \phi}$. Hence giving to x any one of its values, $\sin \phi_1$,

as $\frac{\Delta^2 \phi_1 P_3(1+k \sin \phi) - \Delta^2 \phi_1 P_3(1-k \sin \phi) \pm 2k \sin \phi_1 P_4 \Delta \phi}{-\cos^2 \phi_1 P_3(1+\sin \phi) - \cos^2 \phi_1 P_3(1-\sin \phi) \pm 2P_4 \cos \phi},$

or $\left(\frac{k \Delta \phi_1}{\cos \phi_1} \right) \frac{\Delta \phi_1 \{ \Sigma_3 \sin \phi + k^2 P_3 \sin \phi \} \pm P_3 \Delta \phi}{-\cos \phi_1 \{ 1 + k^2 \Sigma_3 P_2 \sin \phi \} \pm P_3 \cos \phi}.$

If in this expression ϕ_1 be replaced in succession by ϕ_2, ϕ_3, ϕ_4 , the symbols P_3, Σ_3 , applying in each case to the three remaining terms, its sign will determine that of the corresponding term in the sum $\Sigma \pm Fk\phi$. Now it is shown, page 502, that the positive sign is to be taken in the last term $\pm P_3 \Delta \phi$ in the numerator of the expression. If, therefore, $\phi_1, \phi_2, \phi_3, \phi_4$ be positive, the numerator is essentially positive, whichever of these quantities be taken; and if in the term $\pm k^2 P_4 \cos \phi$ of the equation of condition (d), page 502, the negative sign be taken, the denominator is essentially negative for all values of ϕ . This negative sign being then taken in equation (d), and the values of ϕ being assumed to be positive, there are no changes of sign in the sum $\Sigma \pm \psi x$.

NOTE 2.

Note on Equation (6.), Section VI.

Assume $x = \varepsilon^{-z}$; $\therefore \Gamma p = \int_0^1 \left\{ \log. \frac{1}{x} \right\}^{p-1} dx = \int_0^\infty \varepsilon^{-z} z^{p-1} dz$;

$$\therefore \Gamma p \cdot \Gamma q = \int_0^\infty \varepsilon^{-z} z^{p-1} dz \cdot \int_0^\infty \varepsilon^{-u} u^{q-1} du = \int_0^\infty \int_0^\infty \varepsilon^{-z-u} z^{p-1} u^{q-1} dz du.$$

Now if the variables u and z of any double integral $\int \int V du dz$ be changed into x and y , it becomes

$$\int \int V \left\{ \left(\frac{du}{dx} \right) \left(\frac{dz}{dy} \right) - \left(\frac{du}{dy} \right) \left(\frac{dz}{dx} \right) \right\} dx dy.$$

Assume then $u+z=y, u=xy$; $\therefore z=(1-x)y$, and $\left(\frac{du}{dx} \right) \left(\frac{dz}{dy} \right) - \left(\frac{du}{dy} \right) \left(\frac{dz}{dx} \right) = y$; $\therefore \int \int V du dz = \int \int Vy dx dy$.

Making these substitutions in the preceding equation, and observing that the values 0 and ∞ of u correspond to the values 0 and ∞ of y , and the values 0 and ∞ of z to the value 1 and 0 of x , we have

$$\Gamma p \cdot \Gamma q = \int_0^\infty \int_0^1 \varepsilon^{-y} (xy)^{p-1} (1-x)^{q-1} y^p dx dy = \int_0^\infty \int_0^1 \varepsilon^{-y} y^{p+q-1} x^{q-1} (1-x)^{p-1} dx dy$$

$$= \int_0^\infty \varepsilon^{-y} y^{p+q-1} dy \cdot \int_0^1 x^{q-1} (1-x)^{p-1} dx = \Gamma(p+q) \cdot [q, p]; \quad \therefore [q, p] = \frac{\Gamma p \cdot \Gamma q}{\Gamma(p+q)}.$$

This demonstration applies to every case in which p and q are positive quantities, or imaginary quantities of which the real part is positive. It is nearly that given by Jacobi, in *Crelle's Journal*, vol. ii. page 307, which moreover differs but little from the method of Poisson, *Journal de l'Ecole Polytechnique*, vol. xii. p. 477. The method of reduction by means of double integrals appears first to have been used by Laplace.

MORAL AND METAPHYSICAL PHILOSOPHY.

Moral and
Metaphy-
sical Phi-
losophy.

Introduction.

EVERY man is surrounded by a world with which he converses by means of his senses. Every man is connected with other men by necessary or by voluntary relationships. Every man exercises a power over things which in bulk and ordinary force are far superior to him, and is influenced by things which are far inferior to him.

A man may ask, What is the order and constitution of the world which I see lying before me? Such an inquiry gives rise to *Physical Philosophy*.

A man may ask, What is the meaning of these bonds by which I am connected with my fellow-men? Some of them it is obvious cannot be broken. I cannot cease by any act of mine to be a brother or a son; but I can act as if I were not in either of these relations. Under what conditions must I live to be in conformity with this position in which I find myself? How may it become a practical contradiction? Such inquiries give rise to *Moral Philosophy*.

A man may ask, What connection subsists between me and the world around me? Am I subject to the same laws which govern it, or to different laws? Are the powers which I exercise akin to those which these things exercise, or have I some peculiar power of my own? If so, in what right and under what conditions do I possess this power? Such questions give rise to *Metaphysical Philosophy*.

Moral Philosophy then commences with an observation of our actual position as men; Metaphysical Philosophy with a comparison of our position with that of the things around us. Both are distinguished from Physical Philosophy, in that both refer primarily to man. But the moral philosopher assumes a position distinct from that of the physical student; the metaphysical philosopher is always seeking to establish such a position. The habits of feeling, and the external circumstances which lead men to reflect on morals, are widely different from those which lead them to become metaphysicians. A desire to find the foundation of our practical life is the great impulse to the moralist. A desire to find the foundation and the limit of our faculties is the great impulse to the metaphysician. All the primary elements of Moral Philosophy are found embodied in laws, manners, political institutions; these give birth in later times to speculations, schools, and systems. The metaphysician endeavours at first to interpret the difficulties which he finds in himself by speculations about the external world, and feels by degrees the necessity of studying the order of human society. But these lines of thought are continually intersecting each other; it is impossible to follow the track of any great moral question without entering into the region of pure Metaphysics. It is impossible even to understand the meaning of the problems in Metaphysics until we have some acquaintance with the grounds of Morality.

We wish to assist our readers in tracing the progress of human thought upon these momentous subjects.

The history of Moral and Metaphysical Philosophy is profoundly interesting; nor will one who engages earnestly in the study find himself at any loss for documents. What he chiefly wants, we conceive, at any rate what it seems most within the power of an Encyclopædia to supply, are some hints as to the right method of using his materials. He may be glad of an outline map, which though very rudely sketched, and only indicating here and there a mountain and a river, may yet give him such a general impression of the country as he could scarcely have obtained from a more minute survey, and may enable him with greater interest to examine particular localities in the company of more learned and critical travellers.

sical Phi-
losophy.

HEBREW PERIOD.

FROM B. C. 1920 TO B. C. 600.

Preliminary Observations.

The early records of the world are contained in the Hebrew Scriptures. These Scriptures appear to trace with much order and clearness the progress of human thought during the period which they embrace. The first conclusion of every one would be, that they were indispensable documents in any sketch of moral and metaphysical inquiries. But his second thought might probably be, that the character which they assume as records of a Divine revelation makes them unsuitable for this purpose. This opinion he will find confirmed by two sets of persons, who take very opposite views of these records. The first affirm that the subjects of which they treat are different from those of the ordinary historian and philosopher; the second affirm that they are merely a part of ordinary history, and that the apparent peculiarities in their style of thought and composition are either not really characteristic of them, or may be accounted for by mere accidents of age or locality. Either of these hypotheses would make these records useless to our work. The first, obviously, by showing that they have no connection with our subject; the second, as certainly, by depriving them of all authority, and showing that the pretensions upon which they are based are spurious. To the common historian they might be serviceable, even upon this last supposition, as stating actual facts, though referring them to a false principle. The moral historian they would only mislead, for every step in the progress of human thought must be erroneously marked, and wrongly connected with that which preceded and followed it. But possibly some reflection may lead us back to our first conclusion. We may notice that the first view is open to this fatal objection,—that it contradicts the writings which it proposes to magnify. Those writings take the utmost pains to convince us, that the persons whose actions they record were like all other men; were engaged in the actual business of life, were sons, fathers, brothers, shepherds, warriors, statesmen. Their feelings,

with a re-
velation.

Moral and
Metaphysical
Philosophy.

thoughts, deeds, are essentially human; the whole history must be rewritten in order to deprive them of that character.

But there is an objection equally destructive of the second hypothesis. It is at war with *facts*. An obscure Syrian tribe, as Voltaire called it, has exercised an amazing influence over the destinies of mankind; over all the feelings, thoughts, and deeds of men; even to the most remote corners of the universe. This is a fact which must be accounted for; you do not surely account for it by saying that there was nothing peculiar in the condition of this tribe. By all the contrivances which you make use of to diminish the wonder of the narrative, you increase the wonder and difficulty of this problem.

This argument would suggest itself to the ordinary reader. Another suggests itself still more strongly to the moral and metaphysical student. The attempt to reduce the Hebrew records to the law of ordinary histories, presumes that those histories are clear and intelligible. This *he* knows not to be the case. A thousand puzzling and perplexing phenomena occur to him at every step of his progress; he feels that he wants some help to the course of thought indicated by the mythology, the poetry, the formal speculations of the people of Greece or Rome. It is, he is persuaded, because the moral and metaphysical peculiarities of these nations have been less studied than the mere events which befell them, that their history has ever been supposed to be the solution of riddles, and not the riddle itself. This thought suggests to him a method of reconciling those two hypotheses, to either of which separately he had found it impossible to assent. If these records should themselves be the key to the solution of the puzzles he meets with elsewhere, it *must* be true, as the first affirm, that these records are in all respects very remarkable and peculiar; it *must* be true, as the last affirm, that they have the closest connection with all other records relating to the life and affairs of men. With this suggestion to guide him, he is led to reconsider the opinion, that the history of a revelation cannot be the history of human thoughts, feelings, and exercises. He perceives that it is true to this extent; philosophy must be the search after wisdom; it must be therefore the formal opposite of wisdom *communicated*, that is to say, of a revelation. But he knows also, that in all common education we communicate information, in order to excite the desires and faculties which receive information. He does not decide the question whether this is the only method of learning; it certainly is the most common. If so, a revelation, though it may not be philosophy, may be the first source of it; and the history of a revelation may contain, not only a series of communications, but also an accurate record of the awakening of thoughts, feelings, and faculties, by those communications. There is nothing impossible or contradictory in this notion; if a revelation be possible, this would seem the most reasonable form of it. On turning to the Jewish records, he finds that it is the actual form of revelation therein exhibited; he finds these records purporting to be the history of the education of a nation by means of a revelation.

We take them to be what they pretend to be. In doing so, we adopt the common faith of our country; we reconcile two opinions, either of which is itself at variance with facts; and we find, as we think we shall show hereafter, the clearest exposition of the history of philosophy in those ages and countries of which

this revelation does not treat. With these arguments to justify it, the assumption we think is not unwarrantable. Every historian must take something for granted, if he adopt a method at all. *He* seems to take least for granted who does not frame an hypothesis, but adopts one; who does not set it up against other hypotheses, but explains them by means of it; and who subjects it to the surest and severest of all tests, by boasting that it will enable him to discover an order in that which is otherwise unconnected, and remove difficulties otherwise inexplicable.

Moral and
Metaphysical
Philosophy.

With the first part of the Mosaic records we have no immediate concern. They are indeed profoundly interesting to the student of philosophy; the questions of which they treat recur at every step of his progress. But it would be an abuse of language to say that these documents, however closely connected with human inquiries, do themselves describe the progress of human inquiry. We reserve the consideration of them, therefore, for a future stage of our history, when we shall have occasion to compare the views of the origin and order of the world; of the early state of man; of his position in reference to nature and to God, which are developed in them, with those which prevailed in other countries and ages. The necessity of such a preface to the history of the chosen nation will be best understood when we understand the object for which they were chosen; nor is it a needless, though a very obvious remark, that these records presume the facts of the subsequent history, and were written for the benefit of a people who believed themselves to be separated from the rest of the world, and adopted into covenant with the God of Abraham, Isaac, and Jacob.

One observation, however, must be deduced from the history of the antediluvian world, in order that the narrative which follows it may be intelligible.

The historian represents mankind to have been divided into two classes: one following nature and inclination, rushing prematurely into political society, inventing mechanical arts, neglecting family relationships; the other abiding in those relationships, and in faith in an unseen Protector and Lord. The confusion of these two races, and the general lawlessness and violence which followed it, is marked as the immediate occasion of the Deluge. The race is preserved in a single family. After the Deluge we observe another step in human progress. The covenant entered into with Noah, as representative of mankind, marks the commencement of a national period; the terms of the covenant exhibit men in their relations to God, to nature, and to each other. The animal world is given up to their use and government, subject to a restriction upon the eating of blood. Men are declared to be mutually responsible for each other's lives, and the feeling of confidence in an unseen Being, who has established these relationships, is called forth and upheld by the promise that He will not henceforth let loose the waters for the destruction of mankind. The historian interrupts the course of his narrative to relate an event illustrating the connection between the new form of society which this covenant established, and the family relationships, for which the former dispensation had been the witness. One of the sons of Noah exposing the drunkenness

Early
history.

Moral and
Metaphy-
sical Phi-
losophy.

of his father, a curse is pronounced upon his descendants, which the Jews, who knew the character of the people on whom it had fallen, were well able to understand as a solemn declaration that every race among whom the parental relation is not respected, becomes inevitably "a servant of servants."

Under this promise, and with this warning, the descendants of Noah go forth to colonize the earth, after their families, after their tongues, in their lands, after their nations; words clearly indicating that the establishment of national societies, each having a distinct language, and preserving their family relationships, was the purpose contemplated in this dispensation, and was not, as has been strangely imagined, the effect of that rebellion against the Divine order, of which the first recorded manifestation took place on the plain of Shinar. That event is so simple in itself, and so simply told, so exactly suitable to the age of the world in which the scene is laid, that no wise man could ever have fancied it to be a mere allegory, if other men had not as perversely overlooked the principles which the fact involves in controversies about the fact itself. That the ground of all human society is laid in faith on an unseen Being, that by this faith man is raised above his own animal nature and the animal natures which surround him, that by this he is preserved from the fear of the grand objects and operations of nature, which are continually passing before his eyes in the heaven above and the earth beneath;—this is the principle of that covenant of which we have been speaking, the principle of the whole Bible, the principle on which we shall find all history, and the history of man's inquiries respecting himself especially, illustrating and establishing.

The transaction of the tower of Babel is the practical rejection of this principle. A portion of the descendants of Noah, in their journeys through Mesopotamia, lose their confidence in the promise which was the bond of their connection with an unseen Lord, fall into a slavish dread of the powers of nature, and attempt to provide against the evils with which these powers threaten them by brick walls. The result is a dissolution of society, indicated by the loss of that which is the great bond of human fellowship—communion of language.

This event has always been connected with the establishment of that Babel or Babylonian monarchy which is spoken of throughout the Scriptures as one, under all its changes of dynasty, because it preserved the same identical features, because it was originally established and continued to rest upon that principle against which the Jewish nation was the abiding witness. The disbelief of a fatherly government; the acknowledgment of power and not righteousness, as the idea of Godhead; the consequent worship of the powers of nature; the reverence for mere power in man;—these are the characteristics of that system, of which the building of the tower of Babel was at once the commencing act, and the permanent symbol. Under such a system of tyranny and superstition, language in its proper sense does not exist; words are merely the utterances of animal necessities, no bonds of feeling or society; nor, without that Divine interference which is recorded in the next passage of the book of Genesis, have we reason to suppose that man would long have had any instrument for expressing even those wants which are common to him with the brutes; far less that he would ever have found any method of communicating his deeper

wants, or that he would ever have been conscious of them. This interference is the commencement of Hebrew history, and, in one sense, of the moral and metaphysical history of mankind.

Moral and
Metaphy-
sical Phi-
losophy.

Family Period of Hebrew History, from B. c. 1921 to B. c. 1706.

A descendant of Shem, born in that country in which the foundations of the Babel monarchy had been laid, is awakened, the historian tells us, to a consciousness of his relation to an invisible Lord. The same Being who makes him aware of this mysterious connection inspires him also with confidence in his promise and protection.

Grounds of
relative
morality,
how first
apprehend-
ed by the
Jews.

The feeling of his own relationship to this Being is accompanied by a sense of the subjection of nature to Him. He has power to bestow the soil of the earth on whom he will,—it pleases Him to bestow a portion of it upon Abram. But the feeling of being a favoured man, though strong, is not the strongest in the mind of this lonely shepherd; far deeper is the feeling that he is a man,—in him all the families of the earth are to be blessed. This feeling is not one of a vague benevolence; it is connected with the thought of a distant posterity, over which he feels that the same Being who cares for him will preside; in whose fate he feels that he is and shall be interested. These truths, thus simply revealed to his heart, become the foundation of his life, and the key to the system of practical education to which he is submitted. Every outward event of his life, however trifling, is used by his Divine instructor to bring him into the consciousness of some principle. He goes down into Egypt with his wife, tells a lie for her protection, and finds that it has nearly proved her ruin. A separation takes place between him and one of his kindred, who is intended to be the founder of another race; it is made the means of kindling in him a fresh assurance of the distinct and glorious office which is destined for his seed. Again, he is brought into a wider sphere; a predatory war breaks out among some of the Canaanitish nations, in which his nephew is taken captive; he acquires a sense of the power which man possesses who is not a slave of outward accident and appearances, but is depending on an unseen Protector; an assurance that strength does not lie in multitudes; a new apprehension of the importance of his own position among the selfish and slavish people of Canaan. Yet he is not allowed to form an exaggerated notion of his own dignity. He is not alone in his worship of God; nor is the dignity, which he feels belongs to him as the destined head of a nation, the highest that God bestows on man. As he returns from the fight, he is met by a mysterious personage, who blesses him in the name of the Lord of heaven and earth; assumes to be his priest, and in that character receives gifts from the father of the faithful.

Hitherto this man has been brought into a lively sense of his connection with an unseen Lord, and of the favourable regard of that Being. This was the first part of his discipline. It was the ground of his practical relations to his fellow-men. It enabled him to be an honest shepherd, an affectionate kinsman, a good neighbour, a brave warrior, a humble and reverend man. But now began a second stage of his education, in which he was to be brought by the same practical method into the perception of deeper truths. A numerous seed had been promised him, yet he has no

Moral and
Metaphy-
sical Phi-
losophy.

son, not even the hope, or the apparent possibility of one; yet the Divine promises have in other respects been fulfilled to him; he is the possessor of numerous flocks and herds. The question, who shall be the heir of these, arises within him; he is told that a son of his own shall inherit them; he believes, and his faith is counted unto him for righteousness. Then, first the idea of a righteous Being, of One who must be true, however appearances and possibilities seem to be at variance with His word, is fully and practically presented to the mind and heart of Abram. He believes in this Being, and rises into a participation of his character,—feels that he is righteous, because the Being in whom he trusts is righteous. On this truth the moral life of the patriarch stands; on this truth the nation of which he is the destined founder is to be built. A vision of the future condition of his descendants, of their bondage, and of their deliverance, is the reward of his faith; and the mysterious sacrifice which accompanies it prepares him for the future discovery of another important element of national life. From this time the perception of a law or order which man cannot transgress with impunity, is more and more brought out in the mind of Abram, while the former acknowledgment of a merciful Protector is wonderfully interwoven with this new faith. The quarrels of his wife with the concubine she had given him, lead him into a clearer understanding of the nature of family relationships; yet he sees that the innocent woman is not forgotten by his Lord, and that her posterity, though not the heirs of the blessing promised to him, are still cared for. And now the habit of moral distinction, which had been beginning to be cultivated in him, was further strengthened by an institution which connected together his family life with his relation to God, and both with the prospect of a race to come out of his loins. The institution of circumcision is witness of the Divine covenant with Abraham and his race; the everlasting sign of a distinction between man and that which belongs to man; between man living according to that which is below himself, or man looking to that which is above himself; between man in union with God, and man separated from Him. The mere sign was permitted, nay intended to be diffused over many nations, partly as a witness that the *fact* was true of all, though the knowledge of the fact, and its practical consequences, belonged only to one, partly as a proof that it was the sign of a covenant and not a charm, and that, except in connection with the idea of that covenant, it was unmeaning.

As soon as the patriarch had been made conscious of his own spiritual position as a man, a remarkable vision to him in the plain of Mamre leads him into another and higher step in his education. He learns that the Divine Being is not merely his protector who gives him flocks and herds, and has promised him greater things than these, but that he has in him the capacity for fellowship with this Being: he learns at the same time that only by an act of condescension on the part of God can he be raised to enjoy this fellowship. If we consider the total effect of that vision on the mind of the simple shepherd of Mesopotamia, we shall see now, by the simplest method, the three feelings of the reality of God; of his connection and sympathy with man, and of an awful mystery which made it impossible to apply the rules and standards of number and time to Him, were gradually brought out, and how at the moment,

when the trust, and gratitude, and awe, the sense of fellowship, and the sense of distance, had reached their highest meeting-point, the announcement of the intended judgment upon Sodom concentrated them all in adoration of a righteous Being; yet how that very adoration called forth all the human sympathies of Abraham, and gave birth to the most confident, and humble, and awful intercession. The grand idea of retribution was one which the mind of the patriarch was now able to receive. All the meaning of righteous punishment without caprice, punishment in order to support order, punishment for the preservation of the universe—certain, discriminating, merciful, now dawned upon his mind, and became a part of its substance.

This is properly the moral stage of the education of Abraham. The third and concluding one is indicated by the long-expected birth of one who should be heir of the promises.

Both the former parts of his discipline, that which had instructed him in his relation to a Divine Being, and that which had brought him into some perception of His character, were necessary before he could fully understand his own position—could feel that, as a man, he was destined to exhibit the image of those relationships and of that character in his own life. He could now estimate the dignity of the parental office; could feel that a birth is the most solemn of all events; could understand how confidence in a Being above ourselves is essential to the right performing of every social duty; he could understand also how all the powers and energies of life must be referred to the same Being, and lastly, that these principles were the foundations of the state of which he was to be the head.

As soon as Isaac is born, the son of the concubine is cast forth, to be hereafter the head of a race, retaining much of the patriarchal character, and yet formally contrasted with the Jewish commonwealth. The members of it feel themselves brothers, fathers, husbands, and so far they carry about the blessings of circumcision with them. They are not merely given up to brute nature, but that grand feeling of being *persons*, of being distinct from their *nature*, of being united to a Being above themselves, has not dawned upon them, and without this men must continue in hordes, and can never enter into organized society.

This is the first offshoot from the Abrahamic stock, and is distinguished by many important characteristics from any of those tribes which existed previously to the call of the patriarch.*

As the Hebrew family becomes more and more distinct from these branches of it, the moral idea upon which it rests becomes more and more evident, and Abraham himself is initiated into higher and deeper principles. The last and grandest point of his education is that respecting the meaning and nature of sacrifice. We do not mean that he had not yet performed sacrifices, or that the act had not (as in the case of the solemn transaction, when he was informed of the destinies of his descendants) been invested with a great moral significance; what we mean is, that the *principle* of sacrifice had not yet been expounded to him by some

* It must not be forgotten, however, that the Moabites and Ammonites, the descendants of Lot, are never confounded with the other nations, but are described throughout Scripture as having some moral features in common with those of the Jews, and on that very account as more capable of being contrasted with them.

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

great practical lesson; it was indeed evidently reserved as the climax of his education; that without which it would not have been complete, and which in its turn must be interpreted by the previous steps of his discipline. The Being who had inspired him with such confidence in Him as his personal protector, and as the faithful and righteous Being, calls upon him to take the child of promise and to sacrifice him upon a hill many days' journey from his tent. To decide whether this suggestion was from a good or an evil source may have been difficult, or even impossible to the mind of the patriarch, in spite of all his previous training, but of this he felt certain, that absolute submission was due to that Being whom he served. And the absolute confidence which he reposed in Him, made him feel that he would not be suffered to obey any wrong impulse, and that the reason why the thought had been presented to him would, in due time, make itself manifest. He goes, therefore, as directed, simply and ignorantly confiding in the wisdom and goodness of the Being from whom he had received this child, to whom he had committed himself, and who, he believed, had mighty destinies in store for them both. The child-like submission receives its reward, his son is spared, and a new light is shed into his mind respecting his own character and relations, and respecting the God whom he worships.

The mighty mystery of a sacrifice of the will, as that which the perfect and Divine will requires of us; of the fruit of that sacrifice being the highest of all blessings, perfect sympathy between the creature and his Lord; lastly, the dim apprehension which after ages were to interpret, of the truth, that He who requires the sacrifice himself sets the example of it; that in this, as in all things, man is only his image:—these were the blessings with which Abraham was blest, and which he was permitted to transmit to his posterity, to be incorporated into their institutions, to become a part of their daily life, to preserve them from the abomination of human sacrifices, and to open their minds gradually to the apprehension of the great voluntary sacrifice.

Here the moral education of Abraham may be said to be completed, though the two remaining transactions recorded of him exhibit him as a witness for some great principles of moral order,—reverence for the dead, fidelity in transactions with men of a different race and faith, and the sanctity of marriage. We think it must be allowed that the simplest and most literal view of this history gives it an immense importance in the eyes of the moral historian; if we reflect ever so carelessly upon the ideas which it has developed, we must see that they have been those upon which the life of man and the life of society has turned. If we reflect ever so little upon the method by which those ideas became a part of the patriarch's mind, we shall see how wonderfully it connects together the ordinary blessings and transactions of life with his highest speculations; if we reflect ever so little on the moral effect of these discoveries, we must see that they tend to form a real manly character, and to make each man a true servant of his fellow-man. What is most remarkable in the history is, the absence of all glaring incidents, all oriental extravagance; the facts of the patriarch's life are ordinary facts, with nothing heroic or portentous about them, all their value lies in their significance; the events are only striking from the principles which they involve.

The history of the remaining patriarchs is interesting

and intelligible upon precisely the same grounds as that of Abraham. They are another chapter in the family records of the world; another step in man's education, by means of ordinary relations and every-day facts, and their own follies and dangers; into a perception of their relation to an invisible and permanent Being; into a knowledge of the social order in which He has placed them, and into contentment with this will and submission to that order. Throughout, the principle of faith or confidence in an unseen Being, grounded henceforth upon His express covenant with the Abrahamic family, is marked out as the basis of their family life. Those who possessed this had the grand element of humanity, that which raises man above sensual and brutish instincts; those who wanted it, became, in the main, the slaves of those instincts; though noble and generous feelings, the indications that they had a right to a better state than any to which they aspired, dawned through their ignorance and degradation. On the other hand, a disposition to craft and dishonesty beset those who felt that they had a higher wisdom and perceptions unshared by the men around them. The first are left to accomplish their wishes and work out the principle of self-will by becoming powerful men and founders of societies. The latter are trained by a severe and humbling discipline into a feeling of the reasonableness of their faith, and its inconsistency with all trick and deception. As the circle of relationships becomes larger, other truths are brought out in the same practical method; the mischiefs of polygamy, the conditions under which primogeniture is sacred, and on which it may for a higher end be superseded; the distinction between those who, retaining the sign of the covenant and remaining heirs of its privileges, mistook their position and sought for a selfish dignity; and those who understood that their great glory was to be heirs of a blessing intended for mankind, and to be witnesses for the God of Abraham.

It must often have excited the surprise, and perhaps the contempt, of the ordinary annalist, that the story of Joseph and his brethren, the favourite of peasants and children, should occupy a larger space in the records of the world's early history than all the politics of the Pharaohs and of Egypt. The historian of philosophy, on the contrary, feels that this family narrative develops principles which are really more important to mankind, and especially more important in records of the family age of the world, than the most minute chronological narrative of the dynasties and revolutions of Egypt could have been. But at the same time he will be far from admitting that the few facts contained in the book of Genesis respecting the condition of Egypt, and the influence exercised over it by a young Hebrew slave, are not in a political point of view of the highest worth. They reveal some most interesting truths respecting the progress of society, and the influence of moral wisdom and insight upon the institutions and destinies of a nation.

In the history of Joseph we see facts that are indeed most wonderful, but yet none which, in the ordinary sense of the word, are portentous. They are most strictly supernatural events, events indicating a supernatural Author, but they are events which rather exhibit the moral system and order of the world, than any departure from it. The feud with which the adventures of the youth begin, his purchase by the Ishmaelitic merchants, (the carriers of spices from Arabia to Egypt,) his rise in the house of Potiphar, the circumstances of

sical Phi-
losophy.

his disgrace and imprisonment, if more romantic than the facts in the lives of the simple shepherds of Palestine, are in nowise strange or incredible events. It is still the principle contained in them, the exhibition of inward and spiritual wisdom, triumphing over accidents, with the constant witness borne by them to those eternal truths which the education of Abraham had developed, that has made them so precious to all countries and ages. The facts which follow, understood simply and literally, have the same, and a still higher value. Nothing would be, *à priori*, more likely, and yet there is no fact which we are more glad to know from positive testimony, than that dreams were one of the means by which the minds of men, not possessed of an actual revelation, were awakened to the consciousness of spiritual faculties and to the existence of a spiritual world; they have that effect upon the peasant of our own day. However much they may have been used as instruments of superstition, men would be far more superstitious, because more sensual, without them. Again, the dignified position which the young heir of the covenant assumes, his calm assertion of a knowledge which those around him did not possess, yet the utter absence of all pretension in that assertion; his feeling that he is a witness for the God of Abraham, and that this God is the God of the whole earth, and watches over the welfare of all people, and reveals himself to those who are not within the scope of His covenant; in one word, the sense of a high vocation, and of that vocation being for the good of mankind, is the most striking and beautiful testimony that can be imagined to the effects of this Hebrew revelation in cultivating and expanding the heart and faculties of man.

Not the least memorable passage in the history is that which exhibits the Hebrew youth as educating the King of Egypt to habits of reflection and foresight, teaching him by a simple method to understand that there is a Divine order and system in the world, and that the providence of God is the ground of providence in man. This elementary lesson in political wisdom was a more effectual method of communicating moral and theological wisdom to the heart of Pharaoh than any direct indoctrination; and it explains how that method which we have observed in the Divine teaching of the chosen family became the model for all those instructions which they imparted to mankind, and which were pledges of the fulfilment of the promise, that in them all the families of the earth should be blessed.

Egypt.
Influence of
these first
moral ap-
prehensions
on political
institu-
tions.

In that version of the story of Prometheus, which Æschylus has made immortal: Io, the human animal who had been admitted to a fatal commerce with the Divinity, after many a weary journey through Scythian deserts, persecuted by the gadfly, and unable to escape from the pipe of the shepherd Argas, is told by the great patron and benefactor of mankind that in Egypt she shall bring forth a son to Jupiter. But he declares that twelve more generations shall pass away before the child is born, who shall restore form and repose to the degraded wanderer, and deliver the tortured prophet from his rock.

We can find no explanation of this mythus so rational as that which supposes the foundation of civil society in Greece, (attributed to Hercules,) as a corresponding

and countervailing power to the dead laws of nature, (impersonated in the tyrant Zeus,) to be that event which gives freedom to the long crushed spirit of foresight and wisdom, and rescues humanity from the restless and half-brutal condition of pastoral or nomadic society. According to this interpretation, the first part of the prophecy will of course intimate, that an imperfect attempt at political order, one not sufficient to give the energies and intelligencies of men their proper play, had been previously attempted in another country, and that this country was Egypt. We would not rest upon what may possibly be a mistaken view of this story, though it is strikingly confirmed by another version of it, given by the sophist Protagoras, in the dialogue of Plato, which bears his name, if there were not so many facts and traditions to show that it was the prevailing opinion in Greece. But how is this opinion consistent with the belief that the monarchies of Asia were the first in the world, a belief which sacred and profane history seem equally to support? the answer has been in part given already. These Asiatic monarchies began, according to the Scripture report of their origin, with rebellion against the first principles of moral order; they discarded the idea of fatherly government, trampled on the relations of family life, were connected with the worship of nature. Here was that true enthroning of Zeus, the mere lord of nature, in opposition to the Lord of man, which the Pythagorean poet perceived to be hinted at in the traditions of his country. The spirit of the earth, at once glorified and degraded by its union with the Lord, might be truly said to seek refuge from such tyrannies amidst hordes of wandering shepherds; and the spirit of wisdom and moral insight to be cast forth, incapable indeed of destruction, but conscious of subjection, bound and tormented.

It is quite possible then that moral culture and political order may have had their first birth in Egypt; and if this be once admitted, we believe it will be difficult to find a more intelligible account of that birth than the one which is contained in the simple narrative of Moses. The family of Abraham, as we have seen, was the formal witness against societies based upon mere combination, without reference to human relationships, and to a Divine father. A youth deeply imbued in the principles in which, through three generations, his family had been instructed by a Divine teacher, comes into Egypt in a period of approaching dearth. We need not suppose that the people at this time were mere barbarians; they had evidently traces of an older faith lingering among them, an appointed priesthood, who were the guardians of this faith, and (possibly) an hereditary monarchy. But we cannot believe that they had escaped the fate of all societies prematurely founded; or that the government of the Pharaohs was much less tyrannical, or their worship much less natural, than that which prevailed in Mesopotamia. By the providence of the Hebrew counsellor the monarch becomes possessed of stores, to which the people are compelled by their wants to resort. All their disposable property being exchanged for corn, they finally give up their lands; the race of independent proprietors ceases; Pharaoh becomes the general owner of Egypt. This revolution being thus quietly effected, Joseph is able to establish a system, resembling in its leading features the feudal system of modern Europe. This observation will only sound strange to those who have identified the accidents of that system with its essence, and have traced its origin to ideas of military

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

subordination. On the contrary, we affirm that family ideas were at the root of this system; the military part of it was only a graft upon a previous stock. In this sense we are bold to say that a feudal system is the cradle of all institutions. They may be strangled in their cradle; feudality may become all in all; and then a nation, in the proper sense of the word, will never be developed; but a nation must have some such commencement, or it will never acquire any healthy, vigorous life. The institutions of Joseph were not those which were intended for his own nation; they had had the discipline of a long family period, which had prepared them in the appointed hour to obtain, in the truest sense, an organized polity; but they were the only institutions which could have given rise to a moral and political order in Egypt: these must have been the features of Epaphus, if indeed he was born there.

We are by no means anxious to disprove those hypotheses respecting the migrations of priests across the land, or down the rivers, in which some modern mythologists delight—*Valeant quantum valebunt*; but since they leave one portion of the problem which they profess to solve untouched; since they explain merely whence certain notions may have been derived, not in the least how they became a part of the national mind, and as this is the question in which the moral and metaphysical student is interested, we do not see why the profoundest respect for the inventors of these theories should prevent us from believing a story transmitted to us on sufficient authority, and perfectly consistent with itself, which does extricate us from this embarrassment.

It should not be forgotten that views, however learned or interesting, of the manners, the government, or the literature of a people, or of an age, do not really satisfy the mind, unless they teach us how each bore upon the other; how each, in fact, involved the other. Even the exquisite chapter in Mr. Thirlwall's *History of Greece* upon the heroic age seems to us, we confess, to prove that the greatest ability, diligence, and command of resources are not sufficient to create a complete and living picture when the facts of it are distributed according to a formal and artificial method. The history of Joseph gives us very little help in understanding the details of Egyptian art, or worship, or policy, but we think that, by a few very simple touches, it supplies exactly those hints which we need to give order and coherency to facts with which every body is acquainted, but which probably dwell very loosely and confusedly in our minds. Taking the history of Joseph's adventures, of the influence which he acquired over Pharaoh, of the order which he established, of the descent of the Abrahamic family into Egypt, as we find them recorded in the book of Genesis, we can explain with tolerable clearness the position and circumstances of that people, the degree of cultivation which it was possible for them to reach, and the steps of their moral and political degeneracy.

The people constituting one large family, of which the king is the superintending father, and the priests the appointed instructors, acquire the notion of a fatherly government, which is strengthened by intercourse with the singular race which had been admitted to occupy a portion of their land; partly by positive traditions respecting their own education which the members of that race communicate, much more by the silent witness which is borne to this principle by the very existence of families so connected and upheld. The sense of a

superiority to nature which accompanies the cultivation of human relationships gives the first impulse to thought and intelligence among the people; and that intelligence is exercised, as it would of course be, in reference to their peculiar occupations—in discovering the arts of which an agricultural people are in need. There is no occasion to resort to the fantastic notions which the national vanity of Josephus has invented, and to suppose that the children of Abraham taught astronomy and geology to the Egyptians. They did what was much more valuable, they led them into that position in which men are able to seek out for themselves, at least that portion of knowledge which raises them above mere savage dependence upon chance supplies of daily food; enables them to sow lands in expectation of an harvest; to feel that there is an order in the world; to consider the past, and to look forward to the future. The priests, as we have said, would necessarily be the depositories of this knowledge, because it is a knowledge which only becomes possible when truths relating to the connection of man with his Maker, and consequently his superiority to the world around him, have been diffused in a country.

An agricultural people who have reached this point of civilization were not incapable of any of the conceptions which tradition leads us to ascribe to the early Egyptians. A perception of beauty implies a much greater moral and political progress; when the wonder inspired by the objects of outward nature is modified by a still higher admiration of the human form as the seat of intelligence or affection. But mere massive architecture seems to be especially connected with those first astronomical observations, which are awakened in the minds of a people devoted to tillage. The contrast between the simplicity of their daily occupations, and the grandeur of those objects which seem to regulate them, favours the development of that habit of mind which has created obelisks and pyramids. A notion of utility is connected more or less closely with all these buildings; but it cannot be said to be the motive of their erection. The religious feeling, the sense of awe and worship, which, as we have shown, is excited before any agricultural or astronomical knowledge is possible, was no doubt the primary impulse; one, however, which would never have left such memorials of itself, unless the government and habits of the country had lost much of that patriarchal character which we have attributed to them. This alteration would be accompanied or preceded by another, which the experience of history enables us without difficulty to set down. How soon in a country so wonderfully fertile as Egypt the victory over nature is changed into a deeper subjection to nature, how soon the absence of a curse on the soil moves a curse to the tillers of it, we need not tell any moderately thoughtful student. One of the first and most natural indications of this degeneracy is the tendency to consider men in reference to the services which they perform, rather than according to a law of human relationship. Institutions, of which territorial divisions are the basis, take place of those of which family life is the basis. In an agricultural country thus corrupted, a system of castes becomes inevitable. Again, family life ceasing to be the groundwork of institutions, the worship loses its original character. We need not inquire how pure it may have been in its best estate. Possibly there may have been at all times a confused notion that each relation of the family had

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

some distinct divinity for its prototype; at all times there may have been among the Egyptians a reverence for brother, sister, and mother gods; perplexing and interfering with, though still terminating in, the acknowledgment of a Father. All we contend for is, that the idea of a being related to man will have preponderated in their worship over the idea of mere gods of nature, and that in proportion as they become sensualized, the latter feeling will have gained the ascendancy, that these family gods would have become hopelessly enshrined in those objects of sensible utility over which they were at first piously supposed to preside; that there will soon have been castes of gods corresponding to the castes among men; that at last the objects and the powers will have become identical, and that thus, though we will not presume to fix at what precise period animal worship became prevalent in Egypt, there was no abomination of that worship which would not in due time naturally and inevitably be invented. The priesthood, in the mean time, who should have been the great means of resisting this downward tendering of the national mind, are carried along with it, and retain their power by ministering to it.

The awful and mysterious ideas of an elder worship remain among them to impart greater significance and fearfulness to the objects which that worship had once taught them to rule. The reverence for the priesthood is upheld no longer by their being the guides of the people to a wisdom which lifts them above themselves, and above nature, but by the notion that they possess some means of making the powers of nature hostile or propitious to them. It was the inevitable accompaniment of these changes, that the king, from the father of a set of families which composed the nation, should become the head of its castes. Still he would not be a despot in the Asiatic sense of the word; a feeling of his connection with the people over whom he ruled, that he was, as his taste or disposition might prompt him, the first warrior, or soothsayer, or handicraftsman of his land, would widely distinguish him from those rulers of the East, who looked upon their subjects merely as instruments of personal lust or ambition. Such rulers as were the Pharaohs would not indeed improve the cultivation of their people, but all skill and genius that were in the country they would call forth and employ. What were the limits of cultivation compatible with its moral and political condition we have considered already, and we may add, that the moral degradation of Egypt, though it retarded the progress of that cultivation, and reduced the body of the people nearly to the condition of brutes, may yet very well have permitted the continuance, even through many ages, of that degree of knowledge and art, which are expressed in its existing remains; in that portion of them, we mean, which cannot be proved to be the work of a period when the Greeks had far more than repaid to Egypt all that they are alleged to have borrowed from her. We reserve any remarks which we may have to make on the indications furnished by pictorial writing, of national progress in intellect, till we come to speak of the introduction of ordinary letters, a subject which will very soon engage our attention.

It is a question of very little importance whether the king who knew not Joseph was an invader or usurper, and of a different tribe from the monarchs who had preceded him. At all events it is probable that the thought, so natural to a monarch of some rude sagacity or cunning,

of enslaving or extirpating a singular race, dwelling in the heart of his country, and possessing inextinguishable privileges, was connected with other revolutionary schemes, for which, however, the minds of the people had been long preparing. The abolition of the institutions of Joseph, the complete substitution of a *caste* system for a feudal system, were probably the great achievements of his policy. He may have been a popular, as he was no doubt a magnificent monarch; originating, perhaps, or prosecuting with more vigour than any of his predecessors, the works for which Egypt has been, and will be for ever remembered. But it was he, and such as he, who caused Egypt to be without a history, to drag on weary ages of existence, in which the chronologist vainly attempts by unwearying diligence to detect a few uncertain landmarks. In destroying the family institutions of his country, he destroyed the seeds of its moral life, which might have sprung up and brought forth fruit in a healthy vigorous national society. He converted the priests into observers and contrivers of portents to answer the purposes of the politician; the politician into a mere plotter how to make a set of human machines work to the greatest advantage; and the people into mere slaves and brutes. He gave full sway to all those natural influences which are continually degrading the heart and spirit of man, till night and darkness become the only symbols by which the condition of Egypt could be adequately represented.

LEGAL PERIOD.

FROM B. C. 1491 TO B. C. 1271.

The Jewish historian is silent respecting the condition of his own people during the years of their sojourn in Egypt. There is enough, however, in his future narrative to warrant the opinion, which we might have formed without his authority, that they sank with the nation which their ancestor had been the means of raising. It would have been a violation of the design of their great Teacher, that they should have been more than a collection of families. They could communicate to another race the first principles of political order, because those principles are involved in the relationships for which they were the appointed witnesses. But these principles were not intended in their own race to generate institutions till the foundation of them had been laid in a more august revelation than any with which they had yet been favoured.

In this period then, previous to the commencement of their slavery, we may presume that they fell almost into the condition of an Arab horde; preserving, no doubt, accurate genealogies, the sign of their covenant, and in some families traditions of the knowledge and of the promises which had been imparted to their ancestors; but gradually losing their faith, and sinking, by the same steps as the Egyptians around them, into animal and natural worship. If we suppose them to have taken any interest in the speculations of the Egyptians respecting the arts of life, and the motions of the stars, we might have another way of accounting for their loss of patriarchal simplicity, and of that moral wisdom for which it was the great guarantee. But it is more consistent with reason and analogy to consider them as mere herdsmen, separated by customs and traditions from the people among whom they dwelt, acquiring only those notions and habits which insensibly pervade

the minds of all men, where there is no strong influence to counteract them, and daily exhibiting more of that sensuality and division, the growth of which among the sons of Jacob is so accurately traced by their honest historian. We know that this people did become an orderly national society. If we could obtain an accurate record of their passage into it, we might expect to find a key to many questions which will hereafter occupy our attention. Such a record should illustrate the law of national life; its connection with those relationships in which it has its birth; the distinct ground upon which it rests; how it is connected with morality; how it affects intellectual culture; how it promotes or retards the establishment of those wider relations which exist between men as the members of one race. The Scripture history, if it fulfil the purpose at which it seemed to be aiming in its account of the patriarchal family, ought to give us the hint of these discoveries, and to endure the test of its principles being applied to the exposition of puzzles which present themselves concerning the political and moral position of men generally.

This assistance, we believe, it will be willing to render; this test, we think, it will not decline.

The vulgar fancy of Josephus has crowded the history of the deliverer and legislator of his country with events, in which no person, who really feels the importance of the work which that hero performed, can compel himself to take the slightest interest. What can it signify whether or no he was the general of Pharaoh in his wars against the Ethiopians? or who could for a moment feel that the dreary pages which record his exploits have told him as much of the character of the man as the few simple words which describe his first feelings respecting the bondage of his country; his first consciousness of a vocation to be their deliverer; his efforts of rude and inconsiderate patriotism; his cruel disappointment at the discovery that the slaves whom he hoped to rescue from outward tyranny wore their chains upon their hearts? Or what narrative of his transactions after his exile in the land of Midian could teach us so well as his own clear and beautiful outline, the course which his thoughts must have taken, while for forty years he was tending his flocks in the deserts of a strange land? In that silence and solitude the traditions of his country would rise up before him in a new and startling shape. Hitherto they would have been connected with thoughts of the wonderful honour put upon his ancestors, of the degradation of their descendants, of the hope which still hung over their destinies. Now he would be led to connect these manifestations of an invisible Being with strange questionings respecting *himself*. The feeling that, as a Hebrew, he had some relation to the God of Abraham, of Isaac, and of Jacob; the feeling that such an hereditary, and as it were vicarious connection, was not sufficient to uphold one whose countrymen had lost all feelings of fellowship and kindred with their ancestors, and who was himself cut off from those countrymen, would force itself upon his heart, and would awaken in him the most awful of all human anxieties. "I am a distinct solitary person; I have a being of my own; of this being, no time, or accident, or circumstance can deprive me; this being no relations to my fellow-creatures can comprehend." With these thoughts would come obscure dreams of a higher relation perceived, not realized; a longing for the simplicity of those early fathers, of

whom he had been told, who walked daily in the cheerful sense of friendship with an unseen Being, without any of the restless strivings from which he was suffering. In his mind, the thought of a presiding, and ever watchful Parent, upholding his children in their path, directing them whither they should go, giving them promises, increasing their flocks and herds, and still more wonderfully allowing them to beget children in their own image, were mixed with perplexing notions of natural gods—the powers of the world, superintending the different creatures that minister to man; providing him possibly with the means of sustenance; unrelated and indifferent to the man himself. To harmonize these conflicting feelings would be impossible; his heart sighed after and secretly acknowledged such a God as his father worshipped, but his understanding led him to a very different conception; and the awe of his mind seemed to require some mere absolute Being, a Lord of man, not one who merely cared for him and provided for his wants. Of such a Being, the very contradictions in his heart seemed to speak. What was this sense of wrong, of solitude within him, but the intimation that there was such a Being, that there was a right, and a righteousness? At this anxious stage of thought he would recur again to his reflections and the bonds which connected him with his countrymen. The same conscience which recognised a superior judge, recognised his relation to other men; reminded him of acts inconsistent with his position towards them. There was a mysterious connection between these thoughts; where was it? what was the meaning and ground of it? A hope would begin to dawn through his miserable self-questionings; perhaps there might be one answer to them all; perhaps it might be vouchsafed to him; perhaps he might yet be the destined deliverer of his nation. This hope would assume a softer and quieter character, and yet not be quelled, when, after tending his flocks all day, he looked upon his wife and children, and saw in them the very pledges of Divine protection, which his fathers had esteemed most precious. It would be deepened and solemnized when he returned to the back parts of the desert, and beheld again that awful scenery which had nourished, though it could not awaken, the thoughts within him. To all these thoughts, the necessary consecration of every man destined to do any great work for mankind, the awful revelation in the bush, at the sight of which, he took the shoes from off his feet, was an answer.

The dreadful name, "I am that I am," was that name which for forty weary years he had been seeking. Here was the declaration of an absolute Being, the ground of his own being. But the accompanying words, which declared that He who had this awful name was the God of Abraham, Isaac, and Jacob, that He remembered his covenant; that He was the enemy of oppression and wrong; that He was a deliverer, and was about to manifest himself in all these characters, was exactly that reconciling discovery which he had longed for. The absolute personal Being whom he needed to sustain that feeling of personal distinctness, otherwise intolerable, was not another from the Being whom his fathers had worshipped; was still the head of all human relationships. This was that Being of strict and absolute righteousness, whom in the sense of his own evil he had felt to be so dreadful, and yet desired to know; in knowing whom he felt that he was evil no longer; for he rejoiced in His good, sympathized in

His good, and desired to see it prevail over all that resisted it in others and in himself.

Here was the deliverance from all those natural, sensual notions, into which the member of a degraded race, even if he had not been learned in all the wisdom of the Egyptians, must necessarily have fallen. The absolute Being was not a natural being; not removed from man, as a star is removed from man, by a hopeless absence of sympathy, but the perfect archetype of that righteousness which man perceives, recognises, and may exhibit in his own acts. "And these truths," the patriot would exclaim, "do not belong merely to me, though revealed to me; they belong to my nation; they shall be practically manifested in its deliverance from bondage; manifested through us to the whole universe."

On the basis of this revelation the Jewish polity stood. The idea of an absolute Being was the first principle of it; the idea that He was a righteous Being, the enemy of oppression and evil, the second; and these views were changed into practical realities by a third principle,—that this Being was the God of their fathers, that He had selected them from all the nations of the earth to be His witnesses, that He was the upholder of their family life. How these principles were expressed in their constitution, how they permeated every part of the system, our readers will understand just in proportion as they are attentive students of the books in which the nature of these institutions is declared, and of those in which their practical working is exhibited. We neither contend for nor against the notion which Michaelis and others have so ingeniously elaborated, that each law, and custom, and institution of the Jews had some reference to their position as an Oriental nation. In proportion as we believe the system to have been a wise one, grounded on deep principles, and constructed by a Divine architect, we must be inclined to believe that there was a skilful provision for the circumstances of the particular people to whom it was given, which of course would include the geographical position, the climate of their country, and their relation to the people around them. As little are we inclined to enter into the controversy between our learned countryman Spencer and the Dutch divines, whether any portion of these institutions may have been adopted and purified from some previously existing in the nation to which the Hebrews had been in bondage. If our view of the character of Joseph's instructions be a correct one, it will readily be admitted that they were *seeds* of institutions, not in the strict sense of the word institutions themselves, and that they would have given birth to various laws, customs, and systems, mixed of course with mythological notions, which for the very sake of removing those notions from the minds of his people the Divine legislator may have presented in their true and uncorrupted form in his own economy. There is nothing, we say, at all impossible or improbable in either of these speculations; the only complaint which the historian of philosophy is inclined to make against them is, that they have rather tended to obscure the groundwork of the Mosaic institutions, and to leave on men's minds the impression, that it requires little investigation in comparison with those subtle arrangements which concerned the outward life of the Jewish nation; or those which were to restrain them from the adoption of certain evil customs in the surrounding nations. A habit of looking rather at the

negative than at the positive parts of the Jewish system, its provisions rather than its principles, has prevailed to a great extent among our divines and biblical critics. The vague phrases that it was intended to provide against idolatry, and for the recognition of the Divine Unity, have hindered students from steadily examining these institutions, and considering what information they give us respecting the grounds of national and social life. Our conviction is, that there can be no clear understanding of the principles of political order, as they existed in Greece and Rome, and as they do exist in modern Europe, until the constitution of this Divine commonwealth is meditated upon in an honest and humble spirit.

Our limits will only permit us to notice just so many of its peculiarities, and of the facts which record its establishment, as are necessary to throw light upon the connection between the moral speculations and the social condition of man.

Passing by, therefore, the hint which is given in the very commencement of this narrative of the distinction between the priest and the lawgiver; passing over that series of remarkable signs by which the dominion of an unseen God of righteousness over the different powers of nature was established, the tendency to natural worship in the minds of the Egyptians condemned, and the legerdemain of their magicians confounded, events most important as asserting the principles on which the Jewish nation was to rest; passing by for the present even the last and most terrible of these signs, which bore most closely upon the ideas of primogeniture existing in the old world, we proceed to notice the three leading peculiarities of this system—the *TRIBE*, the *CODE*, the *TABERNACLE*.

The *tribe* system is the link between the family and the national life of the Hebrews. There were not a set of lares and penates presiding over the hearths and households of the Hebrews, and a Jupiter Capitolinus who ruled in the citadel; the God of their fathers was the God of their nation. There was no caste system, separating them according to their occupations; the distinctions were all genealogical; the land, when they possessed it, was to adapt itself to distinctions previously established, not to be the cause of any. The family life was bound up with the national by the festivals, most of all by that of the Passover, the celebration of a glorious common deliverance, to the sacrifice attending which every family contributed its quota. It was connected again with the institution and administration of the laws by the selection of a set of elders, the heads and representatives of the different tribes, to be the magistrates of the land. It was connected with the ecclesiastical body, in that one whole tribe was formally constituted the priesthood of the nation; that the priests succeeded by a law of hereditary succession, and were considered, in their devotion to the immediate service of the tabernacle, as substitutes for the first born of every family. By this means the idea of primogeniture was upheld, while there was a perpetual witness against the abuses to which it sometimes leads. The early history of the Jews had warned them, by the instances of Ishmael, Esau, and Reuben, that the principle of primogeniture, though grand and sacred, exists for certain moral ends, for the sake of which it may be sacrificed. The new institution reminding them what that moral end was, kept up the balance of feeling, the absence of which has in different nations by turns given a dangerously exclusive pre-

dominance to feudal notions, or expelled them altogether. These are a few hints respecting this side of the Jewish constitution, which our readers may find an interest in following out for themselves through all the details of it.

In doing so, we would entreat them never to lose sight of the great moral and metaphysical lesson which the harmony of their family and national life taught the Jews, and for the sake of which we have alluded to it here; namely, of the essential distinction, and the necessary union between relative and absolute morality. Into how many questions the neglect of this distinction, or the want of this union, has led men; how essential the practical recognition of it is to the theoretical apprehension of it; how this recognition is connected with political institutions and theological opinions, our subsequent history will abundantly testify.

The prescriptive Code of the Jews was not given them till the institutions of which we have been speaking had been formally established. They had recognised the God of their fathers as their deliverer, their protector, and their friend, before they were called upon by any solemn act to recognise Him as the I AM. Yet, as we have shown already, on this recognition national society depends; without it, there was no permanence for the family life which it protected. The same grand truth, which Moses needed to call forth in him the feeling of his own personality, and to prevent that sense from overwhelming him, was needed to give being to the Jewish nation. Family life exists in the feeling of connection and association; national life, in the feeling that each man is a distinct person.

After an awful preparation of three days, amidst thunders and lightnings, and the sight of a devouring flame, those words were proclaimed which every Jew felt were addressed to him; which withdrew him from relationships, friendships, sympathies, into the secret chamber of his own spirit, obliged him to feel that he was a distinct living person, obliged him to recognise something in himself as at war with an order, which he at the same moment confessed to be right. Yet along with the awakening of this dreadful sense of personality was a deeper and stronger feeling, that he was the member of a commonwealth, that every act which he or any other man did affected the commonwealth, that the protection to which he as a single person must look, was that which overshadowed the whole society. "I am the Lord thy God which brought thee out of Egypt," were the first words that every Hebrew heard from the holy mount, and which, before even the sense of evil had been awakened in him, reminded him that he personally shared in the blessings of his nation; assured him that he personally was observed and protected by the unseen head of it.

The history of the Jewish nation and of the world is a commentary on this code. Whatever causes have broken up commonwealths, or made society untenable, or turned men into brutes, are therein set forth and predicted. The loss of faith in an unseen protector and guardian, the idolatry of sense, the loss of reverence for the name which speaks of the reality and personality of Him whom we worship; the loss of an institution which teaches men to view Him as an object of fixed contemplation, the ultimate resting-place of the spirit, and not merely as ever acting for them, and which connects that instruction with the rest of all creatures from their labours, thus reminding them that, both in their

toils and in their repose, they are His image—loss of reverence for parents leading to incessant emigration; loss of reverence for life, for marriage, for property, for character; lastly, which is the source of all these, the grasping, self-seeking, money-getting spirit;—what more wonderful index can we possess to the history of the decline and fall of empires? The idea of this code necessarily excludes all prohibition of mere excess. It is an important part of the statutes of a nation, to provide against acts of excess, as occasion shows them to be detrimental to the community; but it would be a violation of all principles of order and distinction to introduce them into a system of universal prohibition. In the Jewish economy, there is a strict and admirable discrimination between the laws and the statutes of the nation, between the positive denunciations against fixed evil and the provision against emergencies and overt acts; between the rules which had reference to the actual condition of society in a particular nation and the principles which are the groundwork of society everywhere. But a still more important distinction is rigidly observed between the literal code and the righteousness which is the ground of the code; which can be contemplated only in the acts and life of a person; which is positive, not negative; which is attained through a knowledge of the character of the Being we worship. A recognition of his authority is implied in national order, the recognition of His righteousness is connected with a higher universal human order.

The third part of the Jewish economy has a reference to this higher righteousness and higher order, and recognises man as capable of holding communion with the unseen ruler of his nation. THE TABERNACLE was the grand witness and practical manifestation of this truth, involved alike in the family and national life of the Jews, the crowning glory of both; for which both existed. The first part of the Jewish system expressed the idea of fatherly care and government; the second, the idea of a righteous Being formally distinguishing between good and evil; the third portion, the idea of communion with this Being; the last idea including, though not superseding, both the others, and constantly reminding the Jews that the end of the Divine education and law was to exalt them to the contemplation and knowledge of himself. With this grand theological idea was connected, as we have already intimated, a great human principle. It was the universal side of the Jewish polity, it was the link which bound the particular nation to the human species, which enabled them to understand the promise made to Abraham, that in his seed all the nations of the earth should be blessed, which led him to regard his own separation as a means to an end, not an end in itself.

By keeping these observations in remembrance, we are able to understand the relation of the parts of the Jewish ecclesiastical system to each other, to the civil government, to the members of the nation, and to mankind; an inquiry more important than it may first appear to the study of the moral and metaphysical history of the Jews and of other nations. The system may be referred to these three heads: 1. the tabernacle itself; 2. the priests; 3. the sacrifices. The building which was prepared and set up with so many awful ceremonies, and which attended the Jews in all their wanderings through the wilderness, brought continually before them the idea of an awful and mysterious presence; not floating in the air, not diffused through the

Moral and

sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

forms of nature, but a real and personal Being, connected primarily with them; only, in the second place, with the rest of creation. While man was thus elevated in the scale of creatures, by feeling that the Maker of all things was his friend, the idea of absolute truth and righteousness presented in the law, seeming to crush his aspirations, really gave them a surer confidence and a higher aim. The possibility of becoming like this Being by contemplating Him; the hope kept alive by so many national promises of a more complete manifestation; the thought of a deep abyss of being, which man could never fathom, but on which he might repose; these thoughts, meditations, hopes, were kept alive by the presence and by the order of the mysterious tabernacle, and were communicated, as we shall see hereafter, through it, and through the more magnificent, permanent edifice which afterwards received the ark of the covenant, to the mind and heart of the Jewish prophet.

The *ministers* of this awful sanctuary were distinguished, though by no means separated, from the elders who represented its family constitution, from the chief who promulgated and interpreted its laws. The office of the whole body was distinguished by garments for glory and for beauty, betokening, as the words inscribed upon their foreheads implied, that they were a dedicated race, the witnesses to the whole nation of the fact of a connection between them and a perfect Being, even when they were not performing the duties by which that connection was expressed and realized. Yet they were in no sense separated, either from the nation corporately, or from its particular members. They represented the dignity, the purity, the glory of the nation, that which it really was, not what by forgetfulness of their privileges its members might become.

They took cognizance of the most practical wants and sufferings of the people; they were the divinely appointed physicians of the land, educating the suffering Jew to feel that his bodily health was watched over by a Divine guardian, to understand that disease itself is under a law, and that the knowledge of the law leads to the remedy. In the case of leprosy, higher truths were indicated, and a practical apprehension of them imparted to the people. Even disease was made a means of teaching them the lesson which the whole Jewish polity was devised to illustrate—that communion between men is grounded upon their common relation to an invisible Ruler, and that the impurity of one man may defile the whole congregation. Another branch of the priest's office also, that of defining the clean and unclean food, enabled them to act as the practical instructors of a rude and ignorant people. Without supposing any deeper reason for the prohibitions than that which Michaelis has assigned, and even being ready to admit that in some cases that reason will be difficult to discover, we contend that mere arbitrary appointments of this kind must have been most useful in cultivating habits of distinction in those who were subject to them, in making them feel that they were in the midst of an order, even when they were not able to interpret or reconcile the different portions of it.

But the grand vocation of the priest, that which really brought him into connection with all the members of the commonwealth, that which gave the meaning to all his other functions, was to offer *Sacrifices*; those daily sacrifices which each man brought to the door of the tabernacle; that more august annual sacrifice which the high priest, the Coryphæus of the body, offered on that

day when he went alone into the holiest of the holy. We have pointed out the idea of communion as that to which the tabernacle and the office of the priest alike pointed, which being absent, institutions become a dreary weight, law an intolerable oppression. To this idea we must refer sacrifices, or we have no clue to their meaning in the Divine commonwealth, or in those whose system we shall have hereafter to examine.

That the nation, and every member of it, is united to its Divine King and head, that as long as each member abides in the covenant, retains his allegiance to the head of the nation, and his fellowship with the other members of it, he enjoys this connection; that by every transgression of the law which defines his position in reference to his God, and to his brethren, he practically forfeits it; that something must be given up before the connection can be re-established: these are the elementary principles in the idea of sacrifices, as it is expounded to us in the Jewish Scriptures, and as it is illustrated even in the most corrupt practices of heathen nations. The question which we shall find at issue between them is this: Is the hinderance to this intercourse some capricious distaste in the mind of God towards the suppliant, or is it the impossibility of fellowship between two beings, in whom there exists a dissimilarity of feeling and character, and whose relation to each other has by some act on one or other side been disturbed? If the former notion subsist, the value of the offering would of course regulate the petitioner's chance of success. A hecatomb will be worth a hundred times as much as a single ox; a child or a beautiful woman, in countries where human creatures are revered, will often be thought a more hopeful offering than either. The other noble idea of sacrifice is that which is expressed in the Hebrew institutions. The Jew must not, dare not, fancy that a more costly offering than the appointed one will do him greater service. If he brought to the door of the tabernacle of the congregation some precious sacrifice, devised after his own conceit, and not according to the provisions of the law, the priest was bound to reject him, and to reprove him, or he virtually renounced his own office. Every thing in the matter and mode of the offering was rigidly prescribed; it was the *will* of the offerer only which the law permitted and required to be free. Thus the idea of an unchangeable Being lay at the groundwork of an institution which, in every other country, left on the mind the most lamentable sense of fluctuation and caprice. Thus he was taught to feel on the one hand that he was in a fixed relation to the King and Father of the nation, and yet that, as this King and Father was a moral Being, all the blessings of that relation are forfeited by an immoral state of mind. Thus he was taught by what kind of acts that immoral state was produced, and that relation violated; by acts, namely, of self-will, separating him from God and from his brethren. Thus he was taught what effect that self-will produces, how it enslaves a man to the animal nature, above which he had been raised, by being admitted into fellowship with his Creator. The animal which he offers, teaches him what it is that he has to sacrifice; the voluntary will which is required of him, teaches him what it is that has need to be restored; the priest, who alone can offer the sacrifice, teaches him that the connection between him and the invisible Being is upheld in the person of some mediator; and, together with the great act of atonement, prepares him for the idea of a

losophy.

Being who, by the offering of his own body and the entire sacrifice of his own will, shall be the bond to unite together the whole race with the perfect and absolute will. So wonderfully did the idea of moral order in the universe, of God, as the founder and upholder of that order, of man, as a rebel against that order, and yet capable, by a mysterious process, of being brought to apprehend it, evolve itself through institutions apparently the most purely national and exclusive.

We can but hint at a subject closely connected with sacrifices, that of purifications, as a part of this great system of education, and one which illustrates some of the most difficult passages in the moral and metaphysical history of mankind.

By following out the method we have been endeavouring to develop, and especially by keeping in mind the threefold principle of the Jewish commonwealth, answering to its patriarchal, legal, and ecclesiastical institutions, our readers will be able, without difficulty, to trace the connection between this or any other part of the scheme which we have left unnoticed, and its general design. It remains that we should say some words on the intellectual development of the Jewish nation, corresponding with these steps in its moral and social progress. Moses tells us, that the deliverance from Pharaoh was celebrated in a triumphal song. This is the first instance of Hebrew *poetry* in the Scripture; for if the prophecy of Jacob respecting his descendants be rhythmical, (a doubtful question,) that form must have been imparted to it by the historian, in order to preserve the connection which the mind of a Jew, and even of most pagans, recognised as so close between prophecy and poetry. This fact is worthy of our notice; for it is an observation which has been often made, but scarcely enough dwelt upon by those who have endeavoured to ascertain the meaning and functions of poetry, that it never existed apart from some definite form of political society, and that the periods in which the bonds of political union have been most strongly realized, are those in which poetry has manifested itself in its greatest power. To say that poetry has never coexisted with savage life, or with any condition of society in which the selfish feelings have predominated over the social, would be a trite common-place. But it is a great question whether any kind of social feeling except that to which we give the name of NATIONAL, does naturally express itself in this way. In the communion of mere family life, the soul is unconscious of its own workings; the man becomes, in the strictest sense of the word, *attached* to the members of his own circle, and forgets himself in them. A result not altogether dissimilar takes place in the universal communion of the church, which, when it is strongly realized, often absorbs the conscious faculties of a man altogether, in the contemplation of the Being who is the centre of it, or of the different members of it, whom he is to love even as himself. It is exactly in that communion between men, which exists in a political body circumscribed by definite limits, feeling itself in a certain sense at war with the rest of the world, that each man vividly and consciously realizes his relation to the whole, and rises through the sense of that relation to the dignity of a personal being; and of these feelings poetry seems to be the legitimate and intended expression. The crisis of deliverance is that which gives occasion to its first utterance; one person, who most strongly feels that he is a member of the nation, expresses by words the excited feeling of his own spirit, and those

words married to music are felt by the whole society as their own. That the first poetry would inevitably be song, that it will be a long time before it is even conceived possible to separate it from music, we need not tell any reader. The explanation of the fact we find in the connection of poetry with national life, and in those peculiar conditions of national life which we have been endeavouring in this chapter to set forth.

If we have been right in our remarks respecting the feelings which give birth to poetry, it will not be strange that it should be contemporaneous with the commencement of orderly and coherent *language*. After the formal notions of language have become parts of our habits of thought; after we have been used to separate altogether the beholder from that which he contemplates; objects from the feelings with which they are viewed, acts from their agents, qualities from that in which they inhere, it is delightful to find the connection restored to us in poetry; to find that we are in the midst of a living world; to see deeds performing by actual persons; dead names restored to life by being united with their attributes. Not that poetry leads to any confusion of these great distinctions, but rather enables us to realize them more vividly; and above all, that grand distinction between persons and things, which is half lost when we treat of both alike as mere subjects of narrative and speculation, is felt in its power when we find ourselves actually in the midst of our fellow-men, sympathizing with them, and especially rejoicing to see how they exercise a government over nature. From these considerations we may understand why poetry, which restores language when it has been corrupted, must also be almost identical with it, in its infancy, why the common notion may be no extravagant one, that the Greek language was created by the Homeric poems. Mr. Thirlwall has endeavoured to solve the difficulties respecting the introduction of LETTERS into Greece by supposing that they too may have been first employed in the poet's service. That written characters will appear very shortly after the language which they are to transmit from generation to generation has acquired a distinct order and formation, we cannot doubt. Both, we believe, accompany the commencement of a national period; but as there seems no reason why poems should not be preserved, for a time at least, by recitation, we do not see the need of letters for the sake of; but we do perceive the indispensable necessity of letters for the sake of that which is the most characteristic element of national life—its laws. We are thus led to adopt, in preference to Mr. Thirlwall's hypothesis, a much older and less ingenious one,—that written characters, as distinguished from that writing which is the imitation of natural objects, first come into use in every country where formal codes or charters are grafted upon its institutions and common law. By this observation our readers will see that we adopt as literal the declarations of Moses respecting the giving of the law, and the method of its preservation.

And it seems perfectly consistent with the whole idea of this economy, that the deliverance of men from the thralldom to nature and natural worship, the worst part of their Egyptian thralldom, and without which the other parts of it could never have existed, should have been accompanied by that introduction of letters, as well as of laws. Neither were necessary in the first patriarchal age. Then there was no explicit code; then heaps of stones were sufficient to establish contracts and preserve traditions. When this patriarchal system had given

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

birth to the feudal institutions of Egypt, the want of some other method of communicating the will of the sovereign or the dogmas of the priests would have been felt. Natural objects have still the dominion over the heart and mind. Language is not felt as an expression of human thought, but as a description of natural objects. The invention of a system of hieroglyphics is the natural result. It may have afterwards been appropriated to the service of the priest, and been invested with a mysterious dignity, when ordinary writing had been introduced from other countries; but it never can have been invented at a period after ordinary characters were in use. Nor can we conceive that the soul of the Israelite could ever have enjoyed that emancipation from the tyranny of sense which was intended for him when he was brought under the law of an invisible and personal Being, if he had not been taught that the words which were the utterance of his spirit were not dependent on the forms around him; that nature was the image of the thoughts which his words expressed, not they the image of nature; and if to sustain these all-important instructions he had not been provided with such means of formally distinguishing those words, as made the use of natural symbols unnecessary. Upon this observation we would ground another. Song, we have seen, was the first expression of the Jewish spirit after its deliverance from captivity. But the earliest records of the Jews are not, as in the case of the Greeks, poetical. Poetry belongs, in its highest form, and its most mature efforts, to the third stage of their history. The difference is very interesting, and is connected with the difference between the Hebrews and Greeks generally. The peculiar Divine education of the Hebrews, instead of superseding the regular progress of the human spirit, gave the most orderly direction to that progress. But the natural overflow of the human spirit in poetry, at the very infancy of its political existence, is not favourable, as Greek history will show us, to the consistency of society, or to the permanence of moral feeling. Unless law and history in a nation precede the continuous exercises of the poetical faculty, there is little hope that any fixed national order will control the struggle of the individual intellect and will. It was therefore most accordant with the Divine scheme, that the teaching of the nation, when that teaching for the first time took a literary form, should be through the means of a history, possessing indeed much of the charm of poetry, by its simplicity and clearness, but still formally distinguished from it, not merely by the absence of rhythm, but also by its strict chronological method, and the want of a central object.

The third step in the Hebrew intellectual development of this period is connected with their ecclesiastical life. Architecture here, as every where, had its source in the idea of communion with an invisible Being, and presented that idea outwardly. The account which is given of the fabrication of the tabernacle expresses with great clearness the principle of all these records: "See, I have called by name Bezaleel, the son of Uri, the son of Hur, of the tribe of Judah; and I have filled him with the Spirit of God, in wisdom and in understanding, and in knowledge, and in all manner of workmanship, to devise cunning works, to work in gold, and in silver, and in brass, and in cutting of stones, to set them, and in carving of timber, to work in all manner of workmanship. And I, behold, I have given, with him Aholiab, the son of Ahisamach, of the tribe of Dan; and in

the hearts of all that are wise hearted I have put wisdom, that they make all I have commanded thee." The revelation of certain great truths to the legislator of the people, the selection of a particular man to set forth those truths in sensible forms, which forms are intended as the means of educating the whole people into the perception of the truths;—this is exactly the order which the Scripture is uniformly presenting to us. The Lord of man unveils himself to the faith and wonder of a man whom he destines to be the moral guide and teacher of his people. But outward nature is the expression and mirror of those truths. Certain men here and there are endowed with the gift of perceiving the correspondence between nature and the mysteries in the heart of man; these are of a lower grade than the former in the moral scale, but still they have a glorious vocation. They also are the teachers of mankind, converting the very senses which are wont to be its tyrants into the means of its deliverance. We shall find hereafter how strikingly this view of the relations of men to each other in a state illustrates the doctrine of Plato on the same subject. We shall not here enter into any observations respecting the nature of Hebrew architecture; its contrast to the mere massive temples of Egypt, or to the graceful and definite temples of Greece. Such remarks, if we have leisure for them, will occur best when we notice the final achievement of the Jewish spirit in this direction, in the age of Solomon. We merely notice the subject at this period in order to show how the same Divine power which gave the Hebrews a polity, and made that polity a means of awakening them to a perception of the three great moral principles in which all society is based, tribe relations, positive law, communion with God, show forth their intellects, also, in three directions corresponding to these. First, in poetry and music, expressing their sense of common relationship, and giving form, and meaning, and harmony to language; next, in letters, arbitrary devices, in which man exults because they are arbitrary, determined by his will, not by nature, to convey the laws by which he is bound, and the thoughts which he utters from generation to generation; lastly, architecture, by which he compels nature itself to give him symbols which may represent the deepest speculations and principles of his mind.

Such is a very short view of the Divine education of the Jewish nation, at this most important crisis of its life. Our readers will not fail to perceive how it is connected with that earlier period of family education; nor, we think, while they contemplate the relation of one to the other, the gradual and wonderful growth of one out of the other, by processes so analogous to the subtlest and most mysterious processes of nature; finally, the integrity and coherency of the whole system; will they refrain from asking themselves whether the supposition, that the historian who records it was a fabulist, does not involve the belief of more portents and miracles than the most child-like acknowledgment of his veracity?

The nature of our work does not permit us to notice any further particulars respecting the history of the Jewish people during this period.

The journeys through the wilderness do indeed illustrate the deepest moral truths, and are most instructive, as an illustration of the experimental method by which the members of the chosen nation were educated, to understand the tendencies of their minds, the meaning of

losophy.

the law of God, and the purpose of his discipline, and when we come to study the history of the people at a later period, we shall find how the records of these journeys at once gave the impulse and supplied the materials to the reflections and meditations of their seers. Equally important is the history of their entrance into Canaan; of their victory over the slavish, degraded, natural people of the land, through the might of their confidence in an unseen, personal God, and the faithful records of their own degradation and misery, when they forgot to worship their deliverer and friend, and became the servants of their senses.

But these records are only the illustrations and working out of principles, of which we have already spoken, and therefore, though most important in a history of humanity, can hardly be said to belong to a history of philosophy.

*Interval between the Second and Third Hebrew Period.
The Phœnicians.*

The Phœ-
nicians.
Influence of
the appre-
hension of
positive
morality
imparted to
the He-
brews on
political in-
stitutions.

It is an opinion which was prevalent in former times, and has gained strength from some recent discoveries, that the Edomites had attained a remarkable civilization at the time when the Hebrews were bondsmen in Egypt.

Supposing there to be any sufficient evidence that the excavated buildings of Arabia Petraea were really the work of so early a period as this, they would be the symptoms of a people who had attained a very unnatural and precocious knowledge of the mechanical arts, unsustained by that moral cultivation which alone can make the history of a nation interesting, if it be not more correct to say, which alone can give it a history at all. The inferences which have been drawn from the book of Job respecting this people, are at best of a most doubtful character; for that book was at all events intended to be, and must be leavened with Hebrew wisdom. It may be intended as the history of a man who retains the old patriarchal faith without being a partaker of the blessing of the law and civil polity of the Jews, and if so, the scene of it would very appropriately be laid in the country of the descendants of Esau.

But before we found any conclusions upon it respecting their moral state, we must assume both the date of the book and the object of it, and then, contrary to all principle and analogy, must speak of it as an Edomite, instead of a Jewish work, and this too without attempting (as who dares attempt?) to exclude it from the canon of Scripture. At any rate, it would be inconsistent with our idea to recognise any nation as spiritually important which has not made its importance felt by exercising some direct influence on the character and condition of mankind.

There is, however, a most interesting question connected with this part of our subject. All traditions seem to prove that Phœnicia must have arisen into importance between the time in which the Jews invaded Palestine and the reign of David. How far may the formation of its civilization and power be traced to the influence of Jewish ideas? Is there any thing to warrant the supposition that the Jews, in their second or legal state, may have acted upon the conquered nations of Palestine, or upon their immediate neighbours, in any thing like the same manner that their fathers in the patriarchal stage appear to have acted upon the condition of Egypt? It falls distinctly within our purpose

to throw out some hints upon this subject, because it is connected with the influence of moral principles upon the order of society, and because it will remove many difficulties out of our way when we enter upon the study of Greek philosophy.

It is certain that the Greeks attributed a part of their own cultivation to Egypt, a part to Phœnicia. It is not necessary to inquire whether the stories respecting their early communication with either country be partly true or wholly fabulous. They prove at least this much, that the Greeks of later times discovered in a certain portion of their own national ideas so close a resemblance to those which they found embodied in the traditions of the priests of Thebes or Memphis, and in another portion of them so close a resemblance to those which were recognised by the merchants of Tyre, that they had plausible reasons for supposing them to be derived from those two sources respectively.

Now we think that some modern theories have considerably embarrassed the question, Which portion of the Greek feeling and mythology most corresponded to that of the agricultural, and which, to that of the trading people? It has been maintained that the two divinities of Phœnicia, Baal and Astarte, represented, one the productive and the other the passive powers of nature. So refined a notion as this, it seems to us, can never have been the foundation of any national worship; it is evidently a late philosophical exposition of a popular belief, which must have had a very different and a much more living root. We do not deny that there is a stage in society in which the worship of outward nature, in the strict sense of the word, becomes the characteristic of a people. We shall have to examine by and by such a stage, and to consider the meaning of its phenomena. We shall find them altogether different from those of Phœnicia, and we shall find that they assume a much more grand and startling shape than that of investigations and reflections respecting the productive and passive powers of things. Men do not get their notions of these from the outward world, but from themselves. Baal and Astarte we believe to have been neither more nor less than the Lord and Lady of Phœnicia, who might be worshipped in a hundred different natural forms, but the idea of whom was suggested, not by the sensible world, but by the forms of national life. Here then would be the great difference between the Egyptian and Phœnician. The one would worship family gods, fathers, mothers, brothers, sisters, husbands; the other would worship national gods, kings, queens, legislators, champions, heroes. The first worship, as we have shown, is connected with the cultivation of the soil, and gives birth to rude and massive forms of art; the second will be found in union with a commercial spirit, and with an approach to the more definite and precise architecture. The tendency of the former will be to mere grossness; of the other to mere sensuality. The intellectual degradation will be greater in the first, the moral degradation in the second. If these observations be correct, there can be little difficulty in determining which portion of the Greek character and mythology had a counterpart in Egypt, and which in Phœnicia; and we think that a careful examination of the legends respectively given to each country would lead to the same result with our own *à priori* speculations; we think that both would show, that whereas the ideas of family life, which existed in the Greek mind and were embodied in its forms of worship, would enable the travelled Greek to feel a

Moral and
Metaphy-
sical Phi-
losophy.

Moral and

sical Phi-
losophy.

sympathy with that early form of society of which he found traces in the African nation; his hero worship, his notions of art and letters, all that strictly belong to him as a political being, would very naturally, though, perhaps, quite falsely, have been supposed to be brought to him by the restless traders of Asia. Here then would seem to be the answer to our first question. We have explained the difference between the position of the Jews at this time and in the patriarchal ages. We have seen that while a permanence was given by institutions to all their early teaching, great moral principles hidden and implied in that teaching had been brought out into clear manifestation, and formed the ground of the Jewish national life. It was not merely in the father of the family that they beheld a type of their unseen guide and friend; in the legislator, in the priest, in the conquering leader, and finally in the judge, they had the witness of his presence and his power, the living type of his order and government. The last-named officer especially marks at once the stage at which the Hebrew nation had arrived, and the difference between them and all other people. He was the champion, the hero, who was raised up at some particular emergency to restore the fallen commonwealth; but his heroism was not his main characteristic; it never enabled him to become the founder of a dynasty, or even to exercise the kind of power which the able tyrants of the Greek colonies acquired in a later age. His name indicated that he was the representative and expounder of the law, that he recognised right and wrong as permanent distinctions, which it is the highest honour of the ruler of a state to perceive and enforce, which he never can create or set aside. This was the great and glorious distinction of the Hebrew—the lock of hair, with which when he parted he became weak as another man. While he retained it, he was the unconscious means of communicating to tribes, which had no participation in his higher privileges, notions of order and law, which raised them entirely out of the condition of savages, even where they did not issue in any high moral cultivation. Of such notions the Phœnician worship seems to have been the expression. Conceptions of a Divine judge and law-giver and king would dawn upon them through the forms of their old traditional religion; would incorporate themselves with its polytheism, and would give that polytheism a humanized character. As these ideas obtained greater power and prevalence, society would become organized, and would in its turn give to the moral conceptions more shape and definiteness. Civilization in the pupil would seem to proceed far more rapidly than in the master, for the sense of their own powers, which men acquire as soon as they feel themselves members of an organized community, would not be checked by the feeling of submission to a prescribed system and a pre-established law. They would arise speedily into the condition of a kingdom without any of that tedious preparation by which the Hebrews were taught to understand what a kingdom means. They would soon have their seaports, their fleets, and their colonies; in every country they would leave vestiges of themselves. They would expand the minds of those to whom they came with notions of distant worlds, of the power which man possesses over the elements, with a dim feeling of the dominion which mind is meant to possess over matter. And little will it have been suspected by those who received this lore, or those to whom they have transmitted it, that all this feeling

of spiritual dignity and human grandeur were first imparted them by an obscure tribe, subject to the severest rules, and practising the most inexplicable rites. Little will it have been understood that in those rules and in those ceremonies lay the secret principle and true conditions of that power over nature which the Phœnicians seemed to wield so mightily, and the Israelites to exercise so feebly; that while the Phœnician acquired some notions of a Divine order from the regularity of human society, which consequently changed with all its fluctuations, the Hebrew was able to discern a fixed and permanent ground for all institutions and government, in an unchanging personal Being; that while the absence of all domestic ties seemed to give freedom to the movements of the Phœnician, the Hebrew, by preserving the strictness of those ties, was delivered from the restless spirit of emigration to which the other was the perpetual victim. Finally, that while the Phœnician was able to establish a few colonies, and to give to a portion of them forms of government which lasted amidst much conflict for a few centuries, till they were buried under corruptions which were inherent in their constitution from the first, the Jewish commonwealth has exercised an influence over mankind from generation to generation; an influence which is felt and acknowledged the more in each country in proportion as its inhabitants are orderly, peaceful, and happy.

PROPHETIC PERIOD.

FROM B. C. 1271 TO B. C. 600.

If it is a probable supposition that Jewish ideas in the second or national stage of their history exercised an influence over the conquered tribes of Palestine, analogous to that which the patriarchal wisdom exercised over Egypt, it is quite certain that the Jews of the period immediately preceding the rise of Samuel suffered from the sensual idolatry by which they were surrounded, as their fathers in the time of Moses had suffered from the animal worship of their African taskmasters. The form of degeneracy is exactly what we might have expected. It had reached the vitals of national life when the priests became sensual and infidel, when the sons of Eli introduced into the worship of the tabernacle the abominations which were practised in the temples and orgies of Palestine. As every page of Hebrew history and of every other history assures us, such proceedings were a sure prognostic that a crisis was approaching, and that if society was to be upheld there would occur some tremendous visitation through which it would pass into a higher state.

The birth of a boy, not in a miraculous manner, but in answer to the prayers of his mother, who immediately dedicates him to the Lord, is recorded with great solemnity and minuteness by the inspired historian as the index of the commencement of a new era. This boy, we are told, was in very infancy made conscious of a spiritual presence, unseen by the eye, but not removed from communion with man. He was appointed by his invisible teacher to warn the high priest that the sacred office was about to pass from his family, and that defeat and slavery were in store for his nation. And by indications, of which this is a specimen, the historian informs us that Samuel was understood by all Israel to be a **PROPHET**. We have thus clearly and simply pointed out to us the meaning and object of a function which

Grounds of
absolute or
universal
morality as

hended by
the Jews.

Moral and
Metaphy-
sical Phi-
losophy.

had hitherto existed in connection with other offices, but which now first became the characteristic of a distinct and recognised class. The prophet, as such, was neither a legislator nor a civil officer, nor a minister of the tabernacle, though he might by accident be any one of the three. He interpreted the movements of society, set forth the meaning and spirit of the Divine law, showed how the ignorance and transgressions of rulers, priests, and people lead to national ruin. He instructed his countrymen in the fact, that there is a great moral order in the world, which men may violate, but violate to their own ruin. Thus he carried men into a region above positive law, into the deep and inward principles of law, into their connections with the heart of man, into their effect upon his actions. That society is not a machine moving by an impulse communicated to it at creation, or receiving its direction from the chance impulses of human will, but that its primary order was devised, its continual progress superintended by a living person, from whom all law had proceeded, in whose character the truth of all law is embodied; who rules over all the operations of nature, but communicates to men a knowledge of his character, that they may become conformed to it, and of his purposes that they may be his vicegerents in executing them; these were the grand foundation of the prophet's light and teaching. But this high form of personal and political morality would have been worth nothing if it had not been grounded upon a revelation distinct from all that had preceded, though harmonious with them and rising out of them. The belief of a Divine Word dwelling with man and teaching him the ground of his life, in knowing whom only he could rise to the height intended for him, and become properly a man, the ideal of that wisdom and goodness, of which the Jew had seen the indications in the fatherly discipline of the God of Abraham, of which he had heard the announcement in the awful name spoken to Moses in the burning bush, and repeated in the thunders of Sinai, was that which raised Samuel to the dignity of a prophet, and which constituted all his successors the living examples as well as the formal teachers of the people. How these great politicians and profound moralists were taught to express their thoughts, and why they took the form of poetry, are subjects for future consideration. The instance of Samuel and some of the earlier prophets who left no written records enable us to ascertain the essential characteristics of the office before we examine its accidental peculiarities. But another great change was also in preparation, another great step in the political and moral development of the Jewish nation, of which the great crisis to which we have adverted was to be the precursor, of which the institution of the prophetic order was the necessary accompaniment. If our readers have entered into our view of the moral and political ends for which the Hebrew commonwealth was instituted, they will be at no loss to understand the necessity of asserting for a time the naked majesty of law, stamped with the awful sanction of a Divine revelation. Without such a discipline, the grand idea of a theocracy, which is the basis of all political ideas, could never have been received into the mind of that people or any other; neither natural order nor personal morality could have had any practical existence. For national order without positive law is a contradiction of terms. Morality which is not grounded in the belief of absolute righteousness is a phantom of opinion and fashion. But the remarks which we have

VOL. II.

made in our last section may enable our readers to see how important it was to the political system of the Jews, no less than to the ideas which that political system embodied, and which through its means became a portion of the national mind, that at some period the people should be taught to attach the feeling of permanence to the person who administered its law, as well as to the law itself. In no other way could they have learned to feel themselves one people with their forefathers and their posterity. Formal law, however deeply engraved on tablets, or written on parchments, can never convey this impression. It gives each man the sense of his own personal responsibility; it does not communicate to him the sense of union and fellowship. This sense was partially created in the Jewish mind by patriarchal institutions and memorial feasts. Those institutions resting on a recognition of a God of Abraham, Isaac, and Jacob, preserved a recollection of the *past* of each age. But that recollection is imperfect and dream-like, till it is upheld by other institutions which connect both past and present with the future. Such an institution is an hereditary monarchy. An hereditary priesthood had already been established; for from the first it seems to have been intended by the Divine lawgiver to put that strength and permanence on the ecclesiastical institutions of the commonwealth, which its civil institutions were only to acquire by degrees.

A breach in the straight line of sacerdotal succession, the rule being broken for the sake of the principle for which it was established, was one of the indications of the great political crisis which Samuel had foretold. Another, which proclaimed that it had arrived, was the loss of the ark, the symbol of the Divine presence, of national unity. For a period after its restoration Samuel succeeded to the office of judge; his character we have already seen was invested with a dignity which had not belonged to his predecessors; he was, emphatically, the prophet-judge. The two offices were closely connected. The power of distinguishing the boundaries of right and wrong, which appertains to the interpreter of the law, implies, according to the Hebrew idea, that discernment of the mind and will of the lawgiver which is the especial privilege of the seer. Samuel was therefore the perfect judge, fulfilling the meaning of the institution, just as it was about to pass into a higher one. His sons, we are told, did not walk in his steps, and then the wish for a monarchy first arises in the minds of the people. The feeling which dictated this desire is very clearly manifested. The ill conduct of their judges, and the decay of their own faith, led them to regard the majesty of law as a dream, the awful name of an invisible lawgiver as powerless. They longed for a leader of their armies; for one who should not administer the law, but be himself the law. With so slavish a state of mind, reverence for God, the feeling of national unity, the regard for national institutions, was incompatible. The principle of idolatry was in the heart of the people; it must soon have found its expression in all the outward forms of idolatrous worship. The presence of the visible ruler would destroy all faith in an invisible righteousness. Power, not justice, would be the object of their fear. The appointed moral and political teacher of the nation expounds to them the sinfulness of their wish, tells them its consequences, and yet permits them to gratify it. For though itself the offspring of caprice and sensuality, it was the index of a real want in their minds which their Divine teacher had himself placed

Moral and
Metaphy-
sical Phi-
losophy.

4 c

Moral and
Metaphysical
Philosophy.

there; for which he had intended in due time to provide the satisfaction. But first it was necessary that the people should be taught by a terrible discipline what a monarchy created by self-will and upheld by self-will really is; how real that law is which they had supposed only to be an imaginary terror; how it derives its reality from the reality of the awful and invisible lawgiver; how wretched and precarious personal and social life must be where that name is not recognised, and feared, and delighted in. The history of Saul is a most important chapter in moral and political philosophy. From first to last it is an illustration by appalling facts of the connection between an arbitrary government and an indifference to high principles in the people. A slavish habit of reverence for mere power producing national cowardice; this temper in the king producing caprice, vulgar artifice, indifference to great moral and political distinctions, and unconsciousness of any vocation or duties. The two great crimes in the early part of his reign, that of acting as the mere selfish invader of a neighbouring territory, instead of feeling himself the minister of God's justice upon a tyrannical king and guilty nation; and that great civil atrocity of confounding the priestly with the kingly office, are texts on which the political student should meditate long and carefully; on which he will find the history of the ancient and modern world is the instructive commentary. The lesson is not less profitable because it is obvious from the history that Saul had no deep-laid plot to establish an arbitrary government. Carelessness of old landmarks, a habit of thoughtlessness, and indistinction, and self-will, without the least settled intention of evil, were sufficient to make him an oppressor, and destroy the moral feeling of his subjects. But during this self-willed reign the connection of moral and political principles was asserted positively as well as negatively by an exhibition of the blessings of faith, as well as of the miseries of disobedience. In the personal history of David we have the counterpart of the life of Abram. As the one was trained by a singular course of discipline to apprehend principles which were to fit him for being the founder of a family; the other, by a still more detailed and remarkable discipline, was prepared for his future position as a ruler of the nation. Every step in his various and adventurous career was contrived to call forth in him a sense of his personal insufficiency, confidence in the continual succour of a Divine protector; a feeling that he had received from Him a vocation to a mighty work which could only be carried on by His help; a desire to be the image and representative of this Being, in the care which he exercised over His creatures. Thus he was prepared to be the first of a line of sovereigns reigning by Divine covenant and institution, upholding the permanence and unity of the nation, acknowledging the Divine law as the will of all their proceedings, communing with the righteous and invisible Lord, and presenting Him to the people, continually upholding their hopes that He would manifest himself to them yet far more perfectly; would establish a righteous and everlasting kingdom over the whole earth. Such is the idea of a Jewish sovereign, partially exhibited in each king, just so far as he was a faithful and understanding man.

David is always held out to us as the most complete, though still a very imperfect realization of it. In him we find the link between the characters of the prophet and the king; the one exhibits that same moral order

of the nation in acts, which the other expounds in words. The very existence of the king is a prophecy, and the prophet lives to interpret the relations and duties of the king. He is a link between those civil and ecclesiastical functions which must never be confounded, never separated. He cultivates in the nation the feeling of that connection with an invisible Being, which is implied in all the acts of the king, without their contradictions. He is the recluse and the statesman; in one he lives in the most awful and mysterious contemplation, and yet there is no one of his contemplations which does not bear upon the most ordinary transactions of life. In David we have the essentially moral, and the essentially political character, harmonized in one, yet not so lost in each other, but that when the king departs from his right position and breaks the laws which he is bound to obey, the separate function of the prophet shall come forth in another man to rebuke him.

And now that the nation realized the full sense of its unity in the person of its monarch, now that it could look back with delight upon its history, feeling itself the inheritor of the covenant with Abraham, Isaac, and Jacob; with delight upon its law, seeing it honoured and upheld in the person of a living sovereign, and with delight upon its prospects; for the future was pregnant with a race of monarchs, and with One in whom all their glories should be concentrated, and their dominion extended over the earth; poetry came forth with mightier power than at their first deliverance from bondage to be the expression of their thanksgiving, their conflicts, and their confidence. The king himself, he who gives the one heart to the nation, is also the Coryphæus through whom that heart makes its feelings known. That the whole of the book of Psalms is not Davidian is true, but popular language happily expresses the feeling of the collection by giving his name to the whole of it.

The idea of an invisible righteous Ruler in whom the nation subsists, in whom each member of it feels and realizes his own dignity, against whom all selfish tyrants, all the powers of the world, are striving, who upholds each one who trusts in Him against their enemies within and without; in whom the weakest may find a refuge, apart from whom the strength of the strong is of no avail; whose righteousness shall at last be demonstrated to be mightier than all the energies which oppose it; for the continual acknowledgment of whom his image is presented to the nation in every anointed religious king; of whose permanence the prolongation of a dynasty through a number of dying persons is a perpetual witness; who shall finally be shown forth perfectly to man in a perfect humanity;—this may be said to constitute Hebrew poetry. The conflict of naked power with righteousness, of the visible with the invisible, of confusion with order, of the devilish with the Divine, of death with life; this is its subject. And because this is the subject of all human anxieties this book has been that in which living and suffering men in all ages have found a language which they have felt to be a mysterious anticipation of and provision for their own especial wants, and in which they have gradually understood that the Divine voice is never so truly and distinctly heard as when it speaks through human experience and sympathies.

The reign which followed that of David is closely connected with it, yet it is in some sort the commencement of a new era. The idea of a righteous king was

Moral and

Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

that which, amidst all the infirmities of his character, and partly by means of those infirmities, David was appointed to present. No mere feudal monarch, yet asserting the principle of hereditary succession; no head of castes, but the spring and fountain of all the moral, and intellectual, and practical energies of his people, who gave the impulse and direction to their devotions, imparted consistency and meaning to their political order, diffused a sense of justice as the foundation of power over the land, led their armies to victory. It was agreeable to what we might almost call the natural order of things; though we shall have written much in vain if we have not led our readers to feel that human events do not follow a natural, but a moral order; that in the son of this great prince, supposing him endowed with his father's principles, peaceful magnificence should be more remarkable than the higher and more active qualities which he inherited. In place of a warrior poet, possessed with the idea of a righteous Being, and seeking to present that idea in our actions, we have in Solomon the great statesman, meditating on the principles of human actions and feelings, and the relations of the different parts of the system of things to each other and to man, and to their Divine Author—full himself of the idea of wisdom, and holding it his highest glory to hold communion with that wisdom, and to set it forth in his conduct. The books of Proverbs and Ecclesiastes may be spoken of as that which answers most formally in the inspired volume to what is elsewhere called philosophical speculation. In the very beginning of the book, the great problem which is expressed in the word philosophy is announced as the subject of it. It is the search after wisdom and understanding; not in any sense after the wisdom and understanding which are seen in nature; on this we are told that the monarch had meditated, but his thoughts upon it could have had no place in the history of the Divine revelations, and of the education of man into a knowledge of himself and of God; but after the sources of that political wisdom and equity by means of which the character of God is revealed, and the thoughts of man awakened; a search therefore after the foundation of our personal and our social life. Two powers are introduced as contesting for the heart of man, the harlot sense, the phantoms and attractions of the outward world, and the Divine word or wisdom. No abstract notion of propriety or excellence, no formal rules of law, but an actual person, with whom it is possible to hold true and real fellowship, is claiming for its own the man whom a thousand seductive influences are seeking to destroy. If he embraces the one alternative, he becomes a thoughtful, reasonable man, he understands himself, he feels his connection with the beings around him, he enters into sympathy with the order and harmony in which he is placed, he enters into communion with the Being who created the earth and the fountains of waters, who gave to the outward world its form and its beauty, but whose delight has been with the sons of men, who created them for converse with himself. If he takes the other course, he sinks into slavery and death; all personal consciousness, all moral dignity, at last all intelligence, are buried in sensuality, cowardice, superstition. The preface to the book is the key to its contents. The idea of a power upholding the moral order of the world, and leading man by different steps into the apprehension of it, and of a power of nature or death acting on man to degrade and sensualize him;

of two orders of men, one taking the upward, one the downward course of life; freedom and happiness being the privilege of the first; disorder in the faculties and affections, and the final destruction of both being the consequence of the other, may be traced through the whole of it. It is brought out in the most practical manner—in reference to the highest and lowest transactions of man, to the throne of the king, and the scales of the shopkeeper. In every event and act of life the contest between light and darkness is shown to be going forward. Every step may be one which exalts or depresses the character, which weakens its capacities for good, or cultivates and ripens them. It is a book throughout of action and business, continually affronting the notions of those who think that there is one philosophy for the schools and one for the hourly friction of life; showing that the highest principles of philosophy are those which are most real and most directly applicable to practice. It would be manifestly absurd to deduce a metaphysical or moral system, in the ordinary sense of the word, from this book. But, perhaps, we shall find that some portions of the Greek philosophy have scarcely suffered less from the attempt to reduce them into a mere set of dead dogmas than this Hebrew philosophy would. That which is truly required in philosophy, that it should keep one end in view, that it should regard that end as real, yet as one of search or discovery to each new student; that it should lay down a method for that search, that it should show how facts and phenomena of the most various and apparently contradictory kind explain themselves when they are referred to this one principle; these characteristics are all found in the book of Proverbs. Its other great peculiarity is the antithesis of its different sentences. This is no mere accident of a style of writing, it is essential to the idea which the writer seeks to develop, and it is connected with some of those observations of contraries which we shall see hereafter exercised the minds of all the Greek philosophers, from Pythagoras downwards. We have no hesitation, therefore, in setting this down as a Divine type of the future labours of men in this direction. In comparing it with the book of Psalms and with the Prophets, we may discover the formal difference between poetry and philosophy, and may see at the same time how nearly their objects are connected, how inevitable it is that they should often be confounded. The poet contemplates every thing as moving, acting, living; he feels the necessity of permanent forms and principles, not for their own sakes, but as the only condition of their life. The philosopher, as such, inquires primarily after the ground and substance of things, and regards their life as the essential condition or attribute of their substance. Each, therefore, has one vast province assigned to him, not by accident, but by Him who is the all-perfect reason and the founder of all order, and each by the same law has his own prescribed mode of expression, which by degrees he discovers for himself. Verse, which, as we have seen, is the first garb of human thoughts, after they have thrown off the loose drapery of conversation, that which in union with music expresses the sense of a living harmony and orderly succession in things, is soon found a most inapt vehicle for describing those fixed forms and accurate distinctions with which the philosopher is concerned. He therefore finds out a method of discourse in which the conversational manner of the historian is combined with the dogmatic dignity of the lawgiver. He is

Moral and
Metaphy-
sical Phi-
losophy.

the inventor of those rigid principles of discourse which are again expanded into a style, and mixed with some poetical elements by the later historian, and which suggest the formal limitations as the poets suggest the living laws of grammar. The idea of philosophy must impregnate all poetry which arises after the commencement of civilization, or it is in danger of becoming the reflex of temporary forms and passions; but poetry never can be written for the purpose of expounding philosophical principles without losing its proper nature. On the other hand, the living feelings of poetry must impregnate the mind of the philosopher, lest, instead of observing substantial principles, he should only take notice of the dead shapes of things; but the philosopher cannot aim at the vital forms and expressions of poetry without forgetting his own true function.

The book of Ecclesiastes, the other great specimen of sacred philosophy, is also not poetical. In the Proverbs, wisdom is brought before us as a personal object, wooing the man to its embraces, delivering him from all his seducers, satisfying him with its own perfect love. It is addressed, as we have seen, to a man entering upon life who has as yet had no experience of good or evil influences.

In the book of Ecclesiastes we have the mental biography of a man who has merely exulted in knowledge as a power, which was not to deliver him from the world, but to make him the master of it. In the very first verses of the book, he tells us the subject of it—it is vanity; the world and all its proceedings regarded out of their connection with God; man attempting to recreate by his wisdom that which he finds established—making himself the centre. The maxim of the book is this, you can find no centre of things in the world around you, you yourself are not the centre of the world; you must refer yourself and all things that you see to a Being above you, or all is vanity and vexation. When we come to investigate the problems of Greek philosophy we shall find how useful this experimental book is in the exposition of them. Many of the forms of thought prevalent in the schools of Greece have their germ here. We have not the theory, but we have the feeling and experience which were its parents. The sense of restlessness and confusion in all things continually encountered by perceptions of a mysterious order; the alternate attempt to glorify the senses and the intellect at the expense of each other; the generalization of the rules of life from experience which seem satisfactory, and then, as new facts present themselves, give place to their contraries; the attempt to find a key to the problems of nature and society, and the constant discovery that there is something in them which baffles our speculations. These are hints which every student will at once acknowledge to be the heads or titles to long and weary chapters in the history of Moral and Metaphysical Philosophy. In fact, the more we study the dogmas of sects, in different periods of the world, and attempt, as Mr. Hume has done, in reference to later Greek speculations, to find out the facts of experience and the prominent feelings which gave the character to each, the more we shall acknowledge the truth of this book, and its utility in translating mere notions of the understanding into the real language of the heart.

Among the poetical books, the book of Job is the one which most nearly approximates to the philosophical character. On this account partly many modern writers sup-

pose that it belongs to a much later period of Jewish history than the time of Moses, or even of David. The usual answer to such an argument, that it might please the Divine wisdom to give that form to even the earliest writings is clearly inadmissible, at least by those who recognise the principle of a Divine education, and perceive throughout all these books the traces of a wonderful order in that education; and as either hypothesis must depend merely upon internal evidence, the authority of the Jews being, it is believed, not decisive either way, there can be no reason for retaining an opinion respecting the early date of this book, which was probably itself a departure from some older one. Be that as it may, the book of Job presents us in a dramatical form with a history of a man, the specimen of his own nation, the specimen of humanity, struggling under an overpowering weight of calamity to discover the cause of human misery, how its existence is compatible with the mercy of God; the sense of inward evil, fighting against the feeling that in some sense he is a righteous man, surviving amidst patient hope, doubt, and despondency.

The reader is taught in a preface or prologue that he is about to view the conflict between the spirit of good and evil, each wrestling for the heart of a man. The man is then introduced in his lowest depth of suffering, still holding fast his faith in a God of justice and righteousness. In his misery three friends come to him, who set before him the vision of a God of mere power, delighting to baffle and confound his creatures, and between whom and them there exists no bond or sympathy.

In the vigour with which Job repels this view of the character of the Being whom he worships consists the grandeur of his arguments, in his attempts to reconcile this idea with actual appearances, and in his uncertainty whether to call the evil or the good within him, *himself*, consist their confusion. He had acknowledged the righteousness of God, but he had not bowed before His wisdom. God answering him out of the whirlwind overwhelms him with a view of the mysterious order, disposition, and harmony of the natural world, brings him into an awful sense of his insignificance, and into a still more awful understanding that in himself, separate from the Being who had thus vouchsafed to converse with him, he was unrighteous and unclean. From this state he is restored to all his former peace, joy, and prosperity. This is the Jewish drama, and it seems to us to present the very idea of a drama. To identify it with other specimens of that species of composition would be monstrous; equally monstrous, we conceive, to reject the notion which has so universally prevailed, that it has some relation to other dramas. The nature of that relation our past remarks will have made sufficiently evident. It is as it were the essential archetypal form of dramatic writing; as if we should suppose that a general, by selecting a few of his men to go through certain evolutions for the purpose of illustrating his general system of tactics, gave the first hint for the game of chess.

Of course it is not for the purpose of explaining the nature of poetry merely as a branch of art that we make these remarks. But the history of poetry, and in a less degree than the other fine arts, is so interwoven with that of man's moral and metaphysical speculations that we can only give meagre and doctrinal views of the one, without frequently taking notice of the other.

Moral and
Metaphy-
sical Phi-
losophy.

The book of Job in itself awakens some of the most anxious questionings of the human heart, and yet we think its importance is not appreciated unless it be viewed as the Hebrew form of that drama which in Greece was the great connecting link between the active and speculative life of man. That which has been called the Epical poetry of the Hebrews we regard precisely in the same light, not to be tried by any inferior standard, but the ideal by which the nature of all the specimens of a similar kind of composition existing elsewhere may best be ascertained.

That mysterious person, the unseen guide and teacher of man, whom Solomon had contemplated as the source of all wisdom to kings and rulers, to labourers and handicraftsmen; this awful person, as Mr. Coleridge has remarked, "is the hero of the Hebrew Epic." How all passing events, all convulsions of empires, all changes of dynasty indicate his presiding government, illustrate the eternal laws of justice and righteousness, by which he is ruling; how he has chosen one nation to be the centre of the universe, that its kings might exhibit the pattern of his justice, and wisdom, and condescension to man; its priests, that holiness and purity of character to the likeness of which he would raise man, the whole order civil and ecclesiastical, the deep inwoven harmony of that scheme according to which all the ages of the world had been disposed; how the violations and transgressions of this order, by the perverse will of men, their refusal to be the witnesses for God to the nations, the lust and pride of rulers, the selfishness of priests, the ignorance of the people, were preparing the way for the dissolution of their commonwealth; how yet the purpose of that commonwealth would be fulfilled, because it stood not on the caprices of men, not in the faith of a peculiar people, but had its foundation in the "fact" of an union between God and man, in the person of the Mediator, in the certainty that He was the bond of all society; how this Being would finally be manifested to man; the completeness of his union demonstrated; how by transcendent arts, yet beheld only in the distance, reflected in imperfect human mirrors, the full meaning of this incarnation would be accomplished, and the foundation laid of an universal human fellowship, grounded upon the fellowship between man and God:—these are the principles by uniting together political facts with political science, yet appealing to the hearts, and making themselves intelligible to the faith of the poorest sufferer, of the most humble wayfarer—because they set forth the character of One, with whom he, as much as the ruler of his land, was permitted to converse—which found their expression in the Hebrew Epical Poetry.

Each inspired prophet appears at some peculiar national crisis to expound the principles of the Divine government in reference to that crisis, and thus to bring out into manifestation a scheme of moral order so necessarily applicable to all times, that in each new age, each particular event, however limited by the words of the prophet to the period and nation for which he wrote, should be supposed to be some one then in progress or preparation. Every new prophet in this practical way was appointed to present some new sign or phrase of the Divine character, as the one most needful at that time to be contemplated, some new principle of that scheme which can only be seen to be complete and circular when it is beheld by the light of a future dispensation, and by that light only, perhaps, when the eye has been purged from all the films of mortality.

Interval between the third Hebrew Period and the Commencement of Greek Philosophy.

Moral and
Metaphy-
sical Phi-
losophy.

We spoke at the commencement of our discourses of those monarchies, built upon the worship of power and of nature, the commencement of which is referred by the Hebrew historian to the Tower of Babel, and against the principle of which the family life and national order of the Hebrews were a formal and continual protest. What mutations these monarchies underwent, the deeds of their monarchs, the changes of their dynasties through many centuries, are not recorded in any authentic document, and would not be worthy of repetition if they were.

Till some principle gave vitality to their dead tyrannies there could not be enough of social order or moral life among them to produce records. Nearly all the prophecies are connected with these monarchies and their relation to the Jewish people, but it is obvious that the Chaldean dynasty, whenever it may have been established, was very different in kind and character from those which had preceded it. A race of magicians, the study of astronomy, magnificence and decoration in buildings, distribution of provinces under Satraps: all these are indications of a different stage of society, a character of humanity which it is impossible that any of those earlier savage despotisms could have possessed. To what were such habits, studies, and institutions owing? and do they correspond to the third stage of Jewish education, as the changes in Egypt did to the first, and those in Phœnicia to the second? Every thing we see in the Jewish mind at this time was leading to the idea of a mysterious Being, presiding over human society, directing the movements of the external world, ruling and disciplining the hearts of men, and binding them together. There was an universality in the views into which the Jews were now led, which, though it had grown out of their former relations, was very different from them. The parody of this universalism, that false image of it, which a nation not agricultural like the Egyptian, with no facilities for commerce like the Phœnicians, living under a clear and beautiful atmosphere, used to absolute government, and educated in notions of conquest might exhibit, is exactly that which we know to have been the worship and the government of the Chaldeans. Far removed from the animal idolatry of the Egyptians, almost as far from the human worship of the Phœnicians, the Chaldean saw in the powers of the world, and especially in the stars over his head, the images of that all comprehending and all observing superintendence which the Jews were taught to attribute to the unseen God of righteousness, the God of their fathers. These mighty dynasties, who ruled the world below, exercising so great an influence over all the operations of nature, must likewise have some mysterious connection with the destinies of a being, who, even while he was humbling himself below the powers of the world, could not help feeling himself more important than all. Hence the hint for a science of astrology, built up partly on an observation of natural phenomena, partly on principles connected with the heart and conscience of man—projected outwards to meet these phenomena—partly upon that recognition of an absolute Divine supremacy which the Jewish faith, acting upon old Chaldean notions, had called forth. Such worship will always be connected with grander conceptions and occasionally with a deeper prostration of mind than either of the other forms can be. It will

Moral and
Metaphy-
sical Phi-
losophy.

be compatible with wide schemes of conquest, with magnificent cities, with buildings, not suggested by notions of utility, but claiming admiration for their own sakes. But in those forms of art which refer to the countenance and proportions and life of man it will be deficient; it will have (in this respect resembling the Egyptian) a sacerdotal, not a popular literature; all those energies which lead to self-reflection will not so much be crushed by outward power as never awakened. The principal qualities developed will be a sort of political sagacity or cunning; the principal moral virtues will be magnificence and clemency. These are something like the characteristics noted in the Scripture as belonging to those Asiatic monarchs, of which the Chaldean may be called the first specimen; the first, that is to say, in which the savage features of the Babel system were softened and subdued by a more mild and human expression. The thoughtless and ignorant Jew who travelled into these lands, and admired their fine palaces and august natural temples, little knew how much the neighbourhood of his own despised tribe tended to produce the cultivation which raised those palaces, and inspired those grand conceptions; little knew when, on going back to his own people, he imported the Chaldean speculations and the Chaldean horses and chariots, how much he was labouring to undermine the principles of that cultivation, and to destroy the only principle which could ever uphold it, or give it further extension. The neighbouring idolaters of Syria, the intercourse with Egypt, too frequently resorted to as a protection against the older Assyrian monarchy, had done much to sensualize and to animalize the Jewish people. Family life had decayed through popular grossness, through neglect of the patriarchal institutions—of the memorial of feasts and holy traditions which connected them with the past—national law and order had been undermined by the commercial spirit. There wanted but this Chaldean imposture, the substitution of grand notions of nature for a belief in God, to complete the overthrow of the national character. The corruption advanced gradually, amidst warnings and exhortations, embodying the deepest political wisdom ever expressed in human language. At times, through the instrumentality of a righteous king, sweeping away the forms of superstition, and restoring the forms of the individual worship, and drawing them to their proper centre, it was arrested. But when this Chaldean element had been introduced, the complaint was near the vitals of the state. The destruction of groves and high places might remove the temptation to Phœnician idolatry; this worship of nature was inward, consummate apostasy. A subjection to the people in whom it had reached its height; an experience of that all-crushing despotism which always had coexisted, and always must coexist with that system of faith which recognises no real bond of sympathy between the worshipper and his God, was the method which the Divine wisdom chose for the discipline and restoration of the fallen nation. During that period of captivity the prophet Ezekiel felt, with no exaggerated nationality, that the glory of the earth was departed, that no one formal, practical witness for righteousness, and truth, and order was left upon the earth, and that nothing but a faith which, nourished by the forms of his country's worship, enabled him to look beyond them, could withstand the dreadful conclusion, that mankind would be henceforth left without a remembrance or

a hope to choose its own delusions, and be the victim of its own ignorance.

The Scripture history, however, which has traced so far the progress of human education, does not leave us to fancy how these melancholy dreams were refuted, and the faith which the holy man was enabled to maintain in spite of them confirmed. A book, the removal of which from the canon, according to the peremptory sentence of some modern critics, will at all events leave a most inexplicable chasm in a history which has hitherto been continuous, and which, with this addition, and that of the two or three prophets after the captivity, offers an intelligible link between the records of the chosen people and those of other nations subjected to a different discipline—this book shows how that knowledge, of which the Hebrews were the depositories, influenced the mind of Chaldea. All such influences must of course have acted directly upon the monarch, and through him upon the people. The discovery of a wisdom speaking to the heart of man, which surpassed and overreached the superstitious guesses drawn from the observation of phenomena; the grand idea of a Being ordering the course of empires, not by the motion of the stars, but with reference to a moral end; the idea of a Being of foresight and order, interested in man more than in nature; an object of his trust, and able to protect him against the powers of nature and man—these, with a severe and harmonizing discipline, are said to have wrought upon the mind of Nebuchadnezzar, to have brought him to honour and fear the God of righteousness and not of nature, and to have diffused a mild and gracious spirit through his government.

Although it is not the proper business of this Treatise to defend the genuineness of these documents, or of those which sketch the history of Asiatic monarchies, from the Chaldean, through the Medo-persic of Darius, and down to the Persian of Cyrus, that branch of the Alexandrian monarchy which was established in the persons of the Seleucidæ; yet we may be permitted to remark, that if the forger of these histories and prophecies lived, as is supposed, in the reign of Antiochus Epiphanes, he possessed a most miraculous faculty of clothing his invention with the forms of an age in which he was not living, and a most unhappy talent of making it inapposite to the period in which he wrote. The Syrian monarch was Hellenized throughout. Greek worship, Greek taste pervaded his mind and kingdom, and these it was his ambition to set up in Judea. But the scenery of the book of Daniel is throughout Oriental. The spirit of Asiatic monarchy breathes throughout it. To suppose the heart of the Maccabees stirred up by such a composition is reasonable enough, if it were found among their sacred books. But the man who should have set down to write it for the purpose of exciting them must have been a madman as well as a liar, incapable by his dishonesty of patriotism, no less incapable of arousing it in others, by his ignorance of the feelings and circumstances to which he addressed himself. Whether either of these suppositions are consistent with the method displayed in the book, a method as fully recognised in the objections of Porphyry as by any Christian panegyrist, and whether consequently the difficulties from internal evidence, which has been chiefly resorted to, are not greater for rejecting the book than for retaining it, we leave for our reader's consideration. But if we admit its truth, we are authorized to assert that, as a fact which reason and experience

Moral and

sical Phi-
losophy.

Moral and
Metaphysical
Philosophy.

would have warranted us in expecting, that as Jewish influence gave her early feudal institutions to Egypt, gave that impulse to Phœnicia which converted it into the first mercantile nation of the world, so it also was the means of converting the Babel monarchies of the East into those comparatively humanized and orderly despotisms which Aristotle did not consider unworthy of being treated as organic polities.

Thus, then, we have taken a view of the progress of Moral Philosophy in that nation in which we believe it to have been cultivated by a Divine Instructor. We have seen in what way family life, political institutions, experimental history, and the direct teaching of ecclesiastical ordinances trained the chosen people to a knowledge which raised them above nature, enabled them to realize their position as men, brought them to a sense of the law under which man exists, of the tendencies which dispose him to violate that law, of the power by which he is preserved in obedience to it, of the consequences which result from its violation. The feeling of being brought into a system of moral order different altogether from that natural order to which he saw all things around him subjected, yet one not less real, not less permanent, not less, but more emphatically, the expression of the will of a personal Being—who was leading him up, through the framework of outward laws and institutions, into the apprehension of a still more deep and mysterious order, in a still more universal sense belonging to man; the manifestation of which would in some remarkable way be connected with the manifestation of himself—was wrought not by violent inculcation but by gradual processes of experimental discipline into the heart of the Jew. The grand and awful question respecting the nature of evil, its relation to man, its relation to nature, its relation to God, was made known to him by the same living process. Habits of reflection and meditation were, as we have seen, not the ornaments of his character but parts of its very substance. His practical life was a supernatural life, he could not act without thoughts, which carried him above nature, above himself; he could not fight battles, or rule kingdoms, or pronounce the most trifling judgments, but under a sense of mysterious government and fellowship. Yet he was a man of ordinary vulgar passions, not different in any one respect from his fellows, teaching them as much by the sensuality into which he constantly sank, as by the heights of wisdom and moral grandeur to which he was afterwards raised, the mystery of manhood, that debasement is not its law, that dignity is not its nature, that a man may be brought into such conformity, such sympathy with his law, that he shall feel dignity to be his rightful inheritance, debasement his natural bondage; that this state is only possible when he beholds his dignity in a Being above himself, united to himself and to his fellows; when he can disclaim every thing selfish as not his own, as the relics of an imaginary and false condition out of which he has been delivered.

GREEK PERIOD.

Preliminary Observations.

Commence-
ment of
Metaphysical
Philosophy.

If we would distinguish the subject on which we are about to enter from that which we have been examining hitherto, we must not content ourselves with saying that the Hebrews were the subjects of a Divine education,

and that the Greeks were left to follow the workings of their own minds.

Moral and
Metaphysical
Philosophy.

The evidence of all history, had we no higher witness, would lead us to believe that the spirit of man is never awakened to any earnest or continuous inquiries but by an influence superior to itself. From the Hebrew Scriptures we learn that all human society is so constructed as to be an instrument by which the Divine Teacher acts upon man. Human relationships, laws, political events, are (as we have seen) the agencies whereby man is led to seek after a knowledge of his Maker and of himself. Wherever these exist, we may be sure that this higher influence is at work, whereby their existence is recognised and felt to be important, there we may be sure it is strongly at work. We are bound, therefore, to suppose that it was not wanting in Greece, and the earnestness and continuity of the speculations in which her sons engaged add irresistible force to this conviction. It is not in the absence of Divine cultivation, but expressly in the absence of that kind of cultivation which takes place by means of a Divine revelation, that we seek for the difference in the two nations. The mind of the one is led to seek after some centre to which all that it beholds without, all that it feels within, may be referred; the other has a centre given with which it is taught to connect every observation and every conscious act; the one gropes in all directions after its object, the other is restricted to meditations on the relationships of man; the one ardently desires to understand the meaning of the powers which it finds in itself, whence they proceed, and to whom they belong, and under what limitations they exist; in the other the sense of power is either merged in the feeling of responsibility or else realized only in the outward acts which manifest it. We have here indicated the characteristics of the Greek philosopher—he is seeking for a centre. He is seeking this centre in nature, in the instruments by which man studies nature, in his own thoughts, in institutions. He is seeking with an ultimate reference to the discovery of the nature and limitations of his own faculties. Now here, it will be seen, is that kind of inquiry which, in the outset of our sketch, we called *metaphysical*, and which we distinguished from *moral* by this characteristic, that it was suggested by the desire to discover the foundation of our *powers*, not the foundation of our *relationships*. The Hebrew and the Greek we consider the originating points of two great lines of thought. We shall find these lines continually approaching, moral discoveries implying metaphysical truths, metaphysical theories seeking a ground in morals: at Alexandria we shall find them attempting to form a *speculative* union; in Rome we shall see an unsuccessful, though very interesting, experiment to combine them in *practice*.

Before the history of ancient philosophy closes we shall endeavour to show where they did find an actual meeting point; and then we shall be able to trace with a greater feeling of security, and with a better hope, the course of modern philosophy, seeing more clearly both the point from which it starts, when it is moving with retrograde steps, when it is advancing, and what is its ultimate goal.

Having made these remarks, it is scarcely necessary to explain why we do not assign a separate division of our work to the philosophy of India and the other Oriental nations. We have proposed to ourselves the task of tracing the progress of thought and inquiry. Now the sacred books and poems of India may contain

Source of
Greek Phi-
losophy—
India.

Moral and
Metaphy-
sical Phi-
losophy.

vast materials for thought, the results of many speculations, but no one will contend that they afford us the least clue to a discovery of the method which the human spirit has followed in its search after foundations of things. We hold it better, therefore, even for the purpose of illustrating these remains or deposits of an unknown antiquity, that we should not be tempted by them to leave a path in which we can trace a regular series of clear and definite footmarks. They will be understood far better when they are contemplated as the chaotic mass out of which more harmonious speculations have been disposed, than where they are studied in their own rudeness and incoherency.

To the purely physical philosopher the cosmogonies of India must always have an interest because they are obviously attempts to explain the meaning of observed phenomena. They cannot be neglected by any writer on theology, for they exhibit one of the forms in which the feeling of a superior power and the necessity of worship find expression. The moralist is struck by observing how thoughts of justice and goodness insinuate themselves into this physico-theology, and give it all that it has of consistency. The metaphysician observes with a more melancholy interest the hopeless attempts of the spirit of man to disentangle itself from the confusions of sense. But neither of the last can feel that these cosmogonies directly belong to his province, for they neither indicate a search after the law of our connection with other men, nor after the nature of the faculties which we find in ourselves.

It is, however, a question of some interest whether the Greek philosophy is at all derived from these Oriental sources. On the doctrine, which was formerly much more prevalent than it is now, that the Greeks were indebted for part of their knowledge to Hebrew seers, we need not say many words. Were the notion built upon any alleged facts, it would become us to consider these facts, and only reject the conclusions from them, if we found that they were not proven, or that they were neutralized by more powerful facts on the other side. But as no one has pretended to do more than affirm the possibility of an intercourse between certain Greek philosophers and certain of the inspired writers, or the possibility of their attaining to a secondhand knowledge of the inspired books, we have only to encounter the theory which has given these affirmations plausibility, that unless we admit them there is no way of explaining how the Greeks became possessed of their wisdom consistently with our reverence for the Jewish Scriptures. Now we stated by anticipation our objections to this theory, when we contended, first, that these Hebrew books themselves most clearly and consistently explain how the Greeks might acquire all the thoughts which they did acquire without any external teaching; and, secondly, that we can best understand these thoughts and those which were imparted to the Hebrews by supposing them to have started from different points, and to have proceeded in a different direction. The other controversy, whether the Greek speculations can be traced to an Indian, or if not to an Indian, to any Eastern source, must be settled by an examination of Greek mythology, for through this, and not immediately the foreign influence, must have reached the Greek philosophy. Such an examination is on other accounts of importance; for though mythology in itself, and the period which is called the mythical or heroical, cannot, for the reason we have stated, be considered as belonging

to the history of human inquiries, yet the influence which it exerted upon the later development of the national mind ought not by any means to be overlooked.

The mythology of Greece has three stages, answering to those we have taken notice of in the Hebrew education, and which we have seen respectively paralleled in Egypt, Phœnicia, and Chaldea. Professor Müller, with evident truth, has remarked, "that we may trace in the mythology of Homer clear indications of an earlier worship." This he supposes to have been the worship of natural objects. For general reasons, which we have stated at large already, we object to this doctrine, and we do not think it is borne out by the evidence to which he himself appeals. In the phrases "Father of gods and men," and all those phrases and stories which ascribe family relationship to the gods, whether among themselves or with men, and not in the epithets "Cloud-compeller," "Thunderer," &c., we discover the leading characteristics of the older and simpler faith. Respecting the second stage there is no controversy. It is clearly the national or political stage. The council chamber of the Argive chiefs is transfigured into the council chamber of Olympus; the gods are kings and chieftains; they acknowledge laws and enforce them. This is Professor Müller's own opinion, though by what means such a worship could have been superinduced upon a mere natural worship he does not undertake to explain.

In neither of these stages of religion can we trace the slightest resemblance between Indian and Greek ideas. In India there is the constant want of a human moral foundation; in early Greece there is scarcely the slightest attempt at speculation upon the origin of world or the principles of things.

If we take one of the clear harmonious pictures in Homer, and compare it with the monstrous conceptions of the Indian cosmogonies, we shall be at once convinced that no possible resemblance can have existed between the spirit of the two nations at this period, or the sentiments in which it expresses itself. The Greek himself, as we have already hinted, was more successful in discovering a connection between his own religion and that of other nations. It may be quite true that the family mythology sprung up in the mind of the Pelagian herdsman without any external culture. Still it had its counterpart in the faith of the Egyptian herdsman. It may be that the Greek citizen had no need of being taught by others to worship Divine legislators and monarchs. Still he might find a similar worship among the political Phœnicians, only there was this remarkable difference, that he did not stand still at the Egyptian point of cultivation, losing that which he had attained in animal grossness; that on the other hand he did not commence at the point of civilization from which the Phœnician thoughts took their rise, and thus sink into the mere cunning commercial sensualist, but that the national branches grow out of a fair and family trunk, which contained indeed within it the seeds of its own decay, but contained also a living and healthful sap. To this difference we consider it as principally owing that the Greek was able in this second stage to clothe his thoughts in manly and lasting poetry. But as these two steps of Greek mythology are obviously in no degree connected with the mythology of the East, so likewise they produced no direct effect upon the philosophy of the nation. We cannot determine, therefore, till we have

sical Phi-
losophy.

Mythology

Moral and
Metaphy-
sical Phi-
losophy.

Dionysus.

considered its third stage, whether this philosophy was not impregnated with Indian ideas.

It has been often remarked that the name Dionysus does not occur in Homer. Now, if we consider only the dignity which this Dionysus afterwards attained as the patron and inspirer of the Greek drama, we shall not want any further proof that his introduction into the Greek pantheon was the symbol of a most important era in Greek feelings. And the more we meditate upon his character and offices the more we shall be struck by the new region of thought to which this new divinity belongs. We do not mean that there is no indication in Homer of the kind of feeling out of which this worship must have grown. His heroes are constantly spoken of as inspired with courage and counsel by some Divine protector or protectress; and the idea of constant communication between the Olympian gods and men here on earth, denoted by visible signs, but really carried on between the heart of the man and the Deity, is the very soul of the poem. But the acknowledgment of a Being who is emphatically the inspirer, the lifegiver,—who, therefore, becomes connected with the most secret emotions and energies of the human spirit, and whom the worshipper inevitably associates with all the movements and activities in the world which he sees around him,—this carries us out of the circle of local gods dwelling on a certain Thessalian hill into strange indefinite apprehensions of a presence to be felt and realized rather than beheld or understood. Every one knows in what grotesque forms this awful feeling enshrined itself; the god becoming identified with that which was the aptest outward symbol of internal life and joyousness, and the mind of the worshipper disporting itself in all fantastic combinations and contrasts, as if it were struggling with a thought that overmastered it, and found its revenge in inventing these ludicrous natural types of the conqueror. Much, doubtless, of all that is deepest and strongest and most contradictory in man may be found embodied in the history of Bacchus and the Satyrs. Yet this was not all. The Greek himself felt that there was something in him which no stories could tell, no pictures embody. He had need of *Mysteries*, and these mysteries spoke not to the initiated only, but to every one who had heard their name, and knew that they existed, of something about him, above him, within him, which language could not interpret.

Mysteries.

We have no thoughts of entering into the inquiry what these mysteries signified, an inquiry which would scarcely have been mooted, or at least not pursued with so much theoretical exclusiveness, if their real influence upon the mind of the people had been understood. We can easily adopt all the explanations that have been given of them, and acknowledge them all to be true, and yet after all believe that the power which they exercised arose mainly from their witnessing to the truth that there is something most nearly and intimately concerning us which is above all explanation. Consistently with this idea the mysteries may have spoken of a unity in which all separate things begin or terminate, of a Divine power which could not be expressed in images, of a Divine element in man, of the secret operations in the womb of the earth. Whatever a man found too large for his thoughts to comprehend, this, whether it were in God, in himself, in nature, became the mystery which he connected with the rites and symbols to which he was introduced, or of which he heard dim

rumours. Indeed, it is perhaps the very difficulty to know where precisely this mystery was—in nature, in God, or in his ownself—which created his anxiety; only this he knew, that it was somewhere, and that not to own it was to deny himself.

How this Dionysiac worship and these mysteries were connected with the feeling that gave birth to *cosmogonies* we may not at once be able to discover. But it would seem that the characteristic of the state of mind which this faith expressed is a feeling of the latent powers in man and in all nature. It would seem, also, that the period during which this change in the national mind took place, was one in which pictures of human political life, such as Homer presents us with, must have lost their charm, because there was nothing in the actual circumstances of men with which they could be compared. In the feeling and literature of such an age there will have been inevitably a bias towards physical theology. In such a time the works attributed to Hesiod may have been produced; for though the *Weeks and Days* and *The Theogony* may not have proceeded from the same author, the common name given to them seems to show that they belong to the same period of moral cultivation. Here, then, we find a point of coincidence between the habits of thought in Greece and in the East. But the resemblance is not surely sufficient to prove that the one was derived from the other; it is not greater than that which we have observed between the two earlier states of feeling and those prevailing in Egypt and Phœnicia. In fact, it is precisely the same kind of resemblance; in each case the Greek, exhibiting a steady and remarkable growth, and passing for a time into those conditions of thought and feeling which became the fixed and hopeless prison-houses of the people with whom we compare him.

From the moment political feelings were reawakened in Greece, that bias towards physico-theology, of which we have spoken, received a mighty counteraction. Then we hear of the Homeric rhapsodies being read, admired, collated; then the old local mythology recovered some of its former life, and the new idea which had threatened to exclude it became blended with it. Yet that idea was by no means lost. It had even acquired new power from the political life which seemed to threaten it with destruction. The mysteries were honoured and accounted most precious by the statesman.

Again, the idea which was contained in the worship of Dionysus gave birth to the deepest thoughts and the noblest literature. It informed and possessed the mind of the poet, enabling him to realize, and making him eager to express, thoughts which belonged to his kind even more than to himself. It worked also in the mind of the philosopher, making him feel that there was something in himself which needed explanation; leading him to connect the world within with the world without, and to hope that, by some means or other, by studying the phenomena of nature, by applying the new found sciences of mathematics and astronomy, or by exploring the recesses of language, he might find the solution of the enigma.

Ionic School.

About the time that Judea sank into a province of Ionian the Great Babylonian Empire, the philosophical spirit school first began to manifest itself among the Greek colo-

losophy.

Cosmogonies.

Moral and
Metaphy-
sical Phi-
losophy.

nists on the Western coast of Asia, and in the South of Italy.

Many circumstances may diminish our surprise at the fact that in Asia, rather than in its proper home, the Greek genius should have put forth its first buds. The Greek colonist was on the very soil which was hallowed by the traditions of those elder days when European wisdom, exerted in a righteous cause, triumphed over the pride and luxury of Asia. Seeing himself constantly surrounded by men whom he felt to be his inferiors in sagacity and individual prowess, who formed only the elements of a massive Oriental despotism, he would be inclined to exercise all the wit which was his hereditary endowment, and which the exertion of maintaining a position in a foreign land must have ripened. He had already cultivated his native resources by commerce and by travelling. He kept alive in his new country those tribe distinctions which united the family feeling to the national. His political talents were called forth in the effort to preserve the municipal government in each city, or to maintain its combinations and its rivalries with its neighbours. The conflicts through which the mother-country was working its way to settled freedom had terminated here in the rule of particular tyrants, men promoted by their shrewdness, activity, and political wisdom; who rather called forth these qualities in others by their example than discouraged them by their jealousy. The genial Asiatic climate, which gave such sweetness and softness to the dialect of these colonists, imparted also a portion of its influence to their character. It quelled the excessive restlessness without extinguishing the energy of their minds, and thus disposed them more readily to exert that energy in inquiry and contemplation.

On the coast of the Ægean the influence of the Ionian tribe was predominant; the colonies in Southern Italy were almost exclusively Dorian. There the genius for order and legislation which belonged to the tribe had already displayed itself, and the names of Charondas and Zaleucus are surrounded with an obscure traditional dignity like that which belongs to Lycurgus.

Yet it seems that the philosophical spirit could not exert itself in either country, till the vivacious and volatile temper of the one tribe had acted upon the sober and severe wisdom of the other. We shall hear presently how an Ionian travelled into Italy, and what a new character was imparted to his inquiries by the disposition towards order and fixed institutions which he found prevailing there. And it is equally true that the commencement of directly philosophical investigation among the Asiatic Greeks was preceded by the appearance of a set of men who were evidently political sages, whose thoughts were all more or less connected with practical human life, and who embodied them in terse sentences, such as the Spartan delighted in, but were very far from the free habits of the rival tribe. And we think our readers will discover proofs in the short sketch which we shall give of Ionian philosophy, (the subject which deference to common practice, as well as a desire to exhibit the gradual movement of civilization from the East to the West, compels us first to notice,) that a human element did enter most strongly into it even when it seemed exclusively to consist of speculations on nature. The portion of it which relates to man may seem insignificant when compared with that which treats of the external world; but if we look carefully, we shall find that this is really the

centre of the whole, and that, when we refer every thing else to it, each system becomes internally coherent as well as connected with the rest.

Thales is by universal consent the father of Greek philosophy. The place of his birth seems well ascertained, there is great doubt about the date of it; but all authorities would seem to place him in the period during which the Ionian cities were in their most flourishing condition, and his own city of Miletus conspicuous among them. Some traditions would represent this circumstance as a matter of indifference to the philosopher, others speak of him as taking the deepest and most practical interest in the affairs of the colonies. These reports are easily reconciled; a meditative man will always seem a recluse to the world, even if his thoughts have the most direct application to its business. The mere fact of *Thales* being included among the seven Sages of Greece, would prove that he was not merely devoted to physical speculation, for their fame is entirely moral and political. The sayings attributed to *Thales* are so expressive of the spirit which informed all Greek philosophy, that they may seem to have been dramatically assigned to him as the traditional founder of it. But the sentences, "Know thyself," "All things are full of the gods," will at any rate prove that his countrymen supposed the foundation of his philosophy to be in some sense spiritual. Still more strikingly is that feeling manifested in his reported maxim, "That all things are open to the gods, even our thoughts;" for it is an absurd supposition of Bayle, that he uttered such sentiments merely to disguise his real opinions. Very probably he never uttered them at all; if he did not, they are indications of his character; if he did, it is a gross anachronism to fancy them insincere. *Pythagoras* concealed truths which he thought too sacred for the multitude, but only the later schools adopted any contrivances for the purpose of hiding their atheism.

Nor do we think these opinions of the Greeks at all inconsistent with the speculations which they attribute to *Thales*. Water is the first principle of all things; this was the central doctrine of his system. Now, if we may believe Aristotle, this thought was suggested to him not so much by contemplating the illimitable ocean, out of which, as old cosmogonists taught, all things had at first proceeded, as by noticing the obvious fact that moisture is found in all living things, and that if it were absent they would cease to be. It is evident from the same authority that he connected this observation with facts which he noticed in himself; nay, we think it may quite reasonably be inferred that Aristotle felt this analogy to be really the most important point in the theory. Just what this moisture is to the ground, necessary to its being what it is, yet not the ground itself, just such a thing do I find in myself, something without which this body would not be what it is; a seed of life within me, something which, if it were withdrawn, this, which now seems so firm and solid, so active and vigorous, would become a mere dry, useless husk, ready to fall into pieces. Such we suppose to have been the sense, the feeling, contained in the opinion of *Thales*. We do not mean that he looked upon water as a symbol only of his soul: to imagine this would be to anticipate a discovery which was the result of a series of gradual guesses and experiments, hereafter to be recorded. *Thales*, no doubt, believed this humour or moisture to be, as he said, the essence and principle of all things. He believed it in some sort a principle

sical Phi-
losophy.
Thales.

Moral and
Metaphy-
sical Phi-
losophy.

to which he might refer himself. But the thought which lay behind this notion, and in vain sought to compress itself into it, is the one which it really concerns us to take notice of. For thus we are able to perceive in this early philosophy a most interesting step in self-consciousness, and we obtain a valuable help towards understanding how the successive theories respecting the outward world were connected with the progress of apprehension respecting the world within.

Anaximan-
der.

Anaximander is the next in order of the Ionian philosophers, but the interval between him and Thales seems too wide to admit the notion of their being connected together as master and disciple. He was born, however, in the same city, and the speculations of his predecessor produced, we imagine, more influence upon him than some historians, observing the marked opposition between them, not only as to their outward form but as to their principle, have been willing to admit. *Anaximander* appears to have advanced in astronomical and geographical knowledge far beyond Thales; it would seem also that he was the first of the Greeks who recorded his speculations in writing. From these two circumstances we might, perhaps, have guessed that his philosophy would have acquired a new character, that the simple observations of Thales would give place to more extended observations; but that, on the other hand, the lively consciousness of what was passing within him would be lost to a great degree in the attempt to impart it through logical forms to others. Such are in fact the characteristic differences in these two early thinkers. They offer one of the simplest and most primitive illustrations of the difference between thought employed in the solution of actual difficulties, and thought employed for the construction of a theory. A fact so simple, so obvious to every child, as that every thing requires moisture for its life, appears to this observer on a large scale as pregnant with no meaning; yet seeing that an hypothesis has been suggested for explaining the facts of the universe, he too is urged to reflect, and to try if he cannot produce another more comprehensive and rational. He looks round upon the world, and sees that there are going on upon its surface millions of facts like that to which Thales attached such importance. He cannot find which of these facts is the most potent and generative, but he can at least find a name for that to which all other things owe their origin: he calls it ἀρχή, beginning. This is something; but he can do more, he can find out a name for the whole multitude of powers, principles, influences, facts that are at work in this universe; he calls it τὸ ἄπειρον, the Infinite. The person who invented such a phrase might well feel that he had reached the Hercules' pillars of philosophy. What could be said after him which he had not comprehended in his formula? We believe, however,—it is justice to *Anaximander* to believe—that there was something in his heart and mind which he himself could not comprehend in it; that this word—infinite—brought with it thoughts upon which he meditated in silence and awe, and could not express to others or to himself. The intellect which imposes upon itself words for realities, generalizations for principles, be it remembered, is still the intellect of a man; it would be falling into his own delusion to suppose that he felt no more than he could put into phrases.

Anaximander is commonly said to have made earth his centre, as Thales did water. This language, without being wholly erroneous, may easily mislead us; the earth and the water are not opposed in these two sys-

tems, as the (so called) solid element to the fluid; for we have seen that, according to Thales, water meant, not an extended separate mass, but the invisible moisture in all things. On the other hand, the earth, in *Anaximander's* mind, must have been contemplated as including both seas and land, and all the phenomena which characterise either of them. For this reason it was the natural expression of his notion of the infinite and indefinite, redeemed that notion out of the circle of mere abstractions, and formed a link between his speculations and those of his predecessors and his successors.

The doctrine of *Anaximenes*, the third philosopher of this school whose name has been preserved, exhibits a very interesting step in the progress of internal reflection. That within us which is not visible, or audible, or tangible, does not present itself to him as a mere quickening or vivifying principle; he feels it to be the ruling thing, the great controlling power which all that is visible, audible, and tangible is meant to obey. The necessity of moisture to all things is not the fact which lays hold of his imagination; still less could it be satisfied with a mere theory or index to a great number of facts. He is struck by the dominion which air exercises over all nature, how secret and invisible a power it is, yet how universally and inevitably acknowledged. The importance which he attaches to this observation is not the unconscious effect of an internal feeling; he says, plainly, that the air rules over all things, as the soul, being air, rules in man. These words which Plutarch gives us are very interesting. They strikingly indicate a period when a man is struggling to discover something in nature which answers to something in himself, and does not know which is the ground of the other. The thought of what he is himself dawned upon him while he was noticing the outward fact; that would therefore seem to him the first and most important; but again there is something in him which would not permit him to consider it the first. He must assume himself as the ground of the comparison; here there is another important advance in discovery. The philosopher is beginning to suspect that the outward object is symbolical. He has not realized the conviction, but it hovers about him and is ready for a future development. One other observation it is necessary to make respecting *Anaximenes*. The theology of Thales was by no means physico-theology: it seems scarcely to have connected itself at all with his speculations on the principles of things. He acknowledges that the gods saw the very thoughts of men, and that satisfied him. What they had to do with moisture he did not care to inquire. The logical formulas of *Anaximander* must have been far more fatal to the recognition of direct personal powers. The Infinite must have included them as well as all other things. In *Anaximenes* we discover the first attempt to combine the ideas of an elder faith with his reflections on nature. The ruling power of air, or in air, why should it not be he who in ancient times was called Jove? The thought may have caused a pious pleasure to the inquirer; it seemed to give philosophy greater fellowship with humanity. But we may find hereafter that whenever it has been reproduced, it has been equally mischievous to theology and morals, to metaphysics and physics.

The last and greatest of the Ionian school, properly so called, is *Heraclitus* of Ephesus. Of all the Greek philosophers, except Socrates, this man seems to us to possess the most marked individual character. That

sical Phi-
losophy.

Anaxi-
menes.

Moral and
Metaphysical
Philosophy.

vulgar notion of him as the crying philosopher must not be wholly discarded as if it meant nothing, or had no connection with the history of his speculations. The thoughts which come forth in his system are like fragments torn from his own personal being, and not torn from it without such effort and violence as must needs have drawn many a sigh from the sufferer. Neither is that other notion of him, as "the obscure or dark" man, an unfounded one. The fire that was in his heart and brain, and of which all the world around him presented the image, no doubt emitted much smoke which did confuse and stifle, not, perhaps, to his displeasure, the careless gazers and passers by; but there was something within him which neither his tears nor his smoke at all adequately represent. If Anaximenes discovered that he had within him a power and principle which ruled over all the acts and functions of his bodily frame, and which had no so living type as the air, Heraclitus found that there was a life within him which he could not call his own, while yet it was in the very highest sense *himself*, so that without it he would have been a poor, helpless, isolated creature—an universal life, which connected him with his fellow-men, and with the absolute source and original fountain of life. The individual life (said he) is really a life at all only so far as it has communion with this universal life; separated from that it exists indeed, but potentially, not actually. "Like as the coals which, when they come into contact with the fire by connection with a different nature from their own, become fiery, but when separated from it burn out, thus the portion from the encompassing whole, which hath taken up its tabernacle in these our bodies, by separation therefrom becomes well nigh irrational, but by the communion of natures through its various passages is made homogeneous with the universal. Now this common and Divine reason, by participation whereof we become reasonable, Heraclitus calls the criterion of truth; whence that which appeareth to all in common is the thing to be believed, for it is received by this common and Divine reason, but that which happens to any single person alone is not to be believed, for the opposite cause." Such is the profound fact which was revealed to the mind of this Ionian philosopher, and which, as the extract we have made partly shows, he saw expressed in the relations of fire to the different objects of the universe. It was inevitable that an Ionian of this age should seek in the forms of outward nature an expression for the truths of his own being. Heraclitus had no wish and no power to invent an entirely new method of speculation; nay, that which he inherited from his predecessors seems remarkably suitable and almost necessary for a mind of his character. Far more imaginative and poetical than any of them, he contemplates the outward object which symbolized the operations of his mind with a delight only the keener for being mixed with a certain under consciousness which they did not possess, that it was an image and not an archetype. All the secret workings and manifestations of fire suggested to him new thoughts and reflections which may sometimes have carried him very far from the original principle which gave occasion to the analogy. But in general we shall find that the different opinions attributed to Heraclitus by others, or which are found expressed in his own fragments, dispose themselves harmoniously enough about this centre. If there is a universal life in things which alone constitutes

them what they are, then these things looked at in themselves are visions, phantoms only; the phenomena of the universe exhibit merely an endless flux and reflux. But contemplate the meanest organized body as organized, and it acquires a meaning, a reality; it becomes a part of the universal harmony. The soul again which beholds these phenomena, what a poor paltry thing it is, a victim of delusions and impostures at every moment! Miserable creature, only to be wept over or despised! But this soul, sharing the universal life, and conversing with it, how glorious it becomes! capable of knowing the name of Jupiter, which is its only business and object.

Our philosopher was therefore almost necessarily an aristocrat, in the Greek sense of the word. For order and law (says he) we should struggle to the death; the individual powers which democracy worships are utterly contemptible. In all the utterances of Heraclitus there seems to be a singular consistency, and what we know of his life is a luminous commentary upon it. The sense of a harmony existing beneath a perpetual conflict of powers, and making that very conflict the means of their preservation, pervaded his being, gave the tone to all his thoughts, and realized itself to him in all the inner forms and outward images of nature.

These four men, THALES, ANAXIMANDER, ANAXIMENES, and HERACLITUS, seem to be clearly distinguishable from all those who have been commonly classed with them as members of the same school. They were, in the strictest sense, Ionians; they succeeded each other at no very considerable intervals, and there seems to be a connection between their opinions, which is not the less striking because it is often a connection of opposition and contrast. To find the law of his own being by meditation on the external world, this, as we suppose, was the object which each proposed to himself. On the whole, each set about the accomplishment of his object with much sincerity and singleness of aim. We cannot therefore help regarding their inquiries with a very deep and affectionate interest, or doubt that they exercised a very important influence on the Greek mind. Nor is it impossible that the thoughts and strivings of these simple and earnest men might teach something to men of a more enlightened generation, who can study the laws of nature and of mind without perceiving that they have any relation to each other, or that they themselves have any important connection with either.

Pythagorean School.

We now come to the second of the Greek schools, which had an Italian birthplace, an Ionian parent, and, in many important respects, a Dorian character. Pythagorean school.

In order to understand the peculiarities of this school and its influence upon Greece, two remarks ought to be especially borne in mind. The first is that the particular doctrines to which it gave birth are referred by the most trustworthy authorities to Pythagoreans rather than to Pythagoras. The persons whom Plato and Aristotle seem habitually to recognise as the propounders and defenders of this system, were men living at a distance from all the circumstances which acted upon their master; not Italian colonists, not members of any particular guild or corporation, but schoolmen subjected to the ordinary influences of Greek society. Our second remark is, that in spite of this practice of theirs no phrase ever escapes their lips which can lead us to sup- Pythagoras.

Moral and
Metaphysical
Philosophy.

Moral and
Metaphy-
sical Phi-
losophy.

pose that they considered Philolaus, Lysis, Eurytus, or Archytas as really entitled to the fame which the voice of all Greece assigned to Pythagoras himself. It seems to have been admitted universally, and most by the wisest men, that there was something in him which he had not transmitted to his successors, something which, whether capable of definition or not, had left a permanent impression upon the character and literature of his country.

These considerations seem to us very important helps in understanding the true nature of this philosophy. Within it we believe are certain elements of thought which came forth from the soul of a living man, and were by him communicated in their power to other men, not in digests or argumentative treatises, but in pregnant maxims, in allusions to passing objects and scenes, in explanations of difficulties as they arose, in a discipline suggested rather than imposed and practised before suggested. These thoughts are what the Greeks from age to age felt of Pythagoras; when they spoke of him they meant these; what husks of opinion formed about them afterwards, when they had been dried in the schools for use or exportation, is a question certainly not without interest, but chiefly interesting to those who have had some taste of the genuine fruit.

Pythagoras was born at Samos, in what precise year may be doubtful, certainly at a time when the Greek colonists had become conscious of a strong impulse towards philosophical inquiries. Under what master he studied has been a subject of great controversy; if we might venture to choose one guess out of many, which may all be false or all true, we should take that which assigns his early training to Anaximander. That philosopher, as we have seen, carried his mathematical studies further than any of his predecessors; his geometry in a great degree determined the nature of his theory. A youthful pupil of earnest character and high imagination coming into contact with such a thinker, would be likely to experience a great conflict of feelings. The science, new not only to himself, but in some measure to all around him, would seem to him strange, wonderful, sublime; the doctrine appended to it would repel him as cold, vague, and unsatisfactory. He would begin, we may fancy, to meditate on his teacher's favourite phrases, "the infinite—*τὸ ἀπειρον*—this forsooth is the sum of all things in the universe. A conclusion how unlike that which geometry would have suggested! that leads us to the idea of limitation, distinctness, in each thing and in all things. And is not such limitation, such distinctness, that which constitutes their perfection? Surely it is this, the *πέρας*—the ultimate limit, and not the limitless, which the wise man is to seek after.

Geometry.

Arithmetic.

Again, Anaximander talked of an *ἀρχή*. Here, indeed, he has profited by his science. Mathematics did teach him the necessity of this. He found every line starting from a point, every series beginning from a fixed number. But why forsake the teacher? Why go abroad to look for your beginning when you have it in the very instrument which you carry with you? You Ionian philosophers are groping after unity in the world about you. But where did you get that idea? Was it from their numbers, from this geometry? Surely it is there that we find not the mere shadow of unity, but unity itself." Such thoughts we may fancy began to work in the mind of Pythagoras while he was yet in Ionia, and to excite in him a discontent with previous methods of inquiry, and a hope that he might discover a better. With these feelings we may suppose him to set out on his travels,

not, however, till he has carried away another (perhaps a greater) benefit from his Asiatic education. The rhapsodists, who used to sing the legends of earlier days to the Greeks of that region in which Troy stood, and in which Homer or a number of Homers lived, these were perhaps silent. But not only their words were preserved, and by this time at least committed to enduring characters, but what was perhaps even more important, the melodies in which they had spoken still lived in the hearts of the people. The impression of the Dorian and Lydian measures on the young Greek must have been very deep; it might be effaced afterwards in some by the passion for abstract speculation, in others it would give speculation itself a richer and more poetical character. All the thoughts of Pythagoras respecting the mystery of number seem to have combined themselves from the very first with musical feelings and associations. Was not music itself an illustration, the highest illustration, of this mystery? Whence came that strange disposition of thoughts and words into verse, whence the fascination of melody and tune? whence, if number be not the secret law, the moving soul of the universe?

All these apprehensions and imaginations might have dwelt in his mind and produced little fruit, or no better fruit than a crude philosophical system. But Pythagoras, as we said, became a traveller. The reports of the regions through which he journeyed are all uncertain. This at least we may conjecture with tolerable confidence, that he was brought into contact with human beings in a variety of different positions and circumstances, and that he began to think more deeply of their nature and destiny. And then with what new interest, in what a new light, would the number-mystery present itself to him! This surely was the very problem which all legislators had been seeking to solve,—in what way a number of apparently separate units might be able to feel themselves really a unity. All society, all government was but the working out of this problem. Away then once and for ever with all Ionian experiments after a physical unity; here was the true field for examination and discovery. But what is it in man which has the capacity for association and organization? It is not resemblance in feature which produces it; it is not contiguity in space which produces it. It is that wonderful thing which inhabits this animal frame—which can transport itself beyond all limits of space and time. I, Pythagoras, can carry myself back to the age of Achilles and Agamemnon; doubtless in some condition or other I actually lived in their time. I can project myself for-wards into ages that shall come; doubtless under some condition or other I shall live in those ages. But in what condition? This soul, which can thus look before and after, can shrink and shrivel itself into an incapacity of contemplating aught but the present moment, of what depths of degeneracy it is capable! what a beast it may become! And if something lower than itself, why not something higher? And if something higher or lower, why may there not be a law accurately determining its elevations and descents? Each soul has its particular evil tastes, bringing it to the likeness of different creatures beneath itself; why may it not be under a necessity of abiding in the condition of that thing to which it has adapted and reduced itself?

Such thoughts Pythagoras may, or may not, have borrowed from Egyptian priests. Doubtless to a man in his posture of mind every old tradition, every relic

Law.

of national faith, will have been precious; still there was nothing in the doctrine of a metempsychosis which might not easily and naturally have grown out of his reflections upon that which makes men human, and enables them as human beings to associate with each other. To another and deeper discovery he was no doubt led by studying the governments of different countries, especially those which had received the Dorian impress. He found everywhere in these communities that the bond of connection was the recognition of a power superior to man, a righteous law-giving power. No human legislature ever dared to dispense with this recognition, no society could cohere without it. Deep and awful idea! The union of men presuming a still deeper ground. Is not this ground the *πέρας*, the ultimate unity, after which we are seeking?

Thus gradually we suppose the idea of limitation, which Pythagoras had acquired from geometry, and which had been brought out in his mind in opposition to the notion of an all-comprehending infinite or indefinite; and the idea of beginning and succession which he had acquired from arithmetic, and which had come out in his mind in opposition to the notion of a mere external ground of things, fused and softened as they both were by the sense of a music dwelling deep in the heart of the world, may have become associated with practical thoughts respecting the nature of the human soul, and the bonds by which souls are related to each other, and finally, with still more awful contemplations respecting the being of God.

But it followed from the very nature of these thoughts, no less than from the character of the mind in which they were formed, and from the processes by which he had arrived at them, that they could not be satisfactorily expressed in the most luminous spoken or written discourse. Pythagoras felt that his principles could only be embodied in a society of living men. In the bonds by which they were held together in their dealings with each other, and with men without; in the silence and fear with which they acknowledged an invisible ruler was his inmost meaning to be expressed. Thus would the proportions and relations of the universe be manifested on their highest ground; thus would the mystical harmony be felt and acknowledged; thus would the dignity of the human soul, its capacity for growth and perfectionment, be proved; thus would the nature of distributive justice, the geometry and arithmetic of politics be practically realized; thus would the idea of God be taken out of the cloudy formless region in which philosophers had caused it to dwell, and be felt as the foundation of social life. Such, we apprehend, was the feeling of Pythagoras; and if so, we may go a little further than Mr. Thirlwall; we may admit that the corporation or order which he established in the South of Italy is not only for the ordinary historian, but even for the historian of philosophy, a more interesting subject of contemplation than the mere details of his doctrinal scheme. Instead of feeling the difficulty which some feel to connect Pythagoras the thinker with Pythagoras the politician, we own we find it a hard matter to conceive how they should be separated. We do not know what his philosophy would mean, or how it would be generically distinguished from the Ionic on the one side and the Eleatic on the other, if it were not for this very circumstance, that Pythagoras sought for that unity in a fellowship of living persons, which the former had hoped to find by observations upon the sensible world, the latter

by investigating the demands and constitution of the mind itself. Looked at from this point of view, the speculations of Pythagoras and the practical experiments in which they terminated, seem to us full of the profoundest interest. We would entreat our readers not hastily to throw aside the consideration of them, because they are told that Pythagoras was a fantastical dreamer; that he could not distinguish a geometrical point from a numerical unit; that he talked wildly about tetrads; that he fancied himself a supernaturally inspired person; and that he pretended to give to his society the mystical and divine foundation. Let them rather consider whether there be not some fantasies and confusions in our own minds upon these apparently simple subjects, which a kind-hearted consideration of the truths which were in the heart of Pythagoras, and of the imperfect and erroneous methods of sensible exposition which they sometimes found for themselves might remove. Let us not say that he was a slave to certain idle notions about number, till we have studied the history of human thought with some attention, till we have understood how much all men (ourselves included) are subject to delusions of this nature, until we have satisfied ourselves that this was not one of the earliest efforts to escape from the delusion, instead of to perpetuate and propagate it. Before we cast any very heavy blame upon him for fancying that he might sometimes lawfully use the great gifts which had been bestowed upon him to startle men with a sense of his own dignity, rather than to instruct them in the true conditions of theirs, let us observe how constantly human vanity, under the most favourable circumstances, has been liable to this temptation; how much more it is likely to assail those who are establishing or presiding over a society, than those who live only in their studies; how far more really disgraceful and mischievous after all that habit of mind is which leads a man to look upon his wisdom and power as self-derived, as ministering only to self, than that which acknowledges the fact of communications from above, and only falls into mistakes and conceits respecting the method of them. Before we condemn Pythagoras for believing that a human community has a mystical groundwork, let us ask what other groundwork it can have, if it is not built upon the sand, and destined to instant destruction.

Eleatic School.

We have now briefly examined two of the Greek schools. We have found the Ionians seeking for unity in external nature, the Pythagoreans in the constitution of human society. We have seen how the latter was led by his speculations upon man into the recognition of a higher and more transcendent unity in God. It was this part of his philosophy which seems to have attracted the attention of *Xenophanes*. The countryman of Pythagoras in both senses, an Italian emigrant from the Ionian colonies, this remarkable man felt the influence of the thoughts which each region had generated. He felt that there was a world full of wonders lying about him, and he endeavoured in the true Ionian spirit to understand this world. But the grand truth of Pythagoras, that man wants another ground to rest upon than the world, had presented itself to him with no less irresistible evidence. There must be God as well as a world, and the world and God are not one. The passage from one of these truths to another was not, how-

losophy.

ever, bridged over by this inquirer as it had been by Pythagoras. He did not ascend from nature to those instruments by which man takes hold of nature, and from these to man himself, and from man to God. The two ultimate points of the series were at once brought into connection and contrast in his mind. There is something which I see with these eyes, hear with these ears, there is something which I do not see, or hear, or taste, but which emphatically is. That which I see, and taste, and handle is continually changing the aspects which it presents to my eye, the impression it makes on my ear or my palate. Can I affirm of this in any sense that it is? Is it anything more than that which appears, and of which the appearance yesterday can by no means be identified with the appearance to-day? Can I affirm of any thing surely that *it is* but just of this one thing of which I have no evidence, but simply this necessity of affirming it. Such are the first hints of a principle which has produced more real effect upon philosophy from that age to our own, and which in different ways has been working more secretly at the heart of all philosophy, than any of which it is possible for us to speak.

Xenophanes, when he had once made the discovery that the most real is not that of which his senses gave him information, nay that, strictly speaking, his senses gave him no information of what is real, announced the fact to the world in poems, of which we still possess some fragments; but it was not the speculative side of this discovery which most interested him. That Being whom my mind thus affirms, what is he? Into this solemn inquiry Xenophanes entered with an intelligent earnestness and freedom, and yet, in general, with an awe which inspire us with a great respect for his character. Starting from his one immovable position, that the senses give us no information about God, he began with a bold and rude, but certainly not an impious hand, to tear in pieces the fables of paganism. All the notions of the gods in Homer are connected with sensible forms and appearances; these, therefore, are essentially false and degrading. They are multitudinous, because it is from the impressions on the senses which reflect a multitude of objects, and so many phantoms of the same object, that the notion of them has been derived. And even if these appearances were not sensible, how can any conceptions of men about God be otherwise than false? Must not they be derived from themselves, or from things on a level with and lower than themselves? If an ox could worship, would he not impute to his god horns and hoofs? Away with all conceptions then. And is your Pythagorean better than any other? What do you mean by saying that God is either finite or infinite? the finite and the infinite are both alike thoughts of our own. Thus reasoned Xenophanes, full of earnest faith in the reality of that which he was, nevertheless, reducing so very near to a mere negation. He had learned a precious truth,—Man can feel a ground of being deeper than his own being; man can be certain that God is—but *what* he is? of this he could not be certain, only what he is not. In this mournful conclusion was Xenophanes obliged to rest, and it spreads a mournfulness over all that he thought, even when he is most earnest and true. For he was a real man, no mere philosopher, who can come at this same conclusion, and repose in it, because a conclusion is all that he wants, besides the glory and self-satisfaction of being the concluder; he had a heart which delighted in the truth which had

been revealed to him, and, therefore, did not delight in the miserable void into which, partly through a real love of that truth, partly through hurry and impatience of all other truth which men before him had acknowledged, he was unhappily led.

A healthier thinker than Xenophanes, yet one in whom it is not perhaps possible to feel the same interest, took up his course of inquiry; this was *Parmenides*. The question respecting the nature of God, which had so occupied the philosopher of whom we have just been speaking, does not seem at all in the same degree to have agitated him. His mind rested on the principle of Xenophanes, that what the senses present to us are appearances; that only that which the mind affirms without the aid of the senses actually is. What is this then that the mind affirms? Xenophanes had said "God." Parmenides said "Unity," or "The One." My senses tell me thousands of things, and yet has not every man who thinks and feels ever been groping after some one root and ground of all these things? This, verily, is what man wants, and this is affirmed to be by that within him which fights against apparitions and phantoms. Plurality is merely one of these apparitions, deceitful, transitory; nothing abides but unity, this is permanent, eternal. Such a belief could not dawn upon the mind of a Greek philosopher without imparting to him a feeling of deep wonder. He had seen a succession of Ionians questioning all nature to tell them of this unity. He had seen Pythagoras evoking it out of the relations of number, and actually constructing a human society to illustrate it. And now it seemed that this unity was a condition of the human mind itself—it had been seeking high and low, it had been seeking for that in all other things which really dwelt only with itself. The confused look of a child gazing upon a new world, is but a faint emblem of the surprise with which such a thought must have possessed the mind of an earnest seeker on whom it has just burst. Yet he cannot doubt that it is a true thought. It makes so much of all that had before been perplexed in his mind intelligible, it accounts so well for the thoughts which have revealed themselves to other men. But what consequences follow? Faith in the things about us becomes impossible; we live in a shadow world; we do not, in fact, behold any thing. For these distinctions of things, this apparent multitude of objects, exists not; it speaks to our fancy only. The unity which the mind beholds and demands, this only has substance.

Every one must see how this doctrine of *Parmenides* *Zeno* laid him open to the jests of witty men, such as grow upon the surface of all lands, and of which Greece and her colonies were certainly not less productive than others. These wits believed no doubt that they were opposing self-evident facts to mere dreams. But Parmenides had a friend and disciple who was not willing to leave them in undisturbed possession of this opinion. Zeno of Elea was convinced that there was not only positive falsehood, but direct absurdity in that doctrine which experience seemed so irresistibly to establish, and he boldly undertook to make this absurdity palpable to the popular mind. In a series of arguments, some of which are still preserved to us, he endeavoured to show that space cannot exist, that we cannot suppose a plurality of objects without attributing self-destructive qualities to them; that if there be a number of real existences, this number must be both finite and infinite; lastly, that the notion of movement involves a contra-

diction. Our readers would not, perhaps, be much interested in these early specimens of Greek subtlety; nay, they would be inclined to denounce them as the exploits of a mere word-conjuror. But assuredly Zeno deserves no such name. He was both in action and speculation a brave man, and we owe to him a most important practical discovery. In fact, he occupies a peculiarly important position as a thinker, which it is for the advantage of our future studies in Greek philosophy that we should understand.

Words.

Every philosophy must have an instrument or organ to work with if it would make itself intelligible. Some external object served this purpose for the Ionic philosopher; lines and number for the Pythagorean. But what was the instrument of the Eleatic philosopher? He seems to have ascended into a region of such pure metaphysic, and so entirely to have rejected all common and sensible analogies, that one does not at first see how he can ever impart his doctrine to others, or at least suggest any successful method for pursuing investigations in his own direction. And this difficulty seems to have been felt by Xenophanes, and to a certain extent by Parmenides. Precious and pregnant as are the hints which each of them present us with, it seems likely that they will be obliged to stop at the point which they have already obtained, and to leave no race of successors. But Zeno has found the solution of the puzzle; he has found that *words* bear to this philosophy the relation which sensible objects and numbers bear respectively to the other two. The language in which we discourse with each other must needs embody the law and principle of our own mental workings, and it was exactly this principle which the Eleatics were dealing with. Zeno had only an imperfect consciousness of this truth, but he acted upon it, and it bore useful fruits for him and for us. There was no falseness in his use of words. He felt that they did affirm and embody truths, and he employed them for the purpose of elucidating truths. And herein he was surely as honest as those wits who set themselves to confute Parmenides and philosophers of his class by an appeal to experience. For they too profit by our belief in words. They awaken our consciousness to the fact, that the words which we speak bear on them an impress and image of the external world; and it is this consciousness which they rest upon as their real defence against the philosophers who set at nought the evidence of the external world. Zeno awakens our consciousness to the fact, that the words which we utter express something to which there is no counterpart in the external world, and he rests upon this consciousness to oppose the conclusions of those who set at nought the witness of their own minds. Both appeals are in themselves fair, and carry conviction with them. But the one merely convinces us of a fact which we took for granted previously; the other obliges us to perceive truths lying very near our inmost being, which were yet almost entirely hidden from us.

Logic.

But it is the practical discovery which was the direct result of this search after an organ or instrument for the Parmenidean philosophy that obliges us to regard Zeno with most admiration and gratitude. Mathematical science we owe, according to the best historical evidence, to the East. And it entirely accords with the calm, contemplative, and yet sensual character of the Orientals that this should have been their contribution to human knowledge. But the science of *Logic*, the science which declares not what are conditions to which external things

are subject, but the conditions under which we ourselves speak and judge—this was of purely Greek invention. No other people had ever the subtlety to conceive the possibility of such a science, far less to ascertain its distinct province and its appointed work. Though logic, in a formal and narrow sense, is considered as the antagonist of poetry, yet only a most imaginative and poetical nation could have discovered the meaning and necessity of logic, and have given it the statue-like perfection which it has attained in Greek hands. Now Zeno is believed, on the best grounds, to be the inventor of logic. He first was led clearly to perceive that the mind has a distinct law regulating its own affirmations, and he consequently was first stimulated to inquire what this law may be. How much we owe to him from this achievement we shall understand better as we advance. Our principal object here has been to point out the connection between it and the Eleatic philosophy, of which Zeno was the accomplished and able defender; to indicate the kind of influence which that philosophy exercised upon the mind of Greece; to show how important a place it fills in the history of human inquiry; and to excite our readers' interest in the future development of the doctrine which they have beheld in its first germ. In so very rapid a sketch as ours it is clearly impossible to do more than notice what seems to us the living and central peculiarity of each system as it rises up before us. But the real germinant principle is often hard to discover amidst the multitude of mere notions and opinions with which it has environed itself. An historian will distrust his own sagacity in detecting it, and will rejoice greatly if he can find it any where in its rude and primitive shape. Little value as it may seem to have, nay, as it may actually have, while it remains in this condition, yet he deems it not wise to wait till the animalcule has become a perfect insect, or till the insect has died, before he commences his examination of it. We offer this apology for noticing the anti-Socratic schools, briefly indeed, but yet at a length which many may think disproportionate to the time that we shall be able to bestow upon their successors. We are convinced that our readers whom, as we have remarked, we wish not to furnish with a history, but to put in a right method of procuring one for themselves, will have a clear or confused understanding of the palmy period of Greek philosophy between the age of Socrates and of Aristotle, as well as of the age of senility and decrepitude which followed, exactly in proportion as they study or pass over the years of its infancy. Let them not hope to understand Plato or Aristotle, or even Epicurus, Zeno of Cittium, and Carneades, if they have begun with despising Heraclitus, Pythagoras, and Parmenides. Nay, we might go further and say, that we should greatly doubt the pretensions of any one professing to have a clear understanding of Hobbes, Locke, Leibnitz, or Kant, who could discover nothing but confusion and barrenness in these early inquiries.

The Sophists.

Hitherto our attention has been directed to the comparatively silent and solitary labours of thinking men in provinces remote from either of the two Grecian capitals. But from the conclusion of the Persian War the thought and speculation as well as the active energies of Greece had been continually seeking for themselves some centre of light and attraction. We have already observed that

sical Phi-
losophy.

The
Sophists.

the two leading tribes of Greece respectively embodied those two great qualities of the human spirit—respect for order and law; consciousness of individual powers, and a desire to exercise them. As in the speculation of particular men neither of these bore much apparent fruit till it had been acted upon by the other, so was it also to a great degree in the actions and movements of Greek society. Till Athens had produced men whose principal aim was to give her something of the order and compactness of the Lacedemonian polity, the great intellectual energies of her sons never really displayed themselves. On the other hand, till Sparta had been in some degree brought into friendly contact with Athenians, and had experienced some of the lively impulses by which they were continually actuated, it never became really conscious of its own position as the witness for the stable power and order by which these impulses are counteracted. The crisis when these two feelings and principles began to put themselves in conscious opposition to each other—that crisis in which their mutual dependence upon each other became also most apparent, and began to be most realized by thoughtful men—is the period to which we always look back as the most interesting one of Greek history. Then did Greek poetry come forth in the form which seems to have been most exactly fitted to express that feeling of an overruling system, and of a power in man to strive against it even if he must ultimately succumb, with which the Greek mind was now exercised. Then the sculptor and painter, and in a less degree the architect, was teaching his countrymen to feel that nothing which they saw could have meaning or reality if there were not a deeper meaning or more perfect truth beneath, which the highest human work fails to embody, which the very meanest proves to exist. Then, lastly, which is the point most immediately concerning our present inquiry, experiments of practical legislation and political organization began to combine themselves in a thousand strange and perplexing ways with political, moral, and metaphysical theories. The workmen in this particular branch of human labour were not poets or artists, but a race which has been known to all future ages by the name of Sophists.

It has been a very common fancy that some resemblance exists between this body and the schoolmen who appeared in Europe during the middle ages. We confess that if we were seeking for two classes of men, the most directly contrasted in all the important features of their characters, we should have selected precisely these two. That they both engaged in philosophical inquiries,—both attached considerable importance to logic—and that some members of each class took an interest in philology—and that to men living in a circle of influences entirely different from that to which either was exposed, the notions of each may appear about equally grotesque—this is undoubted. There is just enough of these superficial resemblances to make the difference in all other respects the more striking. The schoolmen of western Europe, if they ever forgot that truth was the end which they were pursuing through all labyrinths,—and this faith seems not entirely to have deserted any of them,—lost sight of their object through mere simple delight in tracing the windings of the road; the sophist of Greece disbelieved in truth altogether, and proposed to himself another object, that of exercising power over the minds of men. The error of the schoolman was, that he set too much store by all instrumental

VOL. II.

arts, as if they were precious for their own sakes. The sin of the sophist was, that he estimated every thing by its tendency to promote a low, grovelling, secular end. The great misfortune of the schoolman was that he mixed too little in human society, understood too little the actual workings of human life. The misery of the sophist was that he lived in a perpetual round of bustle and excitement, caring for no thought but so far as he was able to translate it into talk, perpetually confounding together the realms of speculation and action.

This, in fact, is the distinguishing characteristic of the sophist. He must always be talking and doing, or teaching others to talk and do. For this purpose he avails himself of all modes in which the human feeling had expressed itself in all different periods, sympathizing with none, able to convert all into an argument that man's life is merely a shifting mode, that nothing is, but every thing seems. Now he is a great mythologist; knows all that poets have imagined; has a thorough insight into the popular faith; he can tell you how this and that notion had its origin, he can adopt it into his own system, or laugh at it as he finds most convenient. Now he is a natural philosopher; the thoughts which a Thales or an Heraclitus actually worked out become part of the implements of his trade; he can bring these theories skilfully along side of the old cosmogonies, and so at his pleasure prove the ancients to have been profound naturalists, or show that all their conceptions about the divinities meant nothing. Again, he is versed in all the ideas of Pythagoras about order and society; he can parade his acquaintance with the doctrine of transmigration, or with the mysteries of the numerical scale, that men not possessed of this knowledge may feel how absurd it is for them to pretend to any perception of right or wrong. But most of all he has studied in the school of Zeno, and can tell how little the evidence of experience is worth, how little reality there is in things, what secret powers lie hid in words.

What can a man do after a king? what can a sophist hope to accomplish after these Greeks? Protagoras, Prodicus, Gorgias, Hippias, may be fairly said to have carried the trade to the furthest limits of which it is capable. They were not, as is sometimes imagined, mere pretenders to talent or erudition; they were men of more than Greek sagacity; some of them even appear to have possessed creative powers; all possessed large and various information. Whatever mere intellect without a moral meaning or purpose can do they accomplished. Nay, they may be said to have demonstrated how very much it can do, and what is the nature of its doings. They proved that it has the power to weaken the sinews of a nation, to destroy, as no wars or tumults can, its innermost heart. We should beware of despising their gifts, which were in all respects most remarkable. Nor could the possessors of them, even by the art of the most consummate genius that the world has ever seen, have been made the objects of our scorn as well as our indignation, if that consummate genius had not exhibited them side by side with a man of earnest and single aim, and compelled us to feel that true power is in *this*, and that all other powers must shrivel and look helpless when brought into collision with it.

Physical Philosophers.

Moral and
Metaphysical
Philosophy.

Universe will no doubt expect that we should assign a prominent place in this part of our sketch to the name of Democritus. In that work his theory appears as a central point in Greek philosophy. Plato and Aristotle seem to be mainly employed in illustrating or undermining it. Our excellent and learned countryman, it must be remembered, had proposed to himself a specific object, that of relieving the Cartesian philosophy from the imputation of atheism; and with a view to that object he may have exhibited the different schools in their proper proportions and relations. But when his book is taken as a manual or guide to Greek speculation generally, it cannot fail, we think, to confuse the student's judgment respecting the documents which he is to examine, greatly to exaggerate the importance of a particular class of inquiries, and to throw another and far more important class almost wholly into the shade. In a sketch of moral and metaphysical inquiries we conceive that neither Democritus nor his predecessor Anaxagoras have, strictly speaking, any title to be mentioned; we notice them both here, because they throw some light upon the character and objects of the man who was in a remarkable manner the centre of all the systems which came into being before or after his time.

Anaxagoras.

The men of whom we speak were emphatically and exclusively naturalists; the first we have met with who deserve that description. Thales, Heraclitus, Pythagoras, Zeno, started, as we have seen, with a desire to interpret their own thoughts, perceptions, powers; nature mingled itself in their investigations, but never formed the staple of them. Accordingly they were politicians, feeling the deepest interest in the social condition of their countrymen; though colonists, yet most truly and heartily Greeks. With the philosopher of Clazomenæ the case was altogether different. Living in Athens in the most stirring times of the republic, the friend and tutor of Pericles, he seems to have cared nothing for men. Life is better than annihilation, (this we are told was one of his favourite sayings,) because, while we are alive, we can contemplate the sun and the stars. The idea of a moral world, a world of affections, relations, sympathies, never presented itself to him as a reality. That of which his senses told him, was the only one in which he could believe. Not that he was merely a slave to the judgment of his senses; he was a Greek, actuated by a spirit of earnest inquiry, incapable of resting satisfied with mere surfaces and phenomena. But as he had no sympathy with the feelings and doings of men, so neither had he the intuition into the life of things which seems to wait upon that sympathy, and to be very rarely separated from it. It was not the energies and movements of the animal or vegetable world that occupied him, but merely the amalgamation of its parts. "Nothing, properly speaking, is born or dies; birth is the composition of elements, death the dissolution of them;" this was the observation of which Anaxagoras had made, and by help of which he believed that he could interpret the universe. While working out with sincere diligence the meaning of the only fact into which he had gained any insight, he threw out many valuable hints respecting the laws of cohesion and affinity, and the doctrine of a vacuum, for which later science has willingly confessed its obligations to him. It must be owned also that he did not refuse to acknowledge another principle different from the one with which he started, when he found that the problem of the world could not be solved without it. Little as he seemed to

value his position in the city of political wisdom, he could not help seeing how intellect was there every day asserting its dominion over the elements of matter. A similar power he was obliged to own, a power different in kind from the atoms of which the world is composed; a mind, an intelligence must have given them their first impulse and order. Whether this were its last and only work, or whether it ever after mingled with, and sustained, and regulated the force which it had communicated to these atoms, or which they gained from their union with each other, on this point Anaxagoras expressed himself indistinctly and inconsistently. It would be most unjust to blame him for his confusion, far rather we ought to hail it as an evidence of his honesty in recognising facts whether he could adjust them to his theory or no. It is quite another question whether we can acknowledge him for a martyr, because he was imprisoned as an atheist, and afterwards banished to Lampsacus. That the charge was formally false we cheerfully admit. One who refers the origin of the world to a mind cannot be an atheist. Let it also be admitted that such a man may connect much deeper thoughts with his speculation than we can at all measure or conjecture. But to all intents and purposes, so far as the Athenians were concerned, the accusation was true. The gods whom they worshipped were gods related to themselves, superintending their hearths and their city, their helpers, judges, lords. To substitute for such beings a mere *opifex mundi* was to introduce all the practical consequences of atheism, to rob them of a precious truth, a truth which they felt to be, and which *was*, the stability of the state and of the life of each man in it. If we confound this crime with that which was committed many years after against Socrates, we must confound two men whose feelings and objects were as nearly as possible the direct antipodes of each other. We may grant that the sublime physical conceptions of Anaxagoras assisted in forming the mind and the eloquence of the greatest statesman of Athens; but let it never be conceded that his persecution bore the slightest resemblance to that of her greatest moral teacher.

The atmosphere of Athens had, as we have seen, an unacknowledged influence upon the mind of Anaxagoras. From this influence Democritus was entirely removed. Though he visited many lands merely as a traveller and observer, he seems never even for a moment to have shared in any of the feelings and practical interests of the period in which he lived. The desire of offspring and the love of country, said this Thracian, are evil passions; they prevent us from feeling that our home and nation is the world. From this flight of cosmopolitism we may easily conclude that Democritus, if he had energy to become a speculator at all, would travel in the same road with Anaxagoras, and would proceed further in it than he ever did. This was actually the case. The feeling of Anaxagoras, that decomposition and composition are the only laws of the universe, pervaded his mind. The notion of a moving power or intelligence, not being suggested to him by any thing in his daily life, took no hold of it. But to supply the void which the want of that thought left, he attached a kind of vague and awful meaning to space. In place of the affinities and cohesions of his master he conceived that the atoms move in a vast void, and that herein is the true essence or origin of things. Democritus, the prince of materialists, had a kind of mysticism of his own. He used the phrases of the Eleatics;

Moral and
Metaphysical
Philosophy.

Democritus.

Moral and
Metaphy-
sical Phi-
losophy.

he talked of an eternal truth and of the ideas of things. But the eternal, invisible truth, which he perceived was *space*, his ideas were the infinite atoms which are and have been for ever circulating in it. We shall be compelled to notice this theory again when we speak of Epicurus and of the noble Roman poem in which it is worked out. Properly speaking, the illustration and history of it, as well as of that high form of dynamical philosophy which was contained in the poems of Empedocles of Agrigentum, belong to the student of physics. It is interesting to us as one of the many forms of opinion which were acting upon the Greek intellect, not directly, but in combination with the practical speculations of the sophist.

Socrates.

Athens
during the
Peloponne-
sian War.

Thucydides does not once interrupt the stately march of his narrative to notice the theoretical disputes of the period of which he wrote. Perhaps the modesty which is so beautiful a characteristic of his mind withheld him from touching upon a topic foreign to the habits and feelings of a soldier. Perhaps he was secretly conscious that his facts, his speeches, and his quiet reflections would really throw more light upon it than many laboured disquisitions. One circumstance must have struck all his readers—that if other historians record instances of crime as great as any that appear in his pages, no one exhibits to us so many self-conscious, self-justifying criminals. Evidently this peculiarity is not to be accounted for by the temper or talents of the historian; Thucydides is not an ambitious, professional analyst of motives like Tacitus; he would not have introduced men explaining their evil acts and reducing them to principles, if he could, by any other means, have given a faithful picture of the time. Another peculiarity of the Greek mind, at this crisis, may be seen in the very surface of his history. Whatever might be the alleged causes of the Peloponnesian war, whatever tribe jealousies may have fomented it, the people of Greece were divided from each other on a theory or a principle. Aristocracy and democracy were, more than Sparta and Athens, the watchwords of the combatants; these abstractions were, to young Athenians especially, in place of the love of soil and country which had achieved such wonders at Marathon and Plataea. Such facts prove that the mind of the nation was sophisticated.

Aristo-
phanes.

Against this evil condition of society few powerful influences seem to have been at work. By far the most efficient it would appear was the comic poet Aristophanes. This remarkable man, uniting the genius and poetical spirit which generally belong to an earlier and more unconscious age with the distinct purpose and worldly observation of a later one, had set himself steadfastly to the work of making the new revolutionized Athens look ridiculous in its own eyes. No statesman, warrior, poet, philosopher, who, as he thought, was lending his hand towards the destruction of old notions and customs, or towards the cultivation of the fashionable tone of thought and feeling, escaped his vigilance. Mob flatterers and worshippers of all kinds, but most of all those who flattered it with appeals to its too acute understanding, he regarded as abominations to whom the lover of his country should grant no quarter. That satire would be the most powerful instrument for working upon the feeling of Athenians; that wretches who had learned to laugh down all grave admonitions would ill abide

laughter far keener than their own, were at least plausible conclusions. We must not therefore hastily conclude that he was wanting in strong moral indignation against crimes which he would appear only to treat as ridiculous; still less that his affectionate feeling for the past and his sound political doctrines were merely the fruits of his discontent with particular men of his day, and not rather the causes of it.

Yet neither reason nor evidence warrant us in believing that the success of Aristophanes was proportioned to his zeal or to his genius. He may have abated some of the nuisances which were infesting Athens. He may have diminished the race of sycophants, have made the vulgar kinds of mob-persuasion less effectual, have even done something to abate the litigious spirit of his fellow-citizens. But he can have helped very little to root out that which he felt to be the real cancer of the nation's being, that which fed upon the hearts not of the worst but of the best and noblest and most promising of the Athenian youth. No one could apply any sound remedy to this evil who merely despised the age into which he was born and mourned over one that was departed, who merely saw the effects of the sophistical poison, without understanding its nature and the constitutions on which it was working. He only could hope really to reform the young men of Athens who could heartily and affectionately sympathize with them, who did not merely express his contempt or indignation for their favourite teachers, but who was ready to follow them through all their windings and subtleties, who, without for a moment forgetting the great purpose of leading them back to realities, could yet grapple fearlessly with the most shadowy and impalpable abstractions. A man of this kind would have great and sore difficulties to encounter, through which nothing but the clear perception of his object could possibly lead him unhurt. His inward conflicts, before he could be fitted for his task, must be severe; of his outward, the greatest perhaps would be this, that his purpose would be infallibly misconstrued by those who were aiming, with very different instruments indeed, to resist the same evils. It would be perfectly inevitable that he would pass with them for one, perhaps the subtlest and most mischievous, of the sophistical class. Because he sought to make men feel that there was no resting place in any of their theories or opinions, he would be suspected of universal scepticism; because he led them to feel that even they were not without a ground to stand upon, if they would seek for it, he would be accused of undermining the ground on which their forefathers stood; because he endeavoured to look through the clouds which had been drawn up from the earth, into the serene heaven that lay behind them, it would be fancied that he wished to make these clouds his permanent habitation, that he invoked their protection and did them homage.

Such a man was Socrates, and this was his fate. He was hated by sophists, and ridiculed as the worst of them. He treated the diseases of his country according to a method exactly the opposite of that which Aristophanes adopted, and therefore he was denounced by Aristophanes as the great promoter of them. We have now to consider what his method was, how it affected his own age, and what traces it has left of itself for subsequent generations.

Socrates was the son of a statuary and a midwife. He was born in a little burgh of Attica. When he came to Athens we know not with any exactness; probably

losophy.

Education
of Socrates.

about the commencement of the Peloponnesian war, when Pericles was still living and Anaxagoras teaching. That he frequented the school of the latter has often been asserted, and is at all events no improbable surmise. Nor is it at all unlikely that he may have entered with considerable ardour into the studies of his master, and may have carried away from him many valuable hints respecting mathematical and physical science. But no one who considers his character as it is presented to us in the writings of either of his disciples, or even in the play of his great satirist, can doubt that even from the first he must have looked upon these acquirements as subsidiary to another and higher design. The main effect of all physical speculations upon his mind was, it would seem, to awaken the inquiry, "What are all these to me? Let atoms be connected by what law of affinity they will, let them whirl at random through space or be guided by a directing intelligence, still this question remains, What am I?" We have traced the rise of such a thought in the mind of a Jewish sage who was destined to be the deliverer and lawgiver of his people, and to hear from a divine voice a direct answer to his inquiry. What a reality and meaning does it give to that history and that revelation to find the same feeling awakened under circumstances so different in a person not partaking the blessings of a divine covenant, though happily not removed beyond the reach of a divine influence! Not in a lonely desert, but in a crowded city; not to the member of a rude tribe, but to a man dwelling among the most intellectual of all people at the moment when their civilization had reached its highest pitch; not to one led by exile and want of other sympathy into meditations upon his human and domestic relations, but to one who was estranged from them, as well by the condition of society around him as by his own peculiar position, did this wonderful thought present itself. In the midst of the gossip of the Agora and the bustle of the Piræus, where every person had to tell of some new speculation, or was preparing for some new enterprise, amidst crowds who were rushing to the popular assembly, or the judgment-house, or the theatre, did this man begin earnestly and with his whole soul to dwell upon the thought that he himself was something, and that to know what he was was more important to him than to know ought else that man could teach him.

His
Demon.

This question Socrates was led to ask himself, and let it not be thought that it was one to which he gained no reply. The deep and satisfying answer, indeed, was wanting, but he learned a lesson which, whether the language in which he expressed it were correct or not, was in itself most true, and proved its truth in his life. He found that he had a companion and teacher within him reproving him when he had erred, warning him of evils about to be done, approving, censuring, judging his thoughts, and words, and deeds. Xenophon asks, with plain, soldier-like honesty, whether his accusers could really believe that he told a lie about this matter; and hints that it would shake his faith in all reality to suppose that a false impression on the mind of a man so clear-sighted and free from superstition could produce the effects which he himself had witnessed. We frankly own that in this XIXth Century after Christ we are just as unable to disbelieve in the Demon of Socrates as his own disciple was. Any notion of a particular impression appertaining to him, of which all men may not be partakers, we should of course reject; nor does there

appear any clear proof that Socrates himself claimed any such privilege. When he spoke of his Demon, he was asserting the fact of a conscience—asserting it not as a name or a notion, but as an actual reality, and asserting it in language perhaps more honest and less contradictory than those are wont to use who describe it *merely* as a faculty belonging to the person on whose conduct it pronounces so absolute a verdict.

That Socrates, however he may have sometimes expressed himself, did not really mean to describe this as a special gift vouchsafed to himself, we gather from the simple fact, that the whole labour of his life was to interest others in that inquiry which had led him to his first apprehension of it. What charms he used to draw a circle about him whose thoughts he could lead in this or any other direction might seem at first inexplicable. Most of the sophists were men advanced in age and reputation when he first appeared in Athens. They promised to fit men for being politicians, orators, generals, and offered very plausible evidence to prove that they could do what they professed. He promised nothing. He was come, he said, to exercise his mother's profession on behalf of those who had thoughts of which they wished to be delivered. You could not understand what line he took; whether he was a philologist like Prodicus, or a professor of statesmanship like Protagoras; he seemed to be all things by turns, and nothing definitively or constantly. Personal gracefulness and beauty were great recommendations among the Athenians; he had large projecting eyes like those of a bull, a flattened and upturned nose, a protuberant stomach; he wore a tattered cloak, and was seldom seen with sandals. Nevertheless, the youth of Athens began to flock about him; even noble young men believed that he had something to teach them, and that by some means or other he would be able to impart to them the art of governing better than the more regular doctors. It is impossible to say that some of the causes which we have mentioned as likely to alienate his countrymen may not themselves have contributed to this result. The Athenians liked a humorist, and a humorist Socrates, by his outward negligences, as well as by the whole tone of his discourse, showed himself to be. Moreover he had a most hearty genial way of interesting himself in whatever interested those with whom he was mixing; as little of solemn quackery as was ever found in the composition of any man. Add to this that he was a thorough, genuine Greek; Greek in all the habits of his mind, Greek in his taste for society, Greek in wit and argument, Greek in a brave unflinching love for his own land, Greek in making freedom (to a much greater degree than is usually observed or acknowledged) the passion and end of his life. But all these circumstances together could not have availed to counteract the many disadvantages under which he laboured, if he had not possessed the real magnet which must draw the hearts of young men after it, be they never so reluctant, a knowledge of the thing which they are really wanting, and which they have been toiling in vain to find.

Political power was, as we have seen, the one prize which the sophists proposed to themselves and held out to their pupils as the reward of all the trouble which they bestowed upon abstract speculations. Now, though there were different roads to this end, and though each teacher believed himself, and induced his disciples to believe, that his was the shortest, yet one method was common to them all; all sought to acquire power by

means of words. The mastery over words was the great art which the Athenian youth was to cultivate; his own feelings, and an observation of what was passing every day in his city, told him that there was a charm and fascination in these which the physical force of an Oriental tyrant might vainly try to compete with. It seems to have been the first observation of Socrates when he began earnestly to meditate on the condition of his countrymen, that in this case, as in most others, the tyrants were slaves, that those who wished to rule the world by the help of words were themselves in the most ignominious bondage to words. The wish to break this spell seems to have taken strong possession of his mind. But the wish would have been ineffectual, and would only have interfered with the main feeling of his life, if he had not been able to connect the study of words with that deep question respecting his own being of which we spoke just now. As he reflected, he began more and more clearly to perceive that words, besides being the instruments by which we govern others, are means by which we may become acquainted with ourselves. In trying really to understand a word, to find out what was the *bonâ fide* meaning which he himself gave to it, he found that he gained more insight into his own ignorance, and at the same time that he acquired more real knowledge than by all other studies together. In this work he knew that he was really honest, he was feeling for a ground, he was breaking through a thousand trickeries and self-deceptions. If then he was to deliver his countrymen from that miserable shallowness into which they had been betrayed by the ambition of wisdom and depth,—if he was to lead them out of the multitude of systems about morality into any firm feeling that there was a morality,—above all, if he were to rescue them from the worship of power,—this must be his means. He must not stop to canvass the wisdom of this proposition or that. He must not denounce with great moral indignation some that struck him as very mischievous or outrageous. He must not candidly and generously concede the truth and wisdom of those which seemed to him plausible or reasonable. But in every case he must lead his disciples to inquire what they actually meant by the words of the propositions which they were using, and must consider no time wasted which they honestly spent in this labour; no perplexities or contradictions dangerous which started out of their own minds in the course of it. No doubt this would be a most irritating, vexatious course of proceeding. No doubt an opponent who had adopted a certain proposition, and was provided with abundance of arguments in defence of it, would be tortured beyond measure by finding himself not fairly encountered upon those arguments, but led back into a question which he had assumed, forced to give an account of a word which he fancied every one was agreed upon, and not permitted after all to bring any of his own resources into play. It was most perplexing for a disciple who had come expecting that a certain doctrine would be either established or refuted, and, perhaps, that the ingenious arguments on both sides of the question might serve his purpose in a popular assembly, to find that he got no decision either way, and moreover that he himself had been talking all his life in a language which he did not understand, and using words as if they were algebraic characters. But yet in some way or other the sophist was taught that he was in the presence of one stronger than himself. He might chafe and fret, and

complain that he had been treated with great unfairness. But he could not say that his opponent had not got the better of him in his own word fighting; he could not say that all the scepticism which he had brought into play against the common thoughts and feelings of his countrymen and of mankind had not been made to tell with tenfold force upon himself; he could not help owning and feeling that there was one in conflict with him who had some other end than the mere exercise or display of power, and yet who did possess a power before which his own quailed. On the other hand, the disciple, amidst all his bewilderment, will have gone away with a feeling that he (perhaps for the first time in his life) had actually learned something, and with a conviction that if there be not something better than the attainment of dominion over other men's minds, there is at least a most important and indispensable preliminary to it, unless we would have our own the sport of every deceiver.

The infinite humour and vivacity of Socrates must of course have been of the greatest service in such dialogues as these. But oftentimes his opponents will have fancied that he was merely indulging his humour when he was in fact following out his principle. The practice of confessing his uncertainty or his ignorance upon any subject that was presented to him, which formed in their eyes the chief element of his "irony," was not always or generally affected. We make no doubt that he often entered upon a discussion without knowing whither it would lead, actually, as he professed, hoping to be a learner by the result of it. He was certain not of a particular conclusion, but that his method was a sound one, and that it would conduct each person who followed it to clearness and truth. It is probable that his discoveries respecting himself and his fellow-creatures were the practical fruits of this method. For instance it was by repeated experiments that he convinced himself of the immense importance of the habit of recollection; how the mind that wants it is at the mercy of all accidents; how the mind that possesses it is continually realizing its own possessions, receiving them as if they were then for the first time bestowed. Upon this principle the greatest part of his moral discipline depended. The necessity of removing the impediments to recollection, of leading the mind away from mere sensible images and impressions into an examination of its own treasures, was the purpose and ground of it. But this principle was redeemed from any Brahminical tendency by his constant use of words and sensible images as the means whereby a man feels his way into the principles and grounds of his being. It is in trying to understand all common things, what the carpenter does with his wood, the shoemaker with his leather, the mason with his stones, it is by really getting to know what we mean when we talk of all these things, that a man learns to understand himself. It is not therefore an escape from common life, from daily business, that the withdrawal or recollection of Socrates pointed at. It is the habit of seeking out in every thing that which it really is, and not merely its shapes, and appearances, and accidents, which the man is to cultivate, and which is ultimately to fit him for perceiving that which is deepest and truest in himself. Now it is the faith attained by repeated proofs and trials that man has that in him which does desire to find out the truth of things; and again that he has an inclination to be constantly conversing with the mere images of things, and that

just so far as the first of these tendencies is kept uppermost, and subordinates the other to it, he is in his honest sound position, and that just so far as the lower tendency is uppermost, he becomes a mere shadow-pursuer and shadow-fighter, which is the soul of Socrates's doctrine. It was not adopted as a scheme to supplant any other scheme; he stumbled upon it as a fact which he could no more gainsay than any one for which he had the evidence of his senses, a fact which *was*, let it be explained as it would, and must be recognised in all our dealings with ourselves or with other men. Hence followed the principle which undermined all the sophistical conclusions,—there is a right and there is a wrong. You want to know who invented these distinctions. You want to know what the worth of all the old maxims, laws, religions is which assume them. You say that they must have been invented some time or other by the strongest or the cunningest, and that what the strong and the cunning invented once they can now pull down. I answer you, man *is* something, and to be that which he *is*, is right, and not to be that which he *is*, is wrong. Most men are living as if they were something else than they are; it is the business of the wise man to know what he is, and by all means to seek to be that and nothing else. That which is crooked then cannot be made straight. To perceive, not to create, to walk in a line, not to devise one, is our business. From this statement it will be seen in what sense knowledge seemed to Socrates the basis of morality. Those who suppose that he meant to exalt the human faculties and to make them the grounds of virtue and of truth, do not merely mistake, but invert his meaning. To destroy the worship of power, and especially of intellectual power, may be said to have been the purpose of his life. And in nothing did he show this more than in his doctrine respecting the relation of knowledge to morality. As the outward eye sees certain objects, and is good for nothing except as it sees them, so the inward eye perceives certain objects and is good for nothing except as it sees them. The objects are there. It is the whole blessing of the man to behold them, as he beholds them he is like them, but they *are*—not the variable functions of his mind, but the eternal, unchangeable principles and grounds of it. A notice of Socrates is only an occasion for indicating this faith; in speaking of his great disciple, we must strive to expound it. But it is necessary to show that his whole philosophy proceeds upon the recognition of something which it does not give, and consequently drives us to those ancient laws, to that faith and reverence which Aristophanes accused him of subverting. It is pleasant to compare the actual effects of the methods adopted by the philosopher and by the satirist in reference to this very point. The comedian, anxious to preserve respect for the mythology and the notions of his fathers generally, did nevertheless, because his mind never rose above the familiar irreverent level of Greek Pagan feeling, take such liberties with the gods of his country as must have tended to lower them still further in the estimation of a sceptical age. The moral teacher, feeling the want of a communication from heaven to meet the wants and demands of which the mind by self-inquiry becomes conscious, listened with deep attention to all the ancient traditions of Greece, and probably of other lands, professed his disregard of all attempts to explain them into mere natural theories; never pretended that he had discovered any truths which had superseded them or even

made practical attention to them on his own part needless; never permitted himself to spend any of his overflowing humour (a humour not inferior to that of Aristophanes himself) upon them; never condemned any of them, except when he felt that they robbed the objects of fellowship and worship of the awe and sympathy which was their due, when the imitation of their characters would have made his own dishonourable and base. Even then it was not the faith of his country so much as the Homeric representations of it which he censured.

This view of the character of Socrates will seem unsatisfactory to those who have been in the habit of imputing it to him, either as a merit or a crime, that he set himself in opposition to the steadfast and deliberative faith of his countrymen. It is a notion less prevalent indeed in these days than it was formerly, but not yet obsolete, nor always we think supplanted (when it has been abandoned) by a truer opinion, that Socrates proclaimed the doctrine of monotheism, and died a martyr for it. The supporters of this hypothesis find infinite difficulties to overcome in the records of Plato and Xenophon, and are obliged to acknowledge either that the story has been perverted by cowardice, or that their hero was guilty of unaccountable inconsistencies. In the remarks which we have made respecting Anaxagoras, we have indicated our feeling upon this subject. We do not think that a mere negative monotheist, a mere denier of Pagan stories and traditions, would be worthy of the esteem which Socrates by nearly every part of his conduct extorts from us. The glory of unbelief belongs to Democritus, to Protagoras, to Epicurus. Some notion of a divinity still hung about all these; if the not acknowledgment of many gods be the same with the recognition of one, they are the great witnesses for truth in Greece. But if to seek after God with the continual desire of fresh light, yet with a determination to abandon none that he had,—if the continual asking for a Being of purity and truth, in whom his spirit might rest, rather than the violent rejection of any of the fragmentary notions of such a Being which might be scattered among the forms of ancient Paganism,—if even a feeling that he had no right to dispense with the aids of ancient worship, except so far as his conscience told him that they must proceed from falsehood, because they led to immorality,—if these be the feelings which would have endeared a man, placed as he was, to a Jewish sage, then none of the praise bestowed upon Socrates, though it may often have taken a wrong form, has been misapplied or exaggerated. A Christian has no occasion to fear that in doing honour to him, he is dishonouring revelation or setting up some miserable substitute for it. Other philosophies may affect to be a provision for all the wants of humanity, that of Socrates is expressly a discovery of the want, and a cry to heaven for the satisfaction of it.

As it is the internal life of Socrates with which we are chiefly concerned, we must not dwell on any of the well-known circumstances of his outward history. Undoubtedly Athens has a right to plead in mitigation of her guilt towards him the fact that his name was associated with those of the two citizens who, by two opposite lines of policy, had wrought her the greatest mischief—Alcibiades and Critias. It cannot be denied that this circumstance may have unconsciously had weight with men not habitually indifferent to justice, and that the abundant evidence which proves to us that Socrates had

done his utmost to prevent the genius of the unhappy victim of mob popularity from proving his own and his country's ruin, and had incurred the bitter animosity of the tyrant, may not have availed to remove the prejudice in his own day. But after all fair allowance for this bias, it is impossible not to believe that young men, who knew that he had restrained them from corruptions to which they surrendered themselves when his influence was withdrawn, were the great abettors of the charge that he corrupted the youth; that men who dreaded and hated the notion of an ever-present conscience, were those who eagerly voted him guilty of introducing new demons; and that those who convicted him of not honouring the gods whom the city honoured, were inwardly conscious that they honoured no gods at all. The crime showed how little that national liberty, which the Athenians had just recovered, could avail without the higher liberty of which Socrates had spoken; it excused, though it could not warrant, the despair to which some of his disciples yielded respecting the condition of their countrymen; it has proved to all subsequent generations that every really honest and wise man, even if he has not the highest and most offensive wisdom, must in general choose between the indifference and the hatred of those for whose sake he has lived.

The
Socrates of
the *Clouds*.

The hints which we have thrown out may, we think, enable our readers to reconcile the three documents which we possess concerning the life of Socrates. If we look first at the Aristophanic portrait, we shall find that it is indeed a broad and extravagant caricature, but still drawn by a consummate artist who, even in distorting the expression of his original, shows that he had studied it. We could not consistently bestow this praise upon him if he had, as some of his commentators pretend, represented Socrates as a natural philosopher. But the name of the play of which he is the hero is really almost the only excuse for such a notion. And who that knows anything of the genius of Aristophanes, or of the delicacy of the Athenian taste, will suspect him of perpetrating, or his audience of tolerating, the wretched conceit that a man worships the clouds, because he is fond of gazing at the stars? Far rather are the airy nymphs whom the philosopher is said to have substituted for the gods of his country, the patronesses of those attempts to catch the thin, delicate, evanescent meanings and shadows of the meanings of words which might so plausibly be imputed to one who estimated philology highly for its own sake, and found it so indispensable a weapon in his warfare with the sophists. The basket too in which the philosopher is found hanging between heaven and earth, because he wishes to mingle his thoughts with the congenial air, indicates no sort of apprehension on the part of the poet that Socrates looked upon himself as a mere particle of the general life of the world, and desired to be reunited with his native element; (thoughts which would have very well become Anaxagoras;) but on the contrary, points to that doctrine of the withdrawal and disengagement of the spirit from the appearances and phantasms of the world, which we have spoken of as forming so capital an article in the moral creed of Socrates, and of which his idea respecting the condition of the soul after death is only the expansion and fulfilment. The maps and geometrical instruments which the old Athenian found in the phrontisterium partly prove that illustrations from subjects with which the education of the Athenian youth made them familiar, were frequently in the

philosopher's mouth, and partly seem intended as a joke at the Socratic attempt to reduce morality to a science. The dialogue respecting the cause of thunder is evidently intended far more as a caricature of the philosopher's method of discourse than as an exposition of any of his particular opinions; the chief object being to leave an impression on the hearer's mind that Socrates substituted some special demon of his own (which the poet, to keep his metaphors consistent, and to strike an oblique blow at the really physical speculators, calls *Διων*) for Jupiter. It is necessary to make these remarks in justification of Aristophanes, for if in these parts of his play he has wished to represent Socrates as a naturalist, the whole plot of it is absurd and inappropriate. Why should Strepsiades go to a natural philosopher that he may learn how to cheat his creditors? or how should such a teacher give Pheidippides lessons in beating his father? But the most remarkable feature in the whole play, the contest between the just and the unjust principle,—this is at once decisive as to the meaning of Aristophanes, and shows us how conspicuous a place the truth of a conflict within us between a power of good and of evil, an uplooking and a downlooking mind, must have held in all the discourses of Socrates. It is this truth of which his ingenious satirist has laid hold, and which, with the quick, intuitive discernment which might be expected from an Athenian, and such an Athenian, he has perceived to be the most characteristic and important peculiarity of the system he was ridiculing.

The one point in the life of Socrates of which Aristophanes shows himself to have been utterly ignorant is, the object of it, and this is the one point upon which *Xenophon* is anxious to give us information. This worthy disciple is too much upon the stilts, he is too anxious to show us Socrates in his dignity, and therefore we miss the hearty humorist, who may be seen, though disguised, in the comedian's picture. It was natural that a soldier should be more struck with the positive conclusions at which Socrates arrived upon direct practical matters, than with his method of arriving at them. It was equally natural that the professed apologist should be eager to exhibit his master in the way that would be most intelligible to plain persons, who had been puzzled with reports of his strange argumentations, and who had fancied that some great mischief must lurk in them. But if we bear these facts in mind, and look upon *Xenophon* as rather the expounder of the Socratic discipline than of the man himself, or of his principles, we shall probably be much more struck with the agreements than with the differences between him and the other biographers. Constant homage to an invisible guide and teacher, the distinction between the principle in man that looks upward and that which gravitates to the earth, the recognition of all restraints upon the animal nature as means for the enfranchisement of the true man, we shall find in every page of the *Memorabilia* as the actuating convictions of the philosopher's life. Standing alone, *Xenophon* would be unsatisfactory, nay, even misleading. His Socrates would be almost as much a mere bundle of fine qualities or true opinions, as his *Cyrus*. But he is most useful in giving clearness and steadiness to the apprehensions which we derive from other, and, on the whole, better sources. We see clearly in him that Socrates did from first to last keep a moral end before him. We see that he was, to all intents and purposes, a practical man.

losophy.

The
Platonic
Socrates.

And this discovery, instead of making it more difficult to interpret those accounts of him which some think inconsistent with it, really makes those accounts more intelligible and more consistent with themselves, than we should otherwise have thought them.

In the Socrates of PLATO we find both the Aristophanic and the Xenophontic Socrates the mere humorist and debater, and the mere moralist, uniting to form the real man. It has often been said that the brilliant imagination of this philosopher created a hero between whom and the actual Socrates there were, perhaps, very few points of resemblance. Certainly it would be a hopeless task to vindicate Plato from the charge of a brilliant, and more than a brilliant, imagination. But two meanings may be given to this word. If it signifies a contempt of reason and probability, the gift, we apprehend, must belong in a much lower degree to Plato than to those who conceive it possible for a person living in the very city wherein Socrates had been for years walking and talking, to have palmed upon his countrymen a false or fantastic image of him. If, on the contrary, by imagination we understand the power of giving to that which would be otherwise a mere shadow, substance and life, it must surely be a most serviceable ally to him who would collect and harmonize the remembrances of an actual character no less than to him who would call into being one that never existed. Strong affection may supersede the necessity of such a faculty in a mere biographer, or rather, perhaps, may awaken it. But one who has not only to describe the thoughts, words, and acts of a friend, but to show how they bore upon the state of his country, and how they will bear upon men's speculations and lives for ages to come, has need that no ordinary measure of this faculty should be imparted to him. Now this is the work of Plato. It was Socrates, as the guide into a particular line and course of thought, that he proposed to exhibit. But in order to do this, it was absolutely necessary that he should be brought livingly before us, that we should see not his opinions, but himself; that we should be able to trace the workings of his mind, to see how he acted upon others and they upon him. By any other means Plato would have been unable to give us the true Socrates, and without presenting us the true Socrates, he could never have brought out with any clearness and distinctness the different sides of his own philosophy.

Influence of Socrates upon the subsequent Developments of Greek Philosophy.

Practical
character
of the
Socratic
philosophy.

But there are prejudices upon this subject which will not be overcome, even if we should succeed in persuading our readers that the Platonic dialogues contain a faithful picture of Socrates himself. The question will still be asked, Is the Platonic *system* the work of the master or the disciple? And it will not be answered by the obvious remark, that the seed of a doctrine may be sown by one thinker, and may only fructify in the speculations of another. For it is the old notion that Socrates brought philosophy from the clouds to dwell with men, and it is the equally common notion that Plato carried philosophy into a more fantastic region than it had ever sought for itself before. The one is regarded as characteristically the teacher of practical wisdom, the other as characteristically the idealist. What relations can

have existed between men so opposed in their objects, and in the habits of their minds?

Some writers, we have seen already, have found it possible to escape from this difficulty by denying that the traditional phrase respecting Socrates has any propriety. Instead of bringing philosophy from the clouds, they agree with Aristophanes that he made them its ordinary habitation; his grand object was to mystify his hearers; to the old disputes respecting the origin of things, the dignity of number, the perception of unity, he added a host of new puzzles of purely native invention. Such a person, therefore, might well be the parent of the ideal philosophy; it was but a consistent form of folly created out of the primeval nonsense to which Socrates had contributed the most important, that is to say, the most absurd, elements. From all the advantages of this explanation, however, and from the popularity which always attends the impugnors of an established reputation, we have effectually excluded ourselves by our previous remarks. We have admitted the truth of the notion which for so many ages has been current; we have endeavoured to show that Socrates did bring his philosophy to bear upon the actual condition of society, and that it had a substantiality to which none that preceded could make any pretensions. If the liveliest interest in the commonest, the most mundane transactions of his fellow-creatures,—if intercourse the most familiar with all classes, high and low,—if courage displayed, not in word fighting, but in actual battles with swords and spears,—if the pursuit of a direct practical end,—entitle a man to be considered something better than a dreamer, Socrates abundantly vindicated himself from that disgrace.

But were his inquiries then less deep or less mysterious than those which had occupied the schools of Asia or of Italy? We believe not. We believe that they were more human and practical, and *therefore* more deep and mysterious. Hitherto the questions which had engaged the students of Greece had related to the powers of man. Thales and his successors had questioned nature to tell him what they were; Pythagoras had studied their workings and combinations in human society. Parmenides had discovered that they have a wonderful region of their own, apart from nature, apart from fellowship. Then came the Sophists amalgamating all these doctrines; adding nothing to the knowledge of man's powers, or of the conditions under which they exist, but converting them into objects of worship, and into instruments for destroying all the faith and order of the world. This is evidently a crisis in our history. Philosophy was setting itself up against all that is dearest and most sacred to man; this any ordinary observer could discover. Socrates was permitted to see that it was also compassing its own destruction, that the idolaters of man's spiritual powers were making the exercise of those powers impossible. Philosophy, or inquiry, presumes that something *is*; the Sophists of that age, as of every subsequent age, taught that the thoughts and powers of men *originated* that which they took an account of. Laws, virtue, gods were all their offspring. Then, said Socrates, philosophy is a lie, the powers of man are a lie, and you who are worshipping these powers are worshipping a lie. For in the very constitution of these powers that is assumed to exist, which you affirm them to have created; we are only thinking beings in so far forth as we acknowledge objects of thought which preceded and are distinct from the thought itself. We

sical Phi-
losophy.

repeat these assertions, because it depends entirely upon our understanding them whether we understand Socrates, whether we see the connection between him and his great disciple, nay, whether we are able to take one firm step in manly investigation ourselves. Socrates then was the person who was destined to perform the task which we prophesied must at some time or other be performed, of connecting metaphysical with moral inquiries; of proving that a man, in order to understand his powers, must understand his position, in order to exercise his thoughts rightly upon nature or upon the relations of society, or upon his own spiritual properties, must arrive by some means at the knowledge of what he is. This is that firm practical ground upon which Socrates placed philosophy, abundantly justifying the opinion of mankind that he had given it a honest, less airy character than belonged to it heretofore; this is that deep invisible ground upon which he placed philosophy, abundantly justifying the indignation of those wits who complained that he forced men to more painful exercises of thought, and involved them in profounder mysteries than all his predecessors. A few words respecting the schools which owed their origin to the disciples of Socrates will illustrate these remarks; will show how great a revolution he had accomplished; will explain how far it is possible to separate the practical from the mysterious in philosophy, and will enable us to establish the assertion that Plato was guilty of no fraud, but evinced his singular honesty, his insight into principles, his skill in the choice of means, and his admirable modesty, by making Socrates the expounder of truths which, in their fulness at least, he himself had been the first to unfold.

Socratic
schools.

The Cyre-
naic school.
Aristippus,
Theodorus,
Hegesias,
Anniceris.

The immediate outgrowths of the Socratic philosophy and discipline were three schools, ordinarily distinguished as the *Cyrenaic*, *Cynic*, and *Megaric*. These may be said to be the parents of the most conspicuous theories with which later Greece was occupied. The Cyrenaic doctrine, having mingled with a tributary stream flowing from the physics of Democritus, terminated in Epicurism. The Cynic combined with the Megarian to constitute Stoicism. The Megarian moreover contributed one element to the important speculations which had their home at a much later period at Alexandria. It is interesting, therefore, to trace the leading thoughts of each, and to show how they originated with Socrates.

Aristippus of Cyrene seems to have been a man of a singularly easy, happy temperament. Never having been troubled with any internal conflicts, and having probably a healthy frame and a good digestion, he found little in the world to annoy him. Pleasures excited him not, pains passed lightly over him. Few men, one would have thought, would have had less sympathy with Socrates, who was a hard fighter all his life long with himself and with the world. Nevertheless this earnest thinker had charms even for Aristippus. Socrates said that we are not to yield to circumstances, but are the masters of them; and the light spirit which no circumstance affected or oppressed found an interpretation for the maxim in his own experience. The perturbations and restlessness of the thoughtless, unrecollected man were frequent topics for the pity and warnings of Socrates; could there be a more natural inference than that freedom from annoyance, a dismissal of all careful and turbulent anxieties, is the great end of philosophy? In addition to these, the well-known common-places of his master's discourse, Aristippus could no doubt quote

authentic fragments of his conversations, in which he had seemed to assume pleasure as the end of life, and to adjust his other maxims to this conclusion. He could tell, we may be sure, of cases in which Socrates, addressing himself to his own lazy, voluptuous habits of mind, and reprehending them, had yet seemed to make it his object to prove, not that they were leading to a wrong end, but that they were ill-chosen means for accomplishing that end. Aristippus, therefore, easily persuaded himself that he had a good title to call himself a Socratic, nay, that he was the best and most complete interpreter of the Socratic views, when he announced the great discovery, that pleasure and pain are the ultimate principles of human life; that the pursuit of the one and the avoidance of the other is and must be the business of every man. Whatever honour belongs to the first formal promulgator of a doctrine which has occupied so prominent a place in the philosophy of all ages as this, must in all justice be given to Aristippus. That in which he is distinguished from later and less practical reasoners of the same class is in the distinct and honest assertion, that the momentary, concrete gratification, and not the complex notion of happiness, is and must be the object of men's desires and labours. It was easy for Aristippus to adjust some other portions of the Socratic creed to this doctrine. If the choice of what is agreeable, and the rejection of what is disagreeable, be the great virtue of the human soul, how conveniently might the language of Socrates respecting the connection of virtue with reason and knowledge be pressed into the service of the new sect. Of course it is the intellectual faculty which prefers and discards, and why should not these acts of judgment be the same with those acts of reason, that perception of what is and what is not, to which the master had so constantly referred? And as for the apparent self-restraint and bodily privations of Socrates, these were in no real contradiction to the Cyrenaic theory, which admits, of course, all varieties of taste, and may well permit one man to seek mental pleasure at the expense of corporeal, another corporeal by the loss of mental. This school underwent several changes. In the hands of Theodorus pleasure and pain ceased to be real outward objects, and self-seeking and self-glorification became the defined, acknowledged ends of the wise man. In Hegesias the hope of attaining pleasure is exchanged for a mere invention of contrivances to avoid pain. Anniceris seems to have taken off the rough edges of the doctrine, and to have prepared the way for its merging in the more general notions about happiness which were matured by Epicurus.

The Cynic school—as it presents itself in the persons of Antisthenes, its founder, and Diogenes, its only very notorious disciple—is the formal opposite of the Cyrenaic. Yet they added one to the numerous illustrations of the old maxim, which Mr. Coleridge has observed to be of all maxims the most pregnant for the philosopher and the philosophical historian, “Extremes meet.” Both in fact started from the same Socratic maxim; both may probably have alleged the same discourses in vindication of their system. The wise man should not submit to circumstances, but rule them, said Aristippus; his whole business is to arrange his circumstances that they may produce the maximum of pleasure, and the minimum of pain. A man is to be superior to his circumstances, said Antisthenes, and therefore he is by all means to overcome his sensibility

to pleasure or pain, and endeavour to live solely within himself, cultivating that nobler part of him which is not affected by outward impulses and impressions. If the first could allege passages from the discourses of Socrates in support of his theory, the latter could more confidently appeal to the whole course of his life, to his habitual endeavours after a victory over mere sensations. The Cynics were in fact more disciplinarians than doctrinists. They had a hard dogmatism of their own, but they were much more ambitious to show their own indifference to passing accidents, than to discover principles and reasons for such an indifference. Of the two professors of the school Antisthenes seems to have been the honester, Diogenes the more original. The first was hard and narrow, but apparently sincere; the second was an ostentatious coxcomb, from whose proud and insolent spirit were emitted now and then sparks of what might have been genius, if it had been accompanied with simplicity of character and a true purpose.

The Megarian school.
Euclides,
Eubulides,
Diodorus,
Stilpo.

Euclides of Megara was unquestionably a more sagacious and subtle man than any of those we have named. He was attracted to Socrates by no hope, either of obtaining a theory respecting life, or of discovering a scheme of self-culture, but by his unrivalled skill in disputation. Had Euclides lived thirty years earlier, he would have been an Eleatic or else a Sophist. But in nothing is the effect of the Socratic teaching, and the change it had wrought upon the minds of his countrymen, more remarkable than in the moral tone which it imparted to the thoughts of those who would otherwise have been metaphysicians merely. To argue was the taste and the vocation of the Megarian school, but their arguments were all irresistibly drawn to the question, "What is the good?" In pursuing this inquiry, they were naturally led to those pregnant positions of Socrates respecting evil, as a departure from, and rebellion against what *is*, which constituted, as we have seen, the ultimate, and, in one way, the most characteristic part of his philosophy. This principle, in fact, disjoined from all the living processes by which Socrates had arrived at it, and by which he sought to make other men conscious of it, and exhibited in naked opposition to all other ideas of virtue or goodness, constituted the Megarian doctrine. All their labours were employed in disproving the obvious and apparently irresistible opinion, that those things whereof the senses give us information, are the most real and certain. We have heard how Zeno defended the doctrine of his friend and master Parmenides by showing the utter instability of all sensible presumptions and conclusions. The Megarian school adopted the same method. The difference lay in the characters of the respective periods; the purpose of Zeno was to support the metaphysical idea of oneness,—of the Megarian, to support the moral idea of absolute, unchangeable Being.

The history of this school is melancholy and instructive. Euclides, though the bias of his mind was to disputation, felt the grandeur of the moral truth which he had learned from Socrates. In Eubulides positive faith was superseded by delight in his own subtlety, and in the confutation of antagonist arguments. The mere forms of the understanding, apart from all vital principles or results, seem to have been the objects of admiration and reverence to Diodorus Cronos. Lastly, Stilpo seems to have lost the characteristic idea of the Megarian school altogether, while he carried its charac-

teristic infirmity to its greatest height. Not to establish the existence of objective truth, but to show how an intellect may be formed which shall be most impassive to influences from without, and least disturbed by affections from within, was his problem. One of his pupils was Zeno of Cittium, the author of Stoicism.

Moral and
Metaphy-
sical Phi-
losophy.

Plato.

Plato conversed with both Aristippus and Antisthenes. With Euclides he enjoyed a closer intimacy than with either of them; for to Megara he and other disciples fled after the death of Socrates, when it seemed less safe to dwell in Athens. It would be rash to say that the direction of his own thoughts was determined by his observation of these three men, for it is a notion apparently well supported by internal evidence that his *Phædrus* and his *Laches* were written in the lifetime of his master. Yet it seems impossible to doubt that he had very early noticed the tendency in his different fellow-disciples to adopt certain sentences which fell from their teacher's lips, and from these to form systems and schools, and that he had considered very deeply whether there were no course by which he might escape from the like temptation. If Socrates had compounded his creed out of the different systems then prevalent in Greece, it could surprise no one that the elements thus artificially put together should reassert their independence, and in some new shape, perhaps, be claimed as the property of the minds to which they were severally most adapted. But every thing that he had seen of his master made this supposition impossible. The very secret of the power which Socrates exercised over men of tempers and intellects so dissimilar arose from his having been emphatically original. Whether he had studied the doctrines of other schools or no, it is evident that every thought which he uttered came fresh and living from himself, or, rather, was the united fruit of his own reflections and of those of the persons with whom he conversed. It was evident that he had been able to minister to other minds, because he knew so well what was passing in his own, and had sought out every principle as the solution of an actual difficulty. But it is fair to suppose that every philosopher is in some sort an inquirer into the working of his own mind, nay that his philosophy, so far as it is sincere, is an exhibition of his own mind. How then was Socrates, who was so remarkably *himself*, preserved from that narrowness and exclusiveness, into which Aristippus and Antisthenes, both sincere men in their way, had obviously fallen? Plato could only answer the question by supposing that it was the healthy habit of always connecting his own thoughts with outward circumstances, and with the puzzles of the age in which he was living, which prevented the Socratic doctrines in their owner's hands from ever stagnating into a mere theory. The obvious resource for making his philosophy complete and general, and suited to all times, was to strip it of those accidental features which had adapted it so happily to a particular crisis. Plato was convinced, by reflection and experience, that precisely the opposite course was the safe one. The poetry of Homer could be read and enjoyed in the age of Pericles, not because it stood aloof from all temporary and local accidents, but because it was enveloped in them. It was exactly when men were presented to them as they were in an entirely different state of manners, that they were able to realize

sical Phi-
losophy.

them as their brethren and their countrymen. Reasons will no doubt occur in multitudes to the reader, why the analogy of poetry is inapplicable to philosophy; it is sufficient for our purpose that they did not weigh with Plato. No one knew so well as he—no one felt so strongly—the essential difference between poetry and philosophy; he even was betrayed into exaggerations in his attempt practically to assert it. But he was convinced that it did not consist in this, that the poet obtains immortality for thoughts which he utters by adapting himself to the feelings and the temper of the age in which he lives, and the philosopher by divesting himself of them all. He thought he could see that the abandonment of all living and practical sympathies, the attempt to divorce himself from human interests, gives to the philosopher that narrow and bounded character, from which he hopes by these means to deliver himself. If, then, Grecian wisdom was not to retrograde from the point to which Socrates had brought it, or if it was ever to become useful in other countries and periods, Plato concluded that it must not resolve itself into speculations or declamations about this or that scheme of life, this or that principle of action or pursuit, but must be content to exhibit itself in the conversations of actual living men, not of some imaginary day, but of that day, talking about the actual matters of which they did talk when they met in the streets or at their feasts; not taking the least pains to forget the men among whom they were living, or the transactions that were occupying them, or to adopt any more universal mode of thought and speech than that which was common among them.

Why he
selected the
Dialogue.

The DIALOGUE of Plato is not then, as some have represented it, an artistical invention, in which the philosopher sacrificed his severe judgment to his imagination, or to a desire of reputation for dramatic skill with his contemporaries, or with posterity, or to the ambition of presenting his truths in an agreeable form. It is most evident that he regarded it as a necessary mean for the elucidation of the truths with which he believed himself to be possessed; and that he is not at all more anxious to impress any one principle upon his readers than this, that in the Dialogue, rightly used, we have the right induction to all principles. It is strange, indeed, that Plato should be accused of sacrificing the interest of his disciples to a selfish desire of fame, by that method which he has adopted specifically for the purpose of leading them onwards step by step in self-inquiry; or that he should be supposed to have used this as a means of conciliating their favour, when, in fact, it has caused more conscious vexation and irritation to every superficial student of subsequent days, as it did to every superficial talker of that day, than any which his genius could have devised. A mere artist endeavours to carry us at once into noble contemplations, which make us conscious of our own greatness and dignity. It is Plato's continual desire that we should feel our own way into these contemplations, that we should understand that if we would really have them become parts of ourselves, we must ascend into them through very rugged and thorny paths, that we should be aware how many frivolous difficulties we shall be suggesting to ourselves and must clear away if we would really see any thing as it is. His Dialogues are literally an *education*, explaining to us how we are to deal with our own minds, how far we are to humour them, how we are to resist them, how they are to enter-

tain the glimpses of light which sometimes fall upon them, how they are to make their way through the complications and darkness in which they so often feel themselves lost. Nowhere but in the sacred oracles do we find an author so cognizant of our own perplexities, so little anxious to hide them from us; nay, so anxious to awaken us to the consciousness of them, in order that we may be delivered from them. Herein lies the art of Plato. Most consummate art it is we admit; superior in the depth of insight which must have led to it, and in the influence which it exerts to that which is displayed in almost any human composition. Still it is not art, in the sense commonly given to that word; it has no independent purpose of pleasing. It does not work underground, leaving the ordinary man to feel its effects simply, and the thoughtful man to judge of its character by its effects. On the contrary, it most anxiously draws your attention to its own methods and contrivances: that you should enter into them and understand all the springs and valves that are at work, is as much the writer's ambition, as that you should accept any one of the final results. Indeed, he does not acknowledge the results as yours, till in the region of your own inner being you have gone through the processes which lead to it.

This is so primary and characteristic a principle with Plato, that we must be permitted to fix our readers' attention upon it, as that through the understanding of which they must attain to all his other principles. Plato above all men must be studied in Plato. A hearty and sympathizing acquaintance with one Dialogue will do more to initiate a student into what is blunderingly called his system, than the reports of all philosophical critics and historians. There you find no digests of doctrine, no collections of ready manufactured notions, to be adopted and carried away. Every one is alive and at work. The actors too are not, as in our best Dialogues, in those of Berkeley for instance, personages with significant names; they are real Phædruses, Gorgias, and Protagoras, discoursing in a place which is actually ascertained to us by an accurate and vivid description, about some passing question in the folds of which are found to be contained all the deepest and highest principles of our being. These are drawn forth not violently by any predetermination that such and such facts shall give forth such and such a moral, but by the ordinary accidents of conversation, amidst explanations and contradictions, the confusion of disciples, the anger of doctors, clumsy attempts at reconciliation by good-natured by-standers. The dialogue is often a *Siris*. Like Berkeley's admirable treatise, it may be bound here on earth to no worthier a stake than the properties and virtues of tar-water. Oftentimes the starting point may be one far less worthy than this, the lying speech of some sophist in support of some mischievous and vulgar paradox. Yet the chain is unwound with a skill of which our modest countryman would have cheerfully confessed that his was but a feeble copy, till its highest link is felt to be about the throne of Him whose name it was the privilege of Berkeley to utter, the honesty of Plato to declare unutterable.

Thus far we have described Plato as reasserting the entire principle of Socrates against those who had dis- membered it. But a notion has gone forth, and has received support from a highly able and eloquent French commentator of our day, that Plato was an Eclectic; in

other words, that his object on every occasion was to set in opposition two imperfect principles, and, either by merely showing their inadequacy, to suggest the hint, or, by clear exposition, to develop the form of a third idea which should include them both. This is the most plausible shape which the theory has taken. Another and common way in which it is stated is, that Plato framed to himself the notion of a philosophy which, taking its start from the doctrine of Socrates, should adopt into itself all the other Greek philosophies, whether metaphysical or moral, and that accordingly we do find in him not only an attempt to harmonize the doctrines of the schools, which took their name from Socrates, but also of those which preceded him. In both these statements there is, as it seems to us, much truth: yet truth put into a form which is exceedingly likely to mislead a reader, utterly to pervert his notions respecting the real object of Plato, and to deprive him of the benefit which a meditation on these remarkable works might procure him. We suspect that, in considering these theories, we may both arrive at a clearer apprehension of Plato's meaning, and gain some light which will profit us in all our future inquiries.

Moral dis-
tinction the
primary
purpose of
Plato.

One main object of Plato in using the dialogue as his mode of communicating truth, was, that he might discover the meaning that was latent in words which had been disguised by conventional usage, and might lead the inquirer to recognise this meaning as that which had been implied in them from their very origin, and had been really floating about in the minds of those who had given them quite a different signification. Hereby he was carrying out the method which Socrates, as we have seen, had been throughout his life maturing, and to which we have traced the success of all his experiments in moral science. For this practice was grounded upon a faith which it ripened day by day into certainty, that there is in every man that which apprehends and recognises truth; that the truth is continually near him; and again, that his view of it is continually interrupted and distorted by the phantoms which are presented to his senses. In drawing forth this truth out of the mind of the student and teaching him to realize it as his own, consisted, as Plato believed, the great duty of the Socratic teacher; to this all his labours were to be bent; so far as he did this work faithfully, he might hope to be rewarded with greater illumination. Never, however, was it to be forgotten that the discipline was a moral as well as an intellectual one, nay, that it was primarily and essentially moral; that he must resist the attractions and bribery of sense in order to escape her impositions. Now the process we have described leads to a result which often looks very like the result of *Eclecticism*. An opinion seems to be rejected as false, an opinion that is set in opposition to it is shown also to be unsatisfactory, and then at last a truth is seen, or suspected to be hidden somewhere, which both alike had been aiming ineffectually to reach. The reader of Plato's Dialogues will be encountered again and again with instances of this sort. But let him beware of hurrying to the conclusion, that the reconciliation of these opinions, or the construction of another opinion which shall be more comprehensive than both, was the aim of the teacher. If he will quietly accompany him along the road, he will find that in such conversations as these, *distinction* is much more his object than accommodation. To distinguish between those images which the mind shapes for itself out of

the objects of sense when it is sense-ridden and sense-possessed, and that sound meaning and reality which it is capable of perceiving when it has sought to purge itself of its natural and habitual delusions, to teach it the art of rejecting as well as choosing, and to put it in the posture for either one act or the other; this is the intention of Plato. It may be that he has done more to introduce harmony and unity into moral speculations than any philosopher who has ever lived; we fully believe that he has. But he begins with cultivating in us the habit of moral distinction. He begins with leading us to feel that truth and falsehood are radical ultimate contradictions which cannot be accounted for or resolved into any others. To see that which is, as it verily is, this is the highest privilege of the best and wisest men; to see things as they are not, confused, sensualized, corrupted, this is the misery and curse of the thoughtless, slavish victim of inclination. To open that inward eye by which the reality of things is discerned in other men, is the vocation and privilege of him who has himself served an apprenticeship to truth, and feels that he is her servant. Such, we conceive, is the object of one large class of the Platonic Dialogues, which are the induction or vestibule to the rest. In these Plato is distinctly and emphatically Socratic. They must, indeed, differ in a most important respect from the actual conversations of Socrates, in that the end must always have been much more present to the mind of the writer, than it could have been to that of the speaker. Socrates argued with a sophist, and in the course of his argument traced out a line of thought which led his hearers to that ground of reality which his opponent was keeping out of sight, and presuming not to exist. Plato makes the refutation of sophists, and every turn and winding of the discourse, a mean of arriving at the principle which is always before him as the object of human inquiries. In Socrates the strongest feeling seems to have been, "I am certain there is something which is not appearance or phantasy, which man did not shape out for himself, but which will remain when all phantasies have disappeared, which is, and which I must recognise if I would be any thing but a phantom or shadow myself." This was the conclusion of a practical working mind. By earnest meditation upon this conclusion, Plato comes to feel that if there be an unseen reality in all things, a truth, a substance in things, of which the eye sees only the shape and the colour, there must be a truth and substance which has none of those sensible adjuncts, which is in itself, and the beholding of which is the function and highest attainment of the purified spirit. Now the outward shell of this opinion so closely resembles the doctrine of Euclides that we cannot wonder that some critics, in their desire to reduce the philosophy of Plato into fragments, should have pronounced several of the earlier Dialogues to be not in fact his, but the production of the Megarian school. All in which they found this substance, this *το ον*, put forward as the end of human investigations, they naturally connected with a system which had the assertion that good and being are identical for its prominent characteristic. Those who agree with us in the view we have taken will at once see the plausibility of the critic's notion, and its utter untenableness. In no part of Plato's works is the distinction between him and the Megarians so conspicuous as in this where he is asserting their own principle. For by adhering closely to the method of Socrates, by making

his Dialogues not the declaration of a truth, but a mental exercise to arrive at it, he has not only divested the doctrine of all its dryness and prickliness, but he has shown how it is connected with those other more obvious notions to which the Megarian set it in rude opposition. Pleasure is not the good, they said; self-denial is not the good; being is the good. Yes, said Plato, but there is a being in pleasure, there is a reality in it as well as a falsehood in it. Whatever man has found an expression for in language, whatever man has pursued as an object in life, there is in that a truth, a substance, which may be distinguished from the lying phantom which surrounds and counterfeits it. And so far as a man does this, so far does he put himself into the right condition of mind for arriving ultimately at the perception of that truth, that being which is encompassed with no accidents, but which actually is. But then, in order to attain or to cultivate this state of mind, there must be a discipline, a curbing, and contradiction of the lower nature, and therefore this too is a good.

Opinions
reconciled.

Without, then, any purpose of combining opinions, nay, while resolutely maintaining boundaries, and using a most subtle test for the discrimination of the true from the apparent, Plato had actually reduced the three doctrines which assumed the name of Socratic into a certain relation and harmony. It now became him to consider how far this same doctrine and method might be applied to the earlier philosophers of Greece; how far his master had been anticipated by Xenophanes, Heraclitus, Parmenides, or Pythagoras; how far he had thrown back a light upon them which might make their speculations more intelligible and consistent with each other. Here commences, in our judgment, the second class of the Platonic Dialogues, that in which the link between Moral and Metaphysical Philosophy, between the doctrine of being which Socrates had asserted, and the question respecting unity, which had been the great occupation of the Greek mind, is illustrated and developed.

Second
class of
Dialogues.

Our readers will not have forgotten that the leader of the Eleatic school, Xenophanes, was in one respect distinguished from his successors. His language at first sight seems remarkably to accord with that of Socrates. That which he supposed to be the true object of man's contemplation was God, or "The Being." Yet, while doing justice to the course of thought by which he arrived at this conclusion, we were obliged to admit that he was essentially a destructive thinker; that he reduced his Being to a mere negation of human qualities and attributes; and that Parmenides found a much happier expression for the results of his inquiries when he said that they simply led to the affirmation of oneness. How then did the doctrine of Socrates differ from that of Xenophanes? It was separated from it by a whole heaven. The Being of Xenophanes was altogether exclusive, the Being of Socrates was altogether inclusive. If the language of men contained such words as "just," "merciful," "good," if it attributed these names to certain acts, then, whether these words or no had been understood, whether they had been rightly applied or no, there was a reality corresponding to them, there was a "justice," a "mercy," a "goodness," and all these centred and united themselves in The Being. No sophist could embarrass him with the question, "Seeing man also uses the words unjust, unmerciful, bad, why should not these also have

their appropriate archetypes? and why may not these, as much as the others, dwell in that permanent and all containing substance?" For it was assumed in the very hypothesis that all these are departures from that which is, that they are intrinsically falsehoods. Now it was by reflection upon this difference, so delicate yet so vital, so strikingly marking the man who was fighting against all popular opinions and faith from the man who was finding out substance and life in all, that Plato seems to have gained his first insight into that doctrine of Ideas which constitutes the most native and peculiar portion of his philosophy, that which may not wrongly be called its purely Platonic portion. We are perfectly willing to admit the assertion which the other disciples of Socrates seem to have made with no little vehemence, and which Aristotle has adopted from them, that no such principle as this was enunciated by Socrates in any of his discourses. Yet we believe as undoubtedly, that by his steady adoption of the Socratic method Plato arrived at this principle, and that they failed in apprehending it only because they neglected that method. In endeavouring to make this remark clear, we shall also perhaps be able to give our readers such insight as a treatise like this may hope to give into the subject itself.

The Greek word for *appearance* and for *opinion* is the same. An opinion is that which *seems* to each man. Now the whole of the education and discipline of Socrates had been to lead his disciples away from appearances to realities. And just so far as he did this he felt that he was leading them from opinions to knowledge. His experiments upon others convinced him, his own heart told him, that there is in us a thirst after knowledge, that with less than knowledge we cannot be satisfied. These at least are Socratic assertions; no one pretends that these were palmed upon him by Plato. But how could this be? The essence, the being of a thing, or of a person, seems shut up in that thing or person. I may acknowledge that it is there, but how can it ever come within the region of my perceptions? Must it not be after all some shape or image or phantom of this thing which I take account of, and not the very thing itself? Supposing this were admitted, the Socratic philosophy falls to the ground. And what falls with it? Not a scheme or a system, but the faith that truth is any how cognizable by man, the faith that he is not the necessary dupe of shadows and impostures; the fact that he is a moral being. It was not a doubtful question whether these results would follow from such a determination as this; they had followed; the practice and education of Socrates had been nothing less or more than a deliverance from them. The sophists had turned the world into a shadow world, in which they could safely practise their juggleries. It was that great assertion that something is, and that what is only may be known, which had discomfited them, and made a mock of their subtleties. Yet unless this great practical puzzle could in some manner be resolved, the conclusions of Socrates, however ascertained to be sound by the reason and moral feeling of every one who fairly worked them out, would be liable to continual assaults on the side of the understanding. On this point, too, Plato was not left to his own conjectures. The sophists had stolen their armour from the real, the honest philosophers of Greece. They had not dared to grapple with this difficulty, and the proofs which they had left of its existence in their speculations

had been eagerly laid hold of by those who knew so well how to suck the poison out of every flower.

We have intimated that a faithful and affectionate study of the strange, earnest thoughts which occupied Heraclitus might be profitable to any man. But his sayings concerning the endless vicissitude of things, and the falsehood of all human conjectures, made far more impression upon the Greek mind than his deeper thoughts respecting the universal light in man, and the power he possesses of conversing with that which is universal. These latter sentiments had only connected themselves with the vague pantheistic notions which were now gaining ascendancy, (notions probably very far indeed from the mind of Heraclitus himself, who thought it the ultimate wisdom to know the name of Jupiter;) the former, in the hands of Protagoras, had become a system which excluded all feeling of constancy and permanence or order. One man has one notion of the things which he beholds or meditates upon; one man another. Any one of these notions may be as right as another, and that we cannot have more than such notions, that we cannot arrive any more nearly to the truth of things, is a proposition not so much to be proved as to be taken for granted. Meantime the Eleatic "fixedness," which was the formal opposite of the Heraclitean "flux," served the purpose of the deceiver equally well. To be able to deny the fact of plurality, and so embarrass the minds of men respecting the objects of their worship, was just as convenient a line of policy as to upset their faith in their own convictions. Such observations might have led another man to despair of all inquiry; they only gave Plato a stronger moral interest in prosecuting those upon which he had entered.

Notions
and ideas.

All the notions, you say, which the mind forms respecting that which the bodily eye sees, or that which its own inward eye sees, are confused, fluctuating, contradictory. My notion of the flower is not the very flower; my notion of what is just is not the very just. Most true, Heraclitus; most true, Protagoras. But these notions are indexes, guiding-posts to that which is not false, or confused, or contradictory. This notion of the flower and of justice proves that there is a very flower—a very justice. Again, the mind is capable of beholding the Being, the One. But of this Being, of this One, all the notions, imaginations, premonitions of the sensual understanding offer most miserable and counterfeit resemblances. True, Xenophanes and Parmenides; yet there is that in this Being, this One, which does and must answer to these notions that which they are trying, however vainly, however awkwardly, to express. If, then, we connect the results of these inquiries, which start from such opposite points, what follows? There are forms permanent and unchangeable in which that which is manifests itself as it is; in which we behold it as it is. Are these forms, then, in the beholder, or in that which he beholds? We answer; the region of pure being, that in which the inner mind dwells, may be (one might expect that it would be) under some corresponding law to that of sensible phenomena. At all events there could be no *a priori* presumption against the doctrine that as a sound cannot, by the very nature of language and of things, be referred only to that whence it proceeds, but likewise involves the supposition of an ear which receives it, so there may be such a presentation of that which actually is, of the substance or essence of each thing, as can neither be understood merely in

reference to that thing, nor merely in reference to that whereunto it is made, but must by its nature be spoken of as appertaining at one and the same moment to both. But then this presentation cannot by its very nature be fluctuating or variable, it must be permanent and substantial, or it cannot make known that which is permanent and substantial; it must be the very opposite to that which is its parallel in the world of sense. Are we to say of such ideas or forms that they are eternal as well as substantial? To answer "yes" would perhaps startle no one, if these ideas or forms had merely reference to justice, goodness, or even beauty. But when we speak of the actual flower and tree that we behold as having a primary form or idea, is there not something dangerous in a doctrine which would represent such forms as eternal? The reply is, that this statement would do but very partial justice to Plato. For if in the minutest thing he believes that there is a reality, and therefore in some sense an archetypal form or idea, yet he believes also, just as firmly, that every idea has its ground and termination in one higher than itself, and that there is a supreme idea, the foundation and consummation of all these, even the idea of the absolute and perfect Being, in whose mind they all dwelt, and in whose eternity alone they can be thought or dreamed of to be eternal. This remark may also relieve the doctrine of another objection. These ideas, being by their very nature substantial, must be substantially in him who perceives them. It is only seeking to remove the difficulty a step further from us, and falling into a contradiction and absurdity in the attempt, to suppose that there are indeed forms or ideas of things, but that we have only notions or conceptions of these ideas. The idea itself must be considered as with us and in us; the notion which we form about that whereof it is the idea, when we begin to use our senses, to compare and to reflect, must not be identified with the idea, but is a witness and proof of its presence, and that we are feeling after it; to realize or to possess the idea is to have the science or the knowledge of the thing. But then this assertion, that these ideas are substantially with us, must be taken in connection with what has been said before, and it will be seen at once that, instead of affirming the ground and root of our knowledge to be in ourselves, this is the very falsehood which Plato was seeking to overturn. These ideas are the witnesses in our inmost being that there is something beyond us and above us; to enter into the idea of any thing is to abdicate our own pretensions to be authors or creators, to become mere acknowledgers of that which is. And to enter into that deepest and ultimate idea, which is the ground of our being, must be in the deepest sense an abdication of our own notions and imaginations, an act of submission to, and reception of, the Truth.

Here, then, we find Plato most consistently carrying out the principle which it had been the vocation of his master from first to last to assert. Here we see how perfectly harmonious the Socratic doctrine, that knowledge is the end of life, is with that humility and confession of ignorance which are at the root of all the Socratic discipline and culture. Here we see the harmony between knowledge and being; how necessarily a certain state of character and affections is presupposed in every act of knowledge. Here, lastly, we see how truly Plato did reconcile those two forms of philosophy, one of which had dealt with the objects of our knowledge, one with our acts of perception—how truly he did

discover a truth, one side of which each had dimly perceived, yet how little this was the result of any project for harmonizing opposite theories,—how much rather it was the effect of resolutely pursuing a principle which supersedes theories altogether, and so far as it is faithfully acted upon, delivers us from our bondage to them. Not to frame a comprehensive system which shall include nature and society, man and God, as its different elements, or in its different compartments, and which therefore necessarily leads the system-builder to consider himself above them all, but to demonstrate the utter impossibility of such a system, to cut up the notion and dream of it by the roots, this is the work and the glory of Plato. He who is attempting the construction of such a Babel must understand not merely that he will not find the model of it in Plato, but that before he advances one step he must undo every thing that Plato has done, must disprove all his conclusions, and prove the falsehood of the process by which he has arrived at them. Those commentators who can find in Plato nothing but the most exquisite ridicule of all the system-makers in his own and in past days have, it is true, understood him imperfectly. That ridicule would not be so delightful and satisfying as it is, so thoroughly genial and consolatory to every earnest student, if he did not feel that it was the handmaid of the most severe demonstration, that it was only another aspect of the most generous and noble sympathy with every thing that is honest and humble, and practical and true. The kind and experienced teacher smiles at our useless waste of time in attempting to build, but it is that he may urge us to the more profitable occupation of seeking after the foundation of that which is built. The one is the employment of those who desire to be gods, the second of those who believe that the highest blessing of which man is capable is to know God.

His sup-
posed clas-
sification.

But if it be true that Plato is almost free from that propensity for theories which has beset most philosophers, nay, that his principle, consistently followed out, is positively incompatible with them, how is it that he is so commonly supposed to have mapped out the domain of human knowledge into the three provinces of Dialectics, Ethics, and Physics? In considering this question we shall perhaps discover the purpose of a third class of his Dialogues, and be able, moreover, to contemplate his so called Eclecticism under yet another aspect.

His dialectics and
ethics inseparable.

The critics who have discovered this classification in Plato evidently cannot mean that there is one portion of the Dialogues which does, and one portion which does not treat of dialectics. They must be aware that every dialogue exhibits the dialectic method of Plato, that every one is making with more or less success some new trial or application of it. Neither, we think, can they pretend, without doing violence to the purpose and language of their author, that these dialectical dialogues are not also ethical. Not only is a moral purpose conspicuous throughout them, but, as we have said before, the development of the method by which the truth is perceived and ascertained is inseparably interwoven with a moral culture. The disengagement of the mind from sensible impressions and sensible fascinations is the joint effect of restraint upon inclination and of the art by which the apparent is distinguished from the real. Without the feeling of this connection and intertwining of the ethical with the intellectual discipline, the most beautiful Dialogues are unintelligible; nay, the desire to separate that which Plato has believed inseparable, is

perhaps the main cause of the narrow and partial views which have prevailed as to the object and construction of his works. Look, for instance, at the *Phædrus*. Lysias had proposed a certain thesis respecting Love, and had defended it with abundance of ingenuity in studiously balanced sentences, the aptest clothing for a sophistical purpose and a sophistical method. Socrates shows, first, how easy it is to meet his arguments with a counter series as ingenious and as artificially expressed. Then he discovers the radical defect of both sets of arguments, that they were dealing with a word, the meaning of which had not been ascertained. In the attempt to discover what this word signifies, to separate the true from the apparent meanings of it, he unveils the whole principles of his dialectics. But there is combined with this exposition the most distinct declaration and warning, (assuming a form which, however unfit for us, was most appropriate to the evil condition of Greek society, and proves the purity of the writer, who, in the midst of such a society, could maintain so elevated a standard,) that only by restraining the grosser appetites can we be in a state for apprehending the true nature of Love. In the conclusion of the Dialogue, the two principles are harmonized in a splendid mythus, wherein the disciple is taught that only he who governs himself, who has his lower nature in subjection, can be fit for the highest exercise of his faculties, for the contemplation of that which verily and indeed is. We cannot reduce this Dialogue under any of the partial names and descriptions that have been given of it. We cannot consider it a mere attack upon the rhetoricians, or a mere development of the Socratic method for testing the meaning of words. Neither does it seem to us a treatise on pure love, or on the idea of beauty. All these subjects may be hinted at, and even most valuably illustrated. But the reader of the *Phædrus* must be contented to feel how they sustain each other, and to let them form themselves into a whole in his mind, without being eager to give the absolute supremacy to any one of them. He will then find, we believe, that this Dialogue is one of the most conspicuous, we might say the type dialogue, of that class which teaches us how to make substance or being the end of our inquiries and meditations; but he certainly will not be able to discover whether it is more ethical or dialectical. The *Gorgias* is another almost equally striking instance of the same kind. Formal critics have determined that this too shall be merely an attack upon rhetoric, or else that it shall have the merely moral object of explaining the nature and purpose of punishment. It must strike a person, who only hears of this discussion, that a work which could suggest such opposite interpretations must be most incoherent and rhapsodical. The more he reads it the more he will be struck with the sequency of its thoughts, with the natural and easy manner in which one grows out of another. And he will find, we believe, upon reflection, that as the intellectual purpose of the sophist was inseparably combined with the moral, as the pursuit of political power for an end was inseparably united to the cultivation of a treacherous art as the means, so it was impossible to introduce a sounder intellectual discipline among the youth of Athens, without leading them at the same time to perceive that the true purpose of their lives was not the acquisition of dominion or the escape from suffering and punishment, but the attainment, even through suffering, punishment, and disgrace, a deliverance from the moral evil

which obstructed their search after truth, and made power a curse to them. Here, again, he distinguishes the true from the apparent, not by the help of ethics without dialectics, or of dialectics without ethics, but of both conjointly. How the case stands in reference to physics we shall have to explain shortly. But thus much we may affirm now, that whensoever his opponents have engaged in physical speculations, Plato is not unwilling in those Dialogues, which have most distinctly a moral purpose, to cope with them, and that he never in such wise divides these two provinces as to suggest the thought that the principles by which either is governed may not most usefully or injuriously affect the other.

The *Theætetus*.

Of this fact we could easily convince our readers, if we could afford space for an analysis of the *Theætetus*. But we must do no more than commend that exquisite specimen of Platonic wisdom to their careful study, and proceed to show how the notion that Plato established a formal division in the subjects of human thought may have originated, and may be reconciled with our belief in his hatred of theories and consistency of purpose.

Search
after unity.

We have often observed that the founders of the different schools in Greece had been led by the circumstances of their position, or by the peculiar tendencies of their own minds, to choose for themselves a distinct sphere of observation. It was no forethought or wish to be a natural philosopher that drew Thales into his course of speculation. It was merely that the outward facts submitted to his senses were those which struck him as most likely to contain the solution of the problem which he found within. Accordingly, many political and ethical theories may have been mixed by him, as we know they were by Heraclitus, with the physical doctrine from which he started. In like manner Pythagoras was led by a series of scarcely known or acknowledged influences gradually to desert the maxims of his native soil, and to make Society, or the State, the subject of his inquiries. To these we know he added a scheme of nature which he tried to reduce under the same law as the facts which related to the order and government of men. Parmenides and Zeno again entered into their purely metaphysical region, not from any resolution of choosing one province of thought more than another, but merely by reflecting upon the two preceding systems, and finding that they were inadequate. They too sought to make their own system universal, and to make the scheme of the political world and of nature, in some sense dependent on the laws which concern the region of pure mind. Plato then found the fact already established for him, that there actually are these three lines in which the thoughts of men, when they are strongly exercised, naturally run. He had not to create any artificial distinctions; the natural distinctions had been discovered by the experience of his predecessors. What remained for him? To follow them into each of these regions, to inquire how far any of them had discovered the unity of which he was in search, to consider whether what they had looked for in nature, in society, in the mind of man, may not be implied indeed in each of these, yet have its foundations beneath them all. This, we believe, was the final and consummate effort of the Platonic philosophy. As there is a set of Dialogues which seem to us designed merely to unfold the Socratic doctrine of Being, another expressly intended to develop the principle of Ideas, as necessary to the support of the former, and as solving a problem which the Heracleitans and Eleatics

had shown to exist, so we believe there is a third in which Plato reflects upon his master's discoveries and his own, and exhibits them in direct application to the three subjects of nature, of society, and of knowledge. Every one will recognise in the *Timæus* an attempt to discover a unity for the external universe; in the *Republic*, an attempt to discover the meaning of political unity. And, therefore, without contradicting our previous assertion that, in all his Dialogues, Plato is evolving a dialectical method, we may also admit that there are some in which he proposes himself the direct and formal aim of showing how this method is a guide to the true unity in knowledge. Nor must it be forgotten that Plato was enabled by his position as a reviewer of past systems, was obliged by his position as an expounder of Socratics, to reverse the order which we have followed in tracing the rise of these schools historically. He not only might begin with those principles which the Eleatics had expounded, and descend to the natural speculations of the Ionians, but he could not follow any other course if he was to make the Socratic doctrine of Being, and the Socratic method of distinguishing the real from the fantastic, his guiding stars through the whole journey. Here, then, we must begin our notice of his experiments in search of unity. We are eager to introduce our readers to that which we consider the crowning labour of his life, the end at which he was obscurely aiming through the whole of it—his POLITY; but we must first refer to his discussions respecting the conditions and meaning of SCIENCE. A few words will then be sufficient for the less important, though by no means uninteresting, question—how far his views respecting the PHYSICAL WORLD were in conformity or disagreement with his other principles.

There was one great and obvious difference between the position of the Parmenideans and that of the Pythagoreans or Ionians. No one could doubt that they had a real subject for their inquiries, let those inquiries be as idle as they might. But the Eleatic had to produce both the dream and the interpretation; to maintain that there was a region of a pure mind, as well as to show what was transacted there. Plato, therefore, had also two tasks. He had to show that their assumption was sound, before he ventured to inquire how far it was able to carry them. For this purpose he adopted a method which has greatly puzzled many of his readers. In the Dialogue entitled *Parmenides* he introduces Socrates, full of youthful vivacity, broaching the doctrine of ideas in opposition to the antiplurality doctrine of Parmenides and Zeno. The aged philosopher treats his antagonist with most graceful courtesy, allows him to put forth one explanation after another of his scheme, shows him that all are untenable, then encourages him to hope that, after a more severe philosophical training, he will understand himself better, and finally proceeds to establish his own doctrine of the One in a series of annihilating propositions, wherein he shows that it must exist, and that it cannot exist under any conditions or limitations with which the understanding is acquainted. Probably no one but Plato ever ventured upon such an experiment as this—the experiment we mean of showing that his own principle was untenable except so far as it is connected with and grounded upon the principle of another philosopher who did not recognise it. But this Dialogue of the *Parmenides* does not merely serve the purpose of establishing the truth that the mind witnesses of something which is not under sensible

laws, but it also prepares our minds to feel the want which the Eleatic doctrine could not satisfy. A conviction of the purely negative character of the method grows upon us as we read, and while we assent to its conclusions we feel an increasing moral interest in seeking for some higher point of view from which we may contemplate it, and that imperfect substitute which the young Socrates had proposed for it. In the *Sophist* this wish is to a great degree realized. There we have an Eleatic stranger discussing with the young Theætetus the meaning of the word Sophist, and the qualities of the animal which it denoted, how far it belongs to the same genus with the Philosopher, or how they are distinguished. In the course of this dialogue we arrive at the conclusion that the great object of the sophist is to set up a universal science. By universal science he means merely a capacity of talking upon all manner of subjects, of framing a set of images of that which is, and passing these off for substances and realities. But here a difficulty arises: Parmenides, whose opinions the Eleatic stranger might be supposed to favour, has told us that we are not to inquire respecting that which is not; that the conception is in fact an impossible one. How then will our definition of the sophist practically avail us? How shall we be able ever to pursue him on to that ground whereunto we have had the clearest evidence that he has betaken himself? The Eleatic stranger finds himself obliged then, much as he fears the guilt of parricide, to inquire into the soundness of this doctrine of his honoured countryman and teacher. By degrees the fallacy unveils itself. We find that in refusing to recognise the notion of not-being, he was in fact shutting his eyes to something which is. The contradiction may appear startling, but we do not escape it by refusing to look it in the face. We have actually stumbled upon an instance in which that which is adverse to reality must be treated to all intents and purposes as real. And when we look a little further into the use of language, we see more and more the impossibility of giving that definite rigid exclusiveness to the word or notion of being which it must bear in the system of Parmenides. We find that we cannot by any means identify our notion of sameness or of difference with our notion of being. And yet the notion of being enters into both of these; there is a sameness and a difference between things. Whither does all this lead? It leads to the conclusion which, as is so constantly the case in Plato, is carried more directly home to our understanding than it is expressed in words, that Parmenides is after all dwelling in a region of words. For all that he seems to have sounded the very inmost depth of thought, and though he has actually discovered that there are depths which words do not reach, yet he himself is at last only setting up one notion against another notion. It is not Being, but the notion of being which he has been investigating, and which he has necessarily investigated most imperfectly. And now, then, the vision of a new kind of science wholly unlike that of the sophist, yet in one sense as universal as his, wholly different from that exclusive dogmatic notional philosophy of Parmenides, yet like his, having unity for its condition and ultimate ground, opens upon us. This is the science of Dialectics, the science expressly appertaining to the philosopher. It is that which rejects no form of thought or language as unfit for its investigation, but searches out the idea of each, and ascertains what notions and phantasms are inconsistent with it, and attach themselves to

it, and have sought to make themselves part of it. Being it looks upon as the object of its search, but being connected with life, connected with power, not a dry abstract notion, the mere negation of other notions. This must be the science of sciences; not because it reduces all forms of thought to one, or because it includes all existing sciences, but because it discovers in all forms of thought an ultimate ground of unity beneath them all, because it assigns to each science its specific object, and its relation to every other.

Every science is seeking after a foundation. It rests upon the faith that there is a law for the facts which it inquires into; what that law is, is the subject of its inquiry. The science should explain to us how the mind proceeds in the search after these laws through whatever set of facts we may be looking for them. But its own specific object is the deep ground of all laws, the being from whom they derive their life and potency. This dialectics then is the search after premises. Parmenides and Zeno had gone no higher than to the notion of a Logic which, taking the premises of the mind for granted, should affirm what conclusions will legitimately and necessarily flow from it. This was in fact their universal science, as Rhetoric was that of the sophist. The first overthrew all facts, setting up a law in the mind in opposition to them. The second confounded law and fact, using certain laws of the mind to overturn admitted facts, or the contradictions of facts, to disprove the existence of law. The principle of seeking for laws in and through facts is the principle by which Socrates upheld the faith and morality of men against the invasions of Rhetoric, and by which Plato upheld the possibility of discovering science against the invasions of Logic. Here is that inductive science which two thousand years after had to maintain the same battle against the same enemies, when it for the first time clearly and efficiently asserted itself as the only guide to a knowledge of the physical world. The Socratic doctrine of being, makes us feel that it is necessary. The Platonic doctrine of ideas makes us understand that it is possible. The demand in the mind for a unity which shall be not negative, but positive, not the amalgamation of parts, but that which preceded all distinction into parts, and remains unaffected by it; this makes us confident that it is real.

The connection between the Platonic dialectics and the Platonic politics is indicated by several passages in the dialogues, which are intended to unfold the character of each. Thus in the *Sophist* the Eleatic stranger proposes to examine the meaning of three words, *sophist*, *philosopher*, *politician*. The last is reserved for a separate discussion, and actually forms the subject of one dialogue. But it is obvious that Plato intended us to feel how strong was the relation between the three persons denoted by the words, and how impossible it would be to investigate the last without a previous knowledge of the other two. We have had occasion to remark already, that while the sophist sought to make his rhetoric a substitute for all knowledge, his real object was to make it subservient to political ends. The young Athenian, under his teaching, began more and more to feel that the rhetorician and the statesman were convertible terms, that the efficient and practical ruler of men was the efficient master of words. On the other hand, it is obvious that the logic of Parmenides and Zeno must have made politics a mere set of abstract propositions, to which an earnest and enthusiastic man might impart a practical meaning and life, but which would in fact lose

Metaphy-
sical Phi-
losophy.

Moral and
Metaphysical
Philosophy.

all the qualities which had endeared them to him as a logician, in proportion as they received this impregnation. Zeno himself was probably a specimen of this class, but we have no reason to suppose that he left any successors; his disciples must either have devoted themselves merely to inquiries respecting entity and unity, or have become politicians of the rhetorical kind. Now it is obvious that the dialectics of Plato, by their very nature and definition, could not pretend to be themselves politics. They necessarily assumed facts, not indeed as premises to start from, but as the raw materials, in the heart of which premises lay hid. The laws and conditions of society were to be investigated by this dialectic, could not be investigated without it; but they were presumed to exist, and they were perfectly distinct from the faculty and science by which they were discovered. Plato then was in a condition to do justice to Pythagoras as he had done justice to Parmenides. He could believe that there might be much in the discoveries of the one respecting the order of society, as there had been much in the discoveries of the other respecting the conditions and requirements of the pure mind, and he prepared himself to use the philosophy which he had ascertained to be true in one region for an investigation of the observations which had been made and the doctrines which had been broached respecting the other.

But this is not all. The reader of Plato's *Republic* will discover, not, perhaps, without some surprise, that questions respecting the nature and objects of dialectics occupy a considerable place in this political treatise. Hence it has been inferred that the title of the work is altogether misleading; that it is not the purpose of Plato to teach us the conditions and the relations of a state, but merely to raise a platform upon which to carry forward with more interest, and probably with greater success, the philosophical inquiries which he has commenced in his other Dialogues. The *Republic*, according to these commentators, is a kind of laboratory which he has built for the purpose of pursuing his experiments into the nature of the individual man. On many accounts this hypothesis will be likely to find acceptance in this day, even if it had not been supported by talents and erudition of the first order. We are not anxious to refute it, but we are anxious that our readers should study the *Republic* with a free spirit, and that they should not be hindered by a theory from perceiving how it illustrates a subject which has occupied us so much already, and must occupy us at every step of our future progress; we mean the relations between the mind of man and the constitution of society. To Plato we believe was committed the task of expressing the deepest wants and necessities of our being, and of discovering or prophesying the kind of satisfaction that must be provided for them. We make no apology for dwelling so long upon his name in this rapid sketch of moral and metaphysical inquiries, because we are satisfied that if we put our readers in a right course for studying his works and those of Aristotle, and the Jewish Scriptures, they will be able to trace with little assistance from us the progress of these inquiries in modern Europe, whether in the age of the fathers, of the schoolmen, or in the period since the Reformation; whereas the most able and elaborate discourses upon the ethics and metaphysics of later times without this preparation can we think avail them very little. It must, therefore, be a great point with us to ascertain whether Plato is silent upon those wants which belong to our social being and

position; whether he thought them of a purely secondary and accidental character; or whether he found them so imbedded in the constitution of man that he could not investigate the law of each man's internal life without also investigating that by which he is related to his fellows. The supporters of the former opinions (as the readers of Schleiermacher's Introduction to the *Republic* will perceive) have felt that they needed and have not failed to exercise the most admirable ingenuity in working out their conclusion. Those who adopt the latter may content themselves with beseeching attention to the express language of Plato, and with briefly recapitulating the heads of his dialogue.

We find ourselves at the beginning of the *Republic* in a circle of Athenians met to witness a religious ceremony lately introduced from Thrace. The most prominent and interesting person in the group is old Cephalus, a cheerful and benignant octogenarian, with whom Socrates begins a discourse on the comforts of old age, and the advantage or disadvantage of riches. A remark of Cephalus leads to the inquiry, whether the definition of justice given by Simonides, that it consists in speaking the truth, and giving to each man that which is his due, is satisfactory or no? Cephalus being called away to perform a sacrifice, his part in the dialogue devolves upon Polemarchus. But we have not advanced further in the discussion than to a general consent of the parties that the mere external acts indicated in the words of Simonides cannot satisfy the idea of justice; and again, that its obligations cannot be affected by our position to each other as friends or enemies; when the sophist Thrasymachus breaks in with a vehement assertion that the whole notion of justice is a fraud practised by the strong man upon the weaker. The consequence, that the life of an unjust man would be in itself desirable, is one from which he does not shrink, and to the examination of this doctrine the greater part of the first book is devoted.

In the beginning of the second, we find young Glaucon and Adeimantus professing themselves dissatisfied with the manner in which Thrasymachus has defended his cause, and with his haste in abandoning it. They have no sympathy with his views, they are convinced in their feelings that justice is intrinsically good, but the arguments by which it is proved to be so seem to them inconclusive. Is it not true that society has put honour on a certain course of conduct which ministers to its own security and advantage? Has it not succeeded in helping out the weakness of its own sanctions by religious feelings and terrors? Are we not brought into the world under this twofold set of impressions in favour of what is called justice, and against injustice? Can we suppose a man retaining the idea and practice of justice in opposition to laws and his fellow-men, and without the imagination of some divine sanction or patronage? The question Socrates allows to be difficult; perhaps it cannot be at once answered. But might we not arrive at some solution of it if we examined it upon a larger scale? The question presumes an existing state of society; it supposes this notion of justice, be it a fiction or reality, to be necessary to the support of a state. Shall we inquire then how it becomes necessary to a state; what justice in a state is? Then possibly we may know better what justice in an individual is, and whether it can or cannot be maintained under the disadvantages imagined by Glaucon. Now we would remark in passing, that those who consider the political

Moral and
Metaphysical
Philosophy.

Moral and
Metaphy-
sical Phi-
losophy.

part of the *Republic* merely accidental and subordinate, look upon this introduction and upon the manner in which the subject of a state is introduced as the great staff of their theory. They maintain that it is altogether so much easier and more consistent to believe that the subject started in the outset is really the main and central one of the book, and that all subjects which may occur by the way are merely intended for the illustration of it, that no student of Plato who really understands that teacher's method will tolerate any other supposition. We admit at once that this is the object of Plato, that the *Republic* is an inquiry into the nature and meaning of justice; that if this end be lost sight of, it would be quite impossible to understand the connection of its different parts. But then we say that the most natural and obvious construction of Plato's words leads to the belief that the idea of political justice was in his mind inseparable from that of individual justice; that this was precisely the quality which he perceived to be the meeting point between the spheres of ethics and politics, say, rather, which proved that these are two concentric spheres. The clear establishment of this relation is, we conceive, the great purpose of these two first books. They are a lesson to all future reasoners with sophistical men, that they can only maintain the moral ground safely when they are content to follow their opponents on to their own political ground, when, instead of contending that there is an order which the individual is obliged to follow, supposing society to have no existence, they will be at the pains to prove that there are eternal principles involved in the constitution of society itself, to which its individual members will conform themselves, not because they are content to sacrifice their own distinct personality, but because they have no other way of asserting it. Whether the ethical writers, from Hobbes to our own day, would have fared worse or better if they had attended to the admonition of the most experienced and subtle of all the antagonists of sophistry, we may have occasion to inquire hereafter. At all events, those who believe that the main purpose of the Platonic Dialogues is to discover and develop a method of thought, must, we think, be strangely hampered by a theory which compels them to suppose that on this occasion the result arrived at is the only important consideration; and that the processes for attaining it are altogether artificial, and yet withal most clumsy and cumbrous.

But to return; starting with the hope that the proposed scheme for seeking after justice in a state will lead to a solution of our difficulties, Plato proceeds at once to the formation of a society. Now any one who looks in the arrangements which he here sets forth for the outlines of some imaginary perfect commonwealth, will unquestionably be much disappointed. So far from there being any thing mystical or Utopian in his primary conception of the society, every thing is as terrestrial and common-place as the merest materialist could desire. Men meet together and find that each is not sufficient to provide for his own animal wants. Different necessities arise, different capacities discover themselves among the persons associated adapted to these necessities; hence division of labour, distinct occupations and professions. By and by comes the desire for an excess of the good things which earth produces; hence tumults and external wars. Now we feel the necessity for a set of guardians or watch-dogs of the state—what manner of persons must these guardians

be? Clearly they are in danger of becoming wolves instead of watch-dogs. How is this to be prevented? How are we to produce in them those internal qualities which are so obviously necessary for the welfare of the whole community? We say that these arrangements are very unlike what might be expected from the builder of an imaginary commonwealth. No assumption of any advantageous position; no previous theory about the wants and feelings of the persons composing the society; above all no hope, by outward contrivances and dispositions, to avert the occurrence of crime. How can this be accounted for? Does not such apparent carelessness about external contrivances rather favour the notion that the society is only a scaffolding? We answer, if it were so we should be utterly unable to account for the scaffolding not being more elaborately constructed. If Plato had the liberty of forming his own plan and choosing his own materials; if it were a matter of utter indifference to him how far these are consistent with the nature of things provided they did but help him to a discovery which will afterwards be good and entire on its own ground, whatever steps may have led us to it, any attempt to conform to dry ordinary facts as they meet us in the world would be idle, and, as an offence against art, censurable. If, on the contrary, his object were not to frame a society after an ideal in his own mind, but, as we have supposed all along, to investigate the conditions of political unity—the idea involved in the very existence of society by departing from which it has become confused and incoherent—if this be the view of the treatise, which is most consistent with the rest of Plato's philosophy, and which most clearly exhibits its relation to the other Dialogues, then it can be no matter of wonder to us that Plato should carefully abstain from any exercises of imagination while he is setting before us the bare and naked elements of which society is composed, that he should take pains to convince us that he is not a creator but a searcher; not one of those poets to whom he can assign no place in his commonwealth, but one of those investigators of the truth as it actually is whom he would put at the head of it.

The *Republic* of Plato then assumes selfish desires to exist, and the evil results of them to have occurred. And it is an examination of this question,—under what conditions can we suppose it permanently to cohere in spite of the tendencies to decomposition which manifestly discover themselves within it? When, however, we direct our attention to the means of preserving any body from decay, we may either consider what positive precautions are necessary in order to resist the progress of its corruption; or, on the other hand, by what means it is possible to call forth and invigorate those principles of life which it must have within it in order that it may be at all, though their presence may only make itself manifest through the power which opposes them. Plato again and again gives us to understand that it is with the development of these principles of life, and not with the outward regulations for the repression of evil, that he concerns himself in this dialogue. It is on this account that the *Republic* has assumed to many persons the appearance simply of a treatise on education, nay, of little more than a censure upon the existing Greek education. These persons remind us that he has scarcely given the first rude hint of his society before he tells us that the minds of the guardians of the state must not be corrupted by those false ideas of the gods which occur in the poems of Homer. That a great part of the third

losophy.

Moral and
Metaphy-
sical Phi-
losophy

book is occupied with the consideration of two particular branches of education, gymnastics and music, and even with a minute and elaborate inquiry respecting the kinds of music which serve or frustrate the ends of education. That the subject is renewed in the sixth and seventh books, where the use of all the sciences in forming the mind of a statesman is carefully investigated. All this is true, yet we are persuaded that the value of this portion of the work will be far more appreciated by those who consider it subordinate to the great object of discovering the principle which lies at the foundation of society, which connects it with the processes of the individual mind, and which gives consistency and harmony to both of them, than by those who determine that it shall be the sole and independent purpose of the dialogue. Nothing is more entirely consistent with the purpose which we have attributed to Plato than his placing a right view of the character of the gods at the threshold of his education; for the idea of the good, and of this as connected with order, is that which underlies his whole scheme. To make men feel that this *is*, that this exists, to teach them how to distinguish between the anomalies of society and its principles, is his great endeavour. Above all things, therefore, we must see that our models are not defaced with our own corruptions.

For precisely the same reason the subject of music becomes invested with so much importance. To develop the sense of order and harmony in the minds of the members of the commonwealth, is the secret for making it really that which it pretends to be. It is a part of this order that the feeling of it should be first communicated to the guiding, guarding minds of the society, that from them it should diffuse itself through the whole; and by this means a new and most important element of our *Republic* is brought to light. Among the guardians will be some of a higher order than the rest. They will be those on whom the education has produced its complete mellowing effect; distinguished from the others in this, that whereas *they* have chiefly derived a more braced and masculine tone of character from the union of gymnastic exercises with the higher forms of music, these have imbibed the very essence of the music, have acquired that perfectly harmonized temper, that sense of wholeness which makes them the true ideals and representatives of the entire community. These are obviously our *magistrates*. But how shall we persuade our people that these different qualities exist, and that they constitute a fitness for the different offices in the state? We must tell them a story, says Plato, in order that we may bring home this conviction to their minds. We must inform them that they were all made originally out of the earth, which, on that account, they are to love as their common mother; reckoning themselves brethren in consequence of their relation to her. That however it pleased the gods to introduce different materials into their composition, making some of gold, some of silver, some of inferior metals; that it is important that these should not be confounded, but should be kept distinct and applied to distinct uses, in order that the society may receive benefit from each of them. Such is the parable by which our author teaches us that he looks upon himself not as the contriver of some imaginary scheme, but only as following out the intentions of Providence in the institution of society.

All this time we seem to have been forgetting our original question respecting justice. But we find in the

fourth book that the arrangements of the state, and even our long discussion upon music, have been preparing the way for a more clear developement of this idea. We have discovered three classes in society, and we have seen that each of these classes embodies a certain characteristic quality, which through it becomes the quality of the whole fellowship. The class of magistrates expresses to us the very idea of wisdom, superintending, distinguishing, arranging; the class of guardians, the very idea of fortitude, sustaining, amalgamating, preserving; the inferior classes, while they keep their position, the very idea of temperance, self-restraining, and submitting. Without any of these it is obvious that a society could not exist, and the permanence of its existence depends upon the degree in which the qualities of each class interpenetrate the rest. But then does not this imply the existence of still another quality—of some principle of power which fuses together all the classes and all these qualities—which belongs not primarily or particularly to one class, but must by its very nature be predicated of the whole? This is evidently that musical principle which we have been seeking by all our education to instil. But what shall be the name of it? Is not this that Justice which we have been trying to understand the meaning of? Do we not translate the rude outward notion of Simonides into a real practical, satisfactory idea, when instead of making justice consist in giving every man his due and in speaking the truth, we describe it as that which determines the true relation of all things and persons to each other, the very law and harmony of the world. Yet may we not go still a little deeper? Our first object was to discover the nature and effect of justice, not in society, but in the individual. At every step of our progress we seem to have found proof that these two considerations are inseparable; that the law of society must be the law of the individual. Now, perhaps, we are in a condition to explain this fact more particularly. Our inquiry has brought to light three classes as the necessary constituents of the state; a class of magistrates, a class of guardians, a class occupied in supplying the animal wants of the whole body. Whence the necessity for this distribution of society? Is it not that there is a similar distribution of parts in the man himself? Is there not in him a reason, energy, or will, cupidity or an animal nature? And if these are not to exist in perpetual discord, the man in perpetual misery, must there not be that in him which preserves each of these apprehensions or tendencies in their proper relation to the rest, giving the supremacy to reason, preserving the strength and purity of will, subjecting cupidity? Is not justice then necessary to each of us?

This point being ascertained, Socrates is willing to finish the dialogue. But Glaucon and Adeimantus remind him that justice being according to him the principle of harmony or unity in the commonwealth he is bound to explain the other conditions of this unity. For if any inevitable circumstances make this union impracticable, justice itself is impracticable, and if for the commonwealth, then, according to the whole tenour of the argument, for the individual also; so that we should be obliged at last to acquiesce in a conclusion not very unlike that sophistical one which we have been labouring to confute. The four next books, then, from the beginning of the fifth to the end of the ninth, are occupied with these questions: first, in what sense are family relationships compatible with the unity of a commonwealth? secondly, how far can it consist with the individual sel-

losophy.

Moral and
Metaphy-
sical Phi-
losophy.

fishness and ambition? thirdly, how can it consist with that law of decay and degeneracy to which all societies seem to have been subject?

What Plato's statements are upon the first of these subjects we have no need to inform any reader. Those who know scarcely any thing else of him have heard that he has somewhere spoken of the two sexes as intended to perform exactly the same duties and exercises, and that he has connected with this doctrine another (which indeed in a logical mind will generally be inseparable from it) of a community in wives and children. They have heard also that these notions actually enter into the composition of his perfect commonwealth; and that he wishes to supersede all those existing relations of father and child, wife and husband, which we have described in the beginning of our sketch as lying at the foundation of all moral apprehensions and all political order. The question then naturally suggests itself, not whether we are prepared to offer any justification for this part of his speculations, but how, while such a huge and hideous blot exists in them, we can venture to speak of them as important; above all, can devote so much time to the examination of them? Many readers and admirers of Plato have dwelt with much satisfaction on the fact, that in the *Laws* (a later work undoubtedly than the *Republic*) he appears to have changed his views, and to recognise the sanctity of human relationships as they exist. We confess that we do not regard the passages referred to as a recantation. Even if Plato considered them so himself, (of which there is no proof,) we feel convinced that he would have relapsed into his former opinion, if he had again devoted himself to the task of studying the idea of a commonwealth. The *Laws*, it seems to us, are intended to explain the conditions under which any particular nation exists; whence proceeds the coercive power by which the evils of its members are restrained; how it is to be preserved as a distinct community. For this end Plato perceived the importance of distinct relationships; he could not help seeing that they lie at the very foundation of national life; that with the loss of them it would perish. The *Republic*, on the other hand, is not an inquiry respecting the conditions of a particular state. Phrases may occur in it again and again which seem to define this as its object; but others far more pregnant in their meaning, and oftentimes uttered unconsciously, show that another and grander aim was present to the mind of the writer, and was haunting him when he could not realize it. He felt that there should be some body which expresses not the law of a confined, definite, national life, but the law of society itself, the principle of its unity. He felt that such a body as this is implied in the existence of every national community, but yet transcends it, and is not subject to its limitations. We could easily produce proofs of this feeling from every book of the *Republic*, but we know none in which it comes forth more strikingly than in that fifth book of which we are now speaking. The idea of a universal Greek society is there formally put forth, yet it is evident that this does not satisfy the mind of Plato; he has the dream of something still more comprehensive: a feeble sophist would have tried to express the dream in big words; he is content to suggest the nearest practical approximation to an expression of it that his circumstances made possible. But with this universal society Plato does not see how distinct relationships are compatible. Perfect community seems the very law of its being; whatsoever interferes with

this seems to frustrate its intention. Here then we see at once the ignorance and knowledge of Plato. How such an universal society as this could grow out of a national community, out of a family, and could preserve uninjured, in harmony with itself, both those holy institutions which had been its cradle, this he did not know; this wisdom was reserved for the shepherds of Palestine. To them it was only communicated by degrees, and their chief duty consisted in keeping that which had been divinely given them in the sure confidence that more would be added. But this *was* permitted to the sage of Greece; he was allowed to feel the necessity of a universal community to the life of man. He was permitted to feel that it was a great living truth implied in the existence of society, though yet undeveloped. To such insight and honesty of purpose, rejecting no light that has been vouchsafed, it is granted that even the crudities and ignorances into which it falls in the search after truth shall be for the benefit of future generations, nay for the practical correction and exposure of these very crudities when they are reproduced by men of a different spirit. The fifth book of the *Republic* is a curious anticipation of every scheme of universal society which has been propounded by religious fanatics or political theorists from the propagation of Christianity to the present day. It remains a standing practical testimony from the wisest man in the ancient world, that this is the only consistent law, and must be the ultimate law of every such society, whensoever it attempts to exist alone, as a merely spiritual or cosmical family. Rejecting then with indignation the *errare mehercule malo* of the Roman academician, and follow Plato only so far as he loved truth, we may yet find a worth even in this unfortunate passage of his writings.

The portion of the *Republic* comprehended in the sixth and seventh books is second to no part of it in interest. The difficulty to be solved in it is the compatibility of such a state as we have described with the selfish notions of men. Plato does not blink the question. He at once declares his conviction that such a state could only be administered by philosophers; and he then goes on to explain what he means by a philosopher; why it is that the persons generally bearing that name are unfit to be practical politicians; what their real relation as to the rest of their countrymen is. Here then we have the full exposition and developement of that doctrine which we found lying at the root of Socratic teaching; that the selfish self-seeking principle leading men to animal gratifications is the source of disorder and confusion in the life of man, not really the moving spring of it; that there is in man something higher which is not satisfied with itself, but which seeks after converse with the good. The philosopher is the man who is holding this converse; whose mind is fixed on the true end and meaning of things, upon the substance—the reality of them. The rest are following images and shadows, but still in the pursuit of these are confessing their want of a good, and are blindly feeling after it. The philosopher, if he descends to the pursuit of their shadows, becomes worthy of their contempt, for there is a perpetual contradiction between the higher aims of which he is conscious and the grovelling course he has actually taken. If, on the other hand, he steadily keeps his own idea in sight, he is necessarily unintelligible to them, and on that account they despise him. But suppose, having worked his own way out of the mine in which they are dwelling, and no longer receiving light

losophy.

through the little crannies which transmit it broken and confused, and lead men utterly astray as to the fountain from which it has flowed, he has come out into the open sunlight, and by it seen all objects as they are, he neither glorifies himself by living apart from them, nor yet submits to confuse his light with their darkness, but goes down amongst them that he may lead them by the same track which he has himself trodden into the clear day. Would he not then be filling his function as a philosopher and yet be most truly a politician? If the question occurs to you, what is this upward road? Plato is ready to consider it with you. There is a certain education recognised among men; they teach arithmetic, geometry, as well as the gymnastics and music, we spoke of before, and they evidently attach a high value to these studies. Are they wrong? surely not. They are wrong only in this that, throughout their whole lives, they are seeking shadows instead of substances, and that they have made all these sciences helpful to their low ambition. Arithmetic and geometry have been resorted to merely for secular commercial ends; they might be made the means of purifying the mind to a perception of the truth of things. What is the appropriate function of each of these sciences, with a view to this object, he carefully inquires: and this inquiry brings out the necessity of that grand, deeper science of dialectics, which directly leads to the contemplation of truth as truth, of good as good, in its pure essence. Now a nation thus guided and educated comes into the condition of such a republic as we have described. Its wisest, deepest minded men will become its magistrates; the community will have one end; that principle of justice, which assigns to each his proper place, imparts a sense of proportion and harmony to all, will be diffused through it and actuate it. Thus, then, the existence of ambition and selfishness does not upset the idea of our republic, does not prove that it is not implied in the nature of society, does not show that it may not be at some time or some where realized.

We come next to that law of decay in societies which most speculators have recognised, and which the Pythagorean philosophers fancied they could express in certain numerical ratios. Plato has given a very valuable turn to the inquiry by connecting it with the cardinal doctrine of the *Republic*, that the life of men and the life of states explain each other. In conformity with this doctrine, he maintains that there is a democratical, an oligarchical, and a tyrannical form of character answering to those respective forms of government. This form of character is obviously a departure from some true and original model. The same may be shown of the governments; and it is possible in each case to trace the process of degeneration, and to show how that which takes place in society, and that which takes place in the individual, react upon each other. In this part of the dialogue Plato proves that his faculty of close, lively, practical observation had not been impaired but strengthened by his converse with transcendent realities. It would be hard to find a passage in any ancient work on which a modern statesman might more profitably meditate, or in which he would be more sure to find hints explaining to him the facts of his daily experience, than the eighth and ninth books of the *Republic*. The result of the investigation is the same as in the former case. This law of degeneracy exists in the commonwealths of the earth, just because they have not understood and steadfastly contemplated that original model,

that perfect idea of a commonwealth, which is also the original model and perfect idea of a human character. It is a contradiction and absurdity then to allege the fact of this degeneracy as a proof that no such model is to be found. But after all these inquiries does the thought still linger about the mind, where is it to be found? Plato answers, (book ix. p. fin.) ΑΛΛ' ἐν οὐρανῷ ἴσως παράδειγμα ἀνάκειται τῷ βουλομένῳ ὁρᾶν καὶ ὁρῶντι ἑαυτὸν κατοικίειν. Is it wonderful that such words should have suggested to some of the Christian fathers the recollection of those words in the *Epistle to the Hebrews*, which describe the hopes of the head of the covenanted people, Εξεδέχετο γὰρ τὴν τοῦς θεμελίους ἔχουσαν πόλιν ἧς τεχνίτης καὶ δημιουργὸς ὁ Θεός: or those which describe this hope as accomplished, Ἡ πολιτεία ἡμῶν ἐν τοῖς οὐρανοῖς?

There is still one subject upon which it is needful to say a few words, especially as Plato has devoted his last book to the full exposition of it, we mean his opinion respecting the imitative arts generally, and especially of poetry, so far as it is included among those arts. It is evident that our author attached great importance to these opinions, and yet that he was never wholly satisfied with them. He touches upon the question almost as soon as he has sketched the first outline of his society; he recurs to it again when his task seems completed, partly as if he felt there was no security for the reception of his idea while any doubt overhung this point; partly as if there was something in it which he had not fully penetrated. Again, in the introduction to the *Timæus*, he offers a kind of apology to the poets for his severity, and appears to think that they may have an important vocation, though he does not clearly understand what it is. It is observable that the grounds upon which he places his arguments in the third and in the tenth books, are not precisely the same. In both, indeed, he dwells much upon the fact that the poet must adapt himself to the opinions of mankind respecting actions and character, otherwise they will not acknowledge the verisimilitude of his picture; hence he must need pervert the truth of things, and can never exalt those minds to which he accommodates himself. But in the last he appears to see a peculiar mischief in poetry from its tendency to destroy the harmony of character, to weaken self-control, and thus to undermine the justice and order of the commonwealth by the honour which it bestows upon all excited and passionate feelings. The latter argument might lead one to suspect that Plato was at least in part determined to these views by the circumstances of his own age. The exaltation of passion, the want of balance and harmony in characters, the preference of weak, earthly creatures to calm and stately ideals, were the great characteristics of the Euripidean, as distinguished from the Sophoclean drama. Add to this the influence of a poetical age (an influence felt most when that age had departed) in fostering the worship of mere creative power, and the notion of the mind of man being the origin of all that is, which lay, as we have seen, at the root of all Greek sophistry, and which it had been the great aim of Socrates throughout his life to combat. Still Plato's attack upon Homer, and his eagerness to disprove the common opinion that the Greeks were really indebted to him for much of their organization and cultivation, are proofs, we think, that he was not merely affected by these temporary considerations. We leave it then as a hint for our reader's reflection, whether this reluctant condemnation of poetry by one who had been

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphysical
Philosophy.

himself a poet in the formal sense of the word, and in the best sense continued a poet always, may not be explained in the same way as we explained just now his theory respecting relationship. In an early part of our sketch we remarked that poetry seemed to belong primarily and almost exclusively to national life. The sense of national union gives the first impulse to it; when that sense is weakened it withers, with its revival it starts to life again; without it men would never become conscious of their own powers, their own affections, their own wants; and in the consciousness of these consists the joy and freedom of their life as the citizens of a state. By calling this forth in the Greeks, Homer may be said to have made them a nation, a nation full of life, full of turbulence. But is there nothing higher than this mere consciousness of power? Is there no higher condition of society than this of being citizens of a state? The *Republic* is an answer to the question. It teaches that far beyond this consciousness of power lies the contemplation of truth and goodness, and the assimilation of the soul to these. It shows that far beyond the mere feeling of energy to dare, to act, to revenge, lies the perception of order and harmony, and intimate fellowship with a Being above us, and the beings around us. It teaches that there is a universal society, of which this contemplation and assimilation are the ground, this perception of order and harmony the life, of which this fellowship is the result and the realization. With this community, says Plato, poetry hath little to do. Praise of the gods, eulogies of great men, these are the only fields for its exercise. Strictly speaking, we think he is right, that is to say, if it were possible for us, as it was necessary for him, to separate (how important it is to distinguish we hope we have explained) the national life from the universal life, the national society from the universal, poetry, which is the soul of the first, would, except in the cases named by him, be excluded from the other. If we would connect all the vital energies of which poetry is the expression, with those deeper insights, that perfect moral state and moral life which belong to the higher region, we must also understand, and by understanding realize for ourselves at least, and so far as is permitted us for mankind, the law by which the universal and the national society sustain each other.

The *Republic* ends nobly with a discussion on immortality, which has been less popular than that in the *Phædo*, because the scenery of it is less solemn and affecting, but which for its own merits seems entitled to even more attention. We are far indeed from thinking so lightly as some have done of these arguments from reminiscence, and from the law of interchange between light and darkness, death and life, which occur in the dying conversation of Socrates. On the contrary, they seem to us pregnant with the deepest meaning. But we cannot help thinking that when Plato had once realized in his own mind the connection between the life of the individual and the life of society, he felt he had a stronger ground to fix his hope of immortality upon—that he had found the point where the witness in the heart meets the demands of the reason. The sense of belonging to a community, stretching behind and before, outlasting the deaths of generations of men, is an evidence to each man of his individual immortality, which you may be quite unable to translate into syllogisms, but which happily supersedes the necessity of them. Plato only went to the roots of this feeling, when,

having shown that the existence of the individual and of society are alike based upon the idea of justice, and are alike sustained by the contemplation of that which is true and permanent, and alike die a moral death when they contradict the principles of their being, he affirmed that the accident of physical death can as little change the condition of one as of the other, and that as each has lived here must be his life hereafter.*

We have dwelt so long, for reasons which we have explained already, upon this great summary of the ethical, metaphysical, and political philosophy of Greece, that we can afford time but for one remark which is necessary in order to show how the doctrine of Plato is connected with that of the great predecessor whose labours we suppose that it was his intention to review. That there is a Pythagorean character in the *Republic*, the book on music, the passages on geometry and arithmetic, and certain mystical sentences respecting the law of decay in a state, which have defied the skill of commentators, abundantly prove. But if we look well at the work, we shall find that the whole of it may in one sense be called Pythagorean. For the discovery of the musical law which gives internal wholeness to a state, as distinguished from that external law by which its parts are prevented from falling asunder, is in fact the object of the treatise. Wherein then does he differ from Pythagoras? Precisely in this; that while he gives music and arithmetic their due honour as instruments for cultivating in man the feeling of his own position and relations, he does not deduce that position and those relations from any combinations of notes or series of numbers. He makes justice—a moral principle—the music of his commonwealth. And this is the more remarkable and the more honourable, because it is evident that he felt the temptation to be a cabbalist, and never divested himself of the belief (perhaps no deep thinker was ever able quite to divest himself of it) that there is something profoundly and mysteriously interwoven with the life of man in the relations of lines, of numbers, and

* As the *Republic*, like so many other of the Platonic Dialogues, closes with a mythus, and as the passage in the third book on Lying brings the whole subject of the use which Plato thought it lawful to make of fables and legends directly before us, it may be as well to make one remark on this subject. Throughout this dialogue, even more than in his other writings, it is evident that dearly as he loved truth for its own sake, and firmly as he believed it could be contemplated in its pure essence, he yet felt that there was no criterion of truth so sure as that it governed practice and was the law of life. To substitute a pure idealism for the faith of his country was never his object or his dream. He hated such attempts, not more for their hardness and cruelty than for their utter inconsistency with his whole doctrine. He left them to men who did not believe that ideas were substantial, who thought they were mere creations of the mind and had nothing to do with living acts. While then he was very jealous of all those stories which evidently hindered men from acknowledging goodness and truth as the ultimate ends of their existence, he was equally certain that somehow or other all great principles must have an investiture of facts, and cannot be fully or satisfactorily presented to man except in facts. And if no such series of facts embodying and revealing truths were within his reach, rather than leave it to be fancied that his truths are bare naked conceptions of his mind, he will invent a clothing for them: it is the least evil of the two. But it is an evil; it exposed him to fearful contradictions; it often puts his love for truth in the greatest jeopardy. Then what pretence have those to the name of Platonists who wish to believe that there is no series of facts containing a revelation of supersensual and transcendent truths, who think it an *a priori* probability that the deep want of such facts which Plato experienced has not been satisfied; who are determined even by the most violent treatment of historical evidence to prove that whenever a supposed fact manifests a principle, it must be a fable?

losophy.

of sounds. It was a great merit thus to keep the practical ground so steadily, and never to forget that this is really the highest ground. By doing so he was enabled to perform the same service in one sphere which he had already performed in another, to discover the political principle which Pythagoras had been seeking for amidst the influences that connect us with nature, as he had discerned the scientific principle which Parmenides had been groping after amidst the forms of our own minds.

It is a great satisfaction to us that our duty, as historians of moral and metaphysical inquiries, does not call upon us, or even permit us, to say many words on the subject of Plato's *Physics*. Still the *Timæus* is so curiously connected with the *Republic* by the exquisite introduction to it, in which Critias tells the story of the submerged state, so like in all respects to that which Socrates had described the day before, (here we have the doctrine of reminiscence obviously brought into play, and a new evidence that our philosopher considered the *Republic* as no work of imagination, but the discovery of a truth implied and forgotten in the constitution of all societies,) and so much importance has been attached both in early and later times to this dialogue, as if it contained the very heart of Platonism, that we cannot venture entirely to pass it over. With respect to the link between the *Politics* and the *Physics* of Plato, we would not speak confidently. He may have perceived a closer relation between the moral *κοσμος*, which he had been investigating in the *Republic*, and the material universe which *Timæus* creates, than we are able to trace. But this we think is evident, that he did enter upon his new task with a kind of consciousness that it behoved him to fill up a gap in his speculations and to complete his review of the ancient philosophy, and at the same time with a secret apprehension that the light which had hitherto guided him might forsake him in this region. It is strange at all events that, while undertaking to develop a subject so important in Greek eyes as the creation and organization of nature, he should make Socrates a merely listener. To a faithful student of Plato it must still seem more strange that he should on this occasion utterly desert his customary method, that the dialogue form should be merely used to throw a graceful dramatical veil over the introduction, and that in the expository part it should be exchanged for the haranguing style to which Plato was in general so averse. And yet it is to this cause more than any other that the *Timæus* owes its reputation among those who undertake to furnish summaries and synopses of Platonic doctrine. Elsewhere they found him balancing opinions, often refusing to pronounce a verdict upon their respective merits—most unnecessarily tedious (as they think) in tracing the road to a conclusion, most unaccountably and ill-naturedly forgetful of the duty of clothing it in precise, available, transferable formulas. Here on the contrary, though his language may be more obscure than it is in other places, though there may be more allusions to ill-understood portions of Greek speculation than in all the rest, though, lastly, his teachings refer to a question upon which we all believe that he could have only very partial illumination; still the manifest convenience of catching so Protean a philosopher for one moment in a rigid definite state, has outweighed all these considerations, and has made the Platonic cosmogony the grand storehouse from which diligent redactors have been wont to collect their notions of the mind and the works of Plato. Nay it has even been a plausible and popular

theory, ingeniously accounting for the uncertainty of the other Dialogues, that they were only intended as a vestibule, to the inner oracle of the *Timæus*. Having sufficiently explained our views respecting these so-called uncertainties, and having endeavoured to show how much the method of Plato is part and parcel of Plato himself, we must needs regard this particular work with very different feelings. Not pretending to behold with indifference the splendid theory which it develops, aware how closely that theory is connected with some of those which exercised the strongest influence upon the minds of men, especially in the first ages of the Christian Church, and being very willing to accept for Plato the compliments which natural philosophers have paid him for his intuition of truths hereafter to be established, we must yet confess that the *Timæus* seems to us chiefly valuable because it illustrates the worth of the principle from which it is so signal a departure. In every other dialogue Plato is teaching us how to discover a universal law in any particular fact which falls under our notice; here we have huge hypotheses to begin with, and all facts fitted and disposed according to them. For whatever there is of truth in these hypotheses he is indebted to his previous studies in another direction. Having arrived by his own sure course of upward investigation at the doctrine of ideas, he was able to see that the world must be created according to an idea. But having attained this point, his light forsook him, he was not able to apply his dialectic to the elimination of this idea, from the names or facts in which it was imbedded. He had simply to trust to his imagination to construct a theory. Whereas in other cases he is a philosopher seeking for light, and when he could not perceive the track of it, showing where it ought to be, and from what unrisen sun it must flow, here he is a presumptuous theologian, assuming himself capable of declaring that which must be revealed, and thereby losing the right way to that which may be discovered. Bacon does him no injustice in respect to his *Physics* when he says that he confused and corrupted them with theology, when he implicitly includes him among the giants who piled hill on hill in hopes of reaching heaven. Would that our countryman, for the honour of his own character, for the sake of the ages which were to follow him, had been as willing to recognise the truth of Plato, as he was acute in detecting his falsehood; as honest in acknowledging him for a guide, as he was right in pointing him out for a beacon. He would then have seen that the *Timæus* was in contradiction to the principle of induction, because it was inconsistent with the principle of Plato. He would have seen that in one solitary instance the Greek sage was betrayed by that ambition of completeness and circularity (which far more than the desire of fame deserves to be called the last infirmity of noble minds) into the examination of a subject on which he only could dogmatize, and could dogmatize only by forsaking his own method. He would have confessed that the *Novum Organum* was but the extension of that method to a new class of subjects. He would have taught his disciples that the course of investigation which promised them such new discoveries in the world of sense, which was grounded upon the great principle that man is but a seeker after that which really exists, which is prosperous in proportion as they endeavour simply to behold that which is, and not to darken it by the mists of his own conceptions, had been ages before marked out as the only one by which they may safely hope to become acquainted

sical Phi-
losophy.

with the truths of their own being. He would solemnly have conjured them to remember that a heathen, uninstructed by that revelation which deals directly with these transcendent truths and lays them open to every peasant, had yet perceived that they must be the most precious which a man can know, and that only in knowing them he is truly a man. He would have told them, that if ever that study, in which the heathen sage forgot his usual wisdom, should become the only one in which Christians care to be proficient, if ever *ex reseratione viarum sensus et accensione majore luminis nature aliquid incredulitatis et noctis animis nostris erga divina mysteria oboriatur*—or there should grow up a feeling towards these mysteries which is worse than unbelief, or else another form of it, a stupid acquiescence in them without the acknowledgment that they answer to any cravings in the heart, any necessities of the reason, any predictions of the imagination, then for the sake of the age and country upon which such a disease had fallen, for the sake of all that should follow it, for the sake of physical knowledge itself, which can never long flourish apart from moral light, it would be most desirable that men should resume the study of the Athenian philosopher, should realize the wants of their minds by observing those which he experienced in his should consider in what way we can find an adequate provision for both.

*Aristotle.**

Aristotle.
External
difference
between
him and
Plato.

A student passing from the works of Plato to those of Aristotle is struck first of all with the entire absence of that dramatic form and that dramatic feeling with which he has become familiar. The living human beings with whom he has conversed have passed away. Protagoras, and Prodicus, and Hippias, are no longer lounging upon their couches amidst groups of admiring pupils; we have no walks along the wall of the city, no readings besides the Ilissus, no lively symposia giving occasion to high discourses about love, no Critias recalling the stories he had heard in the days of his youth, before he became a tyrant of ancient and glorious republics; above all, no Socrates forming a centre to these various groups, while yet he stands out clear and distinct in his individual character, showing that the most subtle of dialecticians may be the most thoroughly humorous and humane of men. Some little sorrow for the loss of so many clear and beautiful pictures will be felt by perhaps every one. But by far the greater portion of readers will believe that they have an ample compensation in the precision and philosophical dignity of the treatise for the richness and variety of the dialogue. To hear solemn questions treated solemnly, to hear opinions calmly discussed without the interruption of personalities; above all, to have a profound and considerate judge, able, and not unwilling, to pronounce a positive decision upon the evidence before him; this they think a great advantage, and this, and far more than this, they expect, not wrongly, to find in Aristotle.

Still we are of opinion that a person who is able to render justice to the method of the master, will, on the

* It may be as well to remind the reader that two elaborate lives of Socrates and Plato appeared many years ago in this ENCYCLOPEDIA, and that one of Aristotle has lately been added to them. The author of this article has therefore no excuse for dwelling upon any particulars of their history, not directly tending to the elucidation of their doctrines.

whole, be the most likely to appreciate the disciple; at all events we shall not understand either well if we content ourselves with a vague notion that one was a consummate artist, the other a profound practical philosopher. That Plato did not adopt his dialogue form for any artistical purpose, but simply because it was necessary for the developement of his idea of science, we have contended already. And we feel it equally necessary, in order that we may claim for Aristotle the true and very noble position which of right belongs to him, not to let it be supposed that his pretensions to be either practical or profound rest upon his want of those qualities, and his abandonment of that method by which Plato is distinguished. In common parlance we are wont to consider those most practical whose studies are most connected with real, living, passing questions. Now it was the actual opposition of sophists, which drove Socrates and Plato to seek for principles not yet recognized, lest they should lose those which they had. Aristotle had the advantage of being able calmly to examine sophistical arguments, because it was the hour in the school for that particular subject to be lectured upon. It was a question of life and death in Plato's day, whether we have something permanent to rest on or no; for men in every town of Greece were abusing the name of Heraclitus in support of the doctrine of a perpetual flux. Aristotle could label this question physical or metaphysical, and patiently balance it against some opposite theory. The Parmenideans forced Plato to investigate the nature and conditions of science, for they threatened it with a hopeless stationariness. Aristotle is under no such alarm; he has merely to make out a system of analytics. It was because the Body of Socrates was about to pass through death, that he was led to consider the meaning, and nature, and enduring properties of the Soul. Aristotle begins his treatise on the same subject, with inquiring whether the subject is to be considered in reference to any particular person at all or abstractedly, and whether we are to speak of it physically or dialectically. Without determining which of the two courses we have indicated is the best, we think it must be a violence upon ordinary usage to say that the latter is the more practical. Neither is the quality of depth precisely that one which we conceive ought to be predicated of Aristotle, when it is our object to contrast him with his predecessor. It was the necessary consequence of Plato's situation and of the task which had been committed to him, that he was always seeking for principles—for a foundation to rest upon. The most simple every-day facts interested and puzzled him; nothing that human beings were interested in was beneath his attention; but then it was the meaning of these things, the truth implied in them, which he was continually inquiring after. He found the commonest word that men speak, the commonest act that men do, unintelligible, except by the light which comes from another region than that in which they are habitually dwelling. Of this feeling there are no traces in Aristotle. To collect all possible facts, to arrange and classify them, was his ambition and perhaps his appointed function: no one is less tempted to suspect any deep meaning in facts, or to grope after it. In like manner to get words pressed and settled into a definition is his highest aim; the thought that there is a life in words, that they are connected with the life in us, and may lead at all to the interpretation of its marvels, never was admitted into his mind, or at least never tarried there. In this disposition there may be a comfort and an advantage; but it certainly

is not that upon which persons who are careful in the use of language could bestow the epithet *profound*.

Another prejudice in reference to these great men it is necessary to remove, or we shall not understand their relative positions. It is often fancied, and Aristotle seems not altogether anxious to do away the impression, that Plato's disciple forsook him when he forsook his master; that the later philosophy is in some important respects a return to the simple faith of Socrates. If what we have just said be correct, this notion must be not only wide of the truth but in direct contradiction to it. The personality of Plato was precisely that quality of his mind and of his writings which he had inherited from Socrates. That he so seldom deviated into abstractions; that he preserved so strongly the feeling, we are actual men, wrestling against evil tendencies within, and evil powers without, capable of being educated, and of educating each other into a longing after, and perception of, the perfect goodness and truth, this he owed to Socrates. His own especial work was to connect this personal struggle with the orderly developement of principles. It was precisely then with the Socrates in Plato that Aristotle was incapable of feeling sympathy. That he had a general reverence for his good sense, that he recognized him as the useful and victorious opposer of what was mischievous and unphilosophical, and that he sincerely believed him not to have held certain offensive opinions of his disciple; this we can easily imagine. But that he the least admired the Socratic method, or that all his wisdom could avail to teach him into what conclusions that method must necessarily lead one who habitually followed it, we cannot believe.

His
alleged
jealousy of
Plato.

Though these remarks seem for a moment derogatory to the fame of this wonderful man, they will be found upon reflection to relieve his character from some unjust imputations, to set his actual merits in a clearer light, and to explain the kind of influence which he has exerted, and must always exert over mankind. There are passages in his works which, in the opinion of some over watchful and sensitive critics, indicate a personal jealousy and dislike of Plato. They remark that he does not introduce his comments upon him in a manly, philosophical spirit, but generally with some of those affected phrases of reluctance which display often more than the strongest vituperation the ill will that is lurking within. Possibly far less meaning would have been seen in these passages, if the gossiping anecdote-mongers of later Greece had not illustrated them by stories of dissensions between the master and the pupil, which, though obviously derived from a very vulgar invention or a memory generally treacherous, because always trivial, still unconsciously influence our minds when we have once heard them, and prevent us from fairly looking at the evidence which gives them their only plausibility. Separated from these stories, the quotations we think prove no more than that Aristotle felt a certain irritation and displeasure when he perceived there was something in the words of Plato, which his large intellect and immense information did not enable him to comprehend. To be continually haunted with a consciousness of this kind, in all definable qualities I am equal, nay superior to my predecessor, I have reduced subjects into far greater order; I analyze far more perfectly, I have a far greater store of facts at my command, and yet there is in him something quite *undefinable*, which seems to make an incredible difference between us; this may have been no doubt very vexatious

even to an honest and great mind. For it was not merely the personal humiliation of such a reflection which would be grievous to him, it would jar against the strongest feeling of his mind that nothing ought to be incapable of definition, and that whatsoever does defy it can scarcely be of any great worth. While then it is no doubt possible that petty quarrels may have been stirred up between two such men by admirers and flatterers, who were equally incapable of understanding either, we have no need of that supposition to account for the sneers and taunts (if such they must be called) which now and then displease us in Aristotle. We shall fully explain these to ourselves when we consider the characters of the men, and connect them with the characters of their times. This last point is of more importance than we are at first inclined to fancy. When we think of Aristotle as the disciple of Plato, we group them together as if they belonged to the same portion of Greek history. But when we acknowledge Plato in his true character, as the expounder of Socrates, we feel at once that the age which bore the name of Pericles, but may really be said to date from the Persian war, was the one which he was appointed to adorn. This was an age of individual energy, when pregnant events were transacted in insignificant localities; when the lowest party-contests were developing the most universal and permanent principles. That which was followed was an age of concentrated, organised power, of successful assaults upon freedom, of grand conceptions, of extensive conquests, of what has been well called *material* sublimity. Of such an age Aristotle was, we believe, a more perfect representative than Alexander.

In conformity with these remarks it will not be difficult to show wherein the peculiarity of the Stagirite philosophy consisted; how it grew out of the Platonic, how far they are contradictory, how far one occupies a space which the other had left void. We have seen by what steps Plato was led into his high estimate of Dialectics. He watched his master maintaining a safe moral position against the attacks of the sophists. To assert realities against appearances and counterfeits was his single aim. Keeping this steadily before him, he almost unconsciously wrought out a method entirely different from that of previous philosophers. As Plato reflected upon the end which Socrates had proposed to himself, he perceived the full practical meaning of that truth which in terms had been asserted by Xenophanes and others, that Being is the object of all our inquiries. He saw at the same time how necessary it was to connect the end with the method; for till that method had been practised, Being had been a word, a notion, a negation; not an object to be really beheld and striven after. Hence the immense importance of bringing that method forward; of presenting it substantively, as it were, to his pupils; not allowing them *merely* to contemplate it as leading to certain results, but as the safe and universal means of arriving at any results. We have alluded to a class of dialogues having this purpose; and these, or something answering to them, (*approaching*, it is possible, the nature of ordinary exposition, though we can scarcely believe that Plato ever abandoned the dialogue as his vehicle of instruction,) must have been the peculiar study of the academy, as such, and expressly of the more advanced disciples.*

* In the *Life of Aristotle*, published in this *ENCYCLOPEDIA*, it has been shown, we think most satisfactorily, that the *acroa-*

Hence there will have grown up among these pupils a feeling respecting dialectics which Plato would have been anxious to discourage, and yet which his own works continually tended to foster. Seeing it used as a key to unlock the secrets of social life, of moral life, of physical life, and seeing, likewise, the pains which their master took that they should examine the wards of the key, it was most natural that they should think a much fuller and more systematic developement of this all-important science was desirable and even necessary. It would occur to them that there was something like confusion and irregularity in the proceedings of their great teacher. Had he not strangely mixed together inquiries respecting the grounds of morality with statements respecting the nature of science? Surely it would have been much better, much more orderly, that these questions should have been kept distinct and referred to particular heads. And were there not also some indications of narrowness in Plato, which a more accurate habit of distinction would have delivered him from? Had not his aversion to some of the usual abuses of rhetoric led him to undervalue the whole art, when it was undoubtedly capable, like every other, of being reduced to strict laws, and must deserve to be contemplated without any reference to its accidental results? The same might be said of his doctrine respecting poetry; the same, still more strongly, of his ill-concealed indifference to physical speculations. If all these subjects could be directly looked at in themselves as distinct branches of human culture, how much increase of knowledge might be expected in each, how much increase of clearness respecting the capacities and limitations of the human intellect! Such thoughts, we suppose, may have been at work in the minds of many who frequented the school of Plato. In few they will have borne any fruit, in most of these few the unripe or blighted fruit of some feeble theories, professing to universalize the system of Plato, really proving that their authors knew nothing either of Plato or of themselves. But there was one who was able to make the thoughts of the rest intelligible. To him Platonism will have appeared a needful preparation for a complete and circular philosophy. Its unsystematic character, its imaginative flights, its disregard of certain provinces of thought, will have seemed to him indications of rudeness and infancy. And he will have conceived the thought of assigning to each study its true position, that one which Plato declared and proved to be so important, occupying the first place, being exhibited in its full proportions, and determining the character and treatment of the rest. Dialectics, then, was in some sense the centre of both philosophies. Nor would it be correct to say that Aristotle consciously altered the signification which the word dialectics had borne in the discourses of his predecessor. He only wished to give the study more distinctness and prominence, to exhibit the processes and operations of which it treated apart from any particular applications and results. But in fulfilling this desire, the character of the pursuit became inevitably changed. The feeling of Plato was, There are certain objects presented to my mind; they may be sensible objects,

as trees; they may be objects for the understanding merely, as names; but objects they are still; things thrown in my way, and I must know what they mean; I must find out the truth of them. For this end I must have dialectics. The object has vanished from before the eyes and mind of Aristotle; he has begun to devote the whole energy of his mind to the contemplation of dialectics in themselves. What is the consequence? The sense of requiring them as the means of escape from the impositions which intercept our views of things as they are, becomes more and more weakened, till at last it disappears altogether. That principle which it had been the business of Plato's life to assert against Protagoras and his school, that the mind is not its own standard, that the aspects under which objects present themselves to us, do not constitute our knowledge of them, but that we may arrive at an acquaintance with them as they are in themselves; this principle, which had given his dialectics all their meaning, is no longer felt with any potency by his disciple. On the contrary, it is precisely the aspects under which we see and judge of things that he proposes to investigate. He wants to know what are the rules and conditions under which the mind, by its own constitution, considers and discourses. He makes the mind a centre, referring every thing to itself, just as those did with whom Plato contended. But he differed from them in this, that their intention was knavish, his most honest. They set up the doctrine that all things are merely as they seem to us, for the purpose of unsettling all faith, and proving the judgment of each individual to be a lawful standard. He sought to convince men that all is not unstable and fluctuating, by showing them that there is a fixed rule to which human judgments must conform, which limits the exercises of individual taste and caprice, which tests and reduces to order those appearances which the sophist pretended were infinite.

From this statement it will be easily apparent that the definition of dialectics in Plato and Aristotle may be almost the same, and yet that the whole scope and object of the science indicated by this common definition will be different. One as much as the other could say, Dialectics is that science which discovers the difference between the false and the true. But the false in Plato is the semblance which any object presents to the sensualized mind, the true the very substance and meaning of that object. The false in Aristotle is a wrong *affirmation* concerning any matter whereof the mind takes cognizance; the true, a right *affirmation* concerning the same matter. Hence the dialectics of the one treats of the way whereby we obtain to a clear and vital perception of things; the dialectics of the other treats of the way in which we discourse of things. Words to the one are the means whereby we ascend to an apprehension of realities of which there are no sensible exponents. Words to the other are the formulas wherein we set forth our notions and judgments. The one desires to ascertain of what hidden meaning the word is an index; the other desires to prevent the word from transgressing certain boundaries which he has fixed for it. Hence it happened that the sense and leading maxim of Plato's philosophy became not only more distasteful, but positively more unintelligible to his wisest disciple, than to many who had never studied in the academy, or who had set themselves in direct opposition to it. When Aristotle had matured his system of dialectics, there was something in it so perfect and satis-

matic treatises of Aristotle differed from the *exoteric*, not in the abstruseness or mysteriousness of their subject-matter, but in this, that the one formed part of a course or system, while the others were casual discussions or lectures on a particular thesis. The remark in the text is an extension and adaptation of this doctrine to the case of Plato.

pleteness.

factory, that he could not even dream of any thing lying out of its circle, and incapable of being brought under its rules. He felt that he had discovered all the forms under which it is possible to set down any proposition in words, and what there could be besides this, what opening there could be for another region entirely out of the government of these forms, he had no conception. At any rate, if there were such a one, it must be a vague uninhabited world. To suppose it peopled with other and those most real and distinct forms was the extravagance of philosophical delirium. Accordingly, when he speaks of the doctrine of substantial ideas, of ideas, that is to say, which are the grounds of all our forms of thought, and consequently cannot be subject to them, he is reduced to the strange, and for so consummate a logician most disagreeable, necessity of begging the whole question, of arguing that, since these ideas ought to be included under some of the ascertained conditions of logic, and by the hypothesis are not included under any, they must be fictitious.

As we proceed we shall have occasion to notice how this primary difference affected the views of these philosophers upon all questions which came under their notice. At present we speak of it, in order to show that the methods having a perfectly distinct object, do not of necessity interfere with each other; that the Platonic doctrine is not absurd, because Aristotle could find no place for it in his system; that the labours of Aristotle are not useless or ill directed, because they do not supply, as he fancied they did, any satisfaction to the inquiries which Plato had awakened.

Every orderly examination of Aristotle must then, we conceive, take its start from his treatises on logic. That these are not the most interesting of the works which he has bequeathed to the world we may easily admit, but, unless something is understood of their nature and purpose, it is scarcely possible to understand the character, the value, and the necessary limitations of his opinions on ethics, on politics, on rhetoric, on poetry. We shall presently quote the opinion of an eminent writer on physical science, to prove that a just estimate of Aristotle's labours in that department depends upon our knowledge of the importance which he attached to the forms of logic. And the settlement of the long debated question which falls more within the province of this article, what precise meaning he attached to the word Metaphysics, or what portion of his thoughts his disciples referred to under that name, can, we think, be hoped for only from a previous understanding of the connection in his mind between the idea of science and that of dialectics.

In the Berlin edition of Aristotle, the *Categories* occupy the first place. Some doubt has been entertained respecting the genuineness of this treatise, which modern inquiries appear to have removed. It would in many cases afford a reasonable ground of suspicion against a work, that it exactly filled up a gap in a set of acknowledged works by the same author, so that with it they form a complete system of instruction upon the subject which they treat. But it is a set-off against this consideration, that roundness and completeness are the great characteristics of Aristotle, and that it is less hard to imagine how a perfect series of his logical writings can have come down to us, than to believe any pupil capable of supplying a void that he had left in it. The difficulty, too, of supposing one man to possess the full mastery of this subject, which is indicated by the succes-

sive works which he has left, is diminished when we remember that the original conception of the study was not his, but Zeno's. How naturally that conception arose in a mind which had once entered into the great principle of Xenophanes and Parmenides, that the mind has laws of its own, and is independent on the appearances and determinations of the senses, we have explained already. What more than this discovery, and the application of it in confuting sensible conclusions, may be owing to Zeno, we do not know. It is not impossible that some of the sophists, while they turned the art to the worst purposes, may have yet done something for the refinement and improvement of it. In the school of Euclides not only the practice but the principles of logic must have been studied and elucidated. With these materials to work upon, it seems nowise incredible that one trained in the school of Plato to the greatest subtlety and precision of thought, and possessing in himself a comprehension and a diligence quite unparalleled, should have been able so to produce a design and an edifice which after ages have found it scarcely possible in the minutest particular to alter or amend. He had not to raise a science from its foundations, but *lateritium invenit marmoream reliquit*, may perhaps be said of him with as strict truth as of almost any architect that the world has seen.

Now the work on the *Categories* seems to be a most fitting vestibule to this building. On entering it we feel at once that the purpose to which it is consecrated is altogether different from that which Plato has been teaching us to regard as all important, and we feel that it is a true purpose still. There is a way of penetrating into the nature and essence of things, whether those which present an outward image to my senses, or those, equally real, which merely utter themselves to my mind. With this way Aristotle does not concern himself. But it is equally certain that our mind does form notions and conceptions about the things belonging to both these kinds which it contemplates, and it may be that these conceptions themselves are subject to certain rules. They may be defined and classified; there may be a general set of conceptions to which all particular conceptions will refer themselves. This Aristotle affirms to be the case. Under the ten notions of Substance, Quantity, Quality, Relation, Time, Place, Position, Possession, Action, Passion, he says you may reduce all your notions. Now a Platonist is very likely to ask, But what do these words, Substance, Quantity, &c., themselves signify? "How do I know what Substance is, better than I know what a man or a horse is?" "Quantity better than I know what three cubits long is?" And these are questions which, as we shall find hereafter, had need to be asked, and were asked with effect and advantage when the Aristotelian province of thought had endeavoured to bring all other provinces within it. But for any further purpose than for destroying this pretension they are impertinent. When I study an actual man or an actual horse, the substance is doubtless the *or* unknown quantity which I am inquiring after to assume that I know it, is to stop all investigation. But I understand the *name* substance as well as I understand the *name* man or horse. And who told you that, because there is a science of *things*, there is not a science of *names*? that there are not laws of dependence and affinity among them? and that conformity or nonconformity to these laws is not exactly what we mean by coherent or incoherent discourse? There is no alter

sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

native between the assertion, that the desire so deeply implanted in us of arrangement and classification is a mere disease, or the belief that it arises from the sense of certain limitations and conditions to which our minds themselves are subject, and is another name for the wish to understand what they are.

The rules of grammar, the terminology of every art and science, the very attempt to be intelligible, presume these. And there is no safety from the efforts of men to invent divisions and schemes of thought, no safety for the great principles and laws, which these dividers and schemers are continually narrowing and stifling, but in the clear and steady perception of certain necessary boundaries not imposed upon us by our fellow-men, but by the nature of our own understandings. Let then the reader carefully consider this work on the *Categories*. Let him ask himself whether it has not the effect of clearing his mind, and that in no ordinary degree, respecting his own modes of speech; whether it does not lead him to feel more than he did before, that his words, winged though they may be, can take no chance flight, but must move along an appointed preordained path; and, therefore, whether there be not a witness in himself that Aristotle has a distinct and reasonable end of his own, which it is very much for our interest to be acquainted with.

The treatise
Περὶ
Ἑρμηνείας.

From the investigation of these general forms under which we reduce all the notions that enter our minds, he proceeds in his treatise *Περὶ Ἑρμηνείας*, to inquire respecting the mode of our affirmations and denials. In this treatise he develops the nature and limitations of propositions, the meaning of contraries and contradictories, the force of affirmations and denials, in impossible, contingent, and necessary matter. This subject has been so fully treated in the article LOGIC in a former volume of this *ENCYCLOPÆDIA*, that we can have no excuse for travelling over the same ground. For the same reason we must say nothing respecting the two books of *Ἀναλυτικά Προτερα*, which develop the syllogistic principle and process. But we cannot sufficiently impress on our readers the remark which has been made already for another purpose in that article, that Aristotle is not in these books the mere inventor of an art, but the masterly expounder of the facts upon which that art rests, and but for which it would have no meaning. He does not teach us how to make propositions, but what propositions are, and necessarily must be, according to the conditions of the human intellect. He does not tell us how to make syllogisms, but how we do syllogize, when we do not violate the laws of our mind as much as we should violate the laws of our body, if we tried to walk upon our heads instead of upon our feet.

The first
Analytics.

The later
Analytics.

But Aristotle perceived that this analysis of our mental operations was not sufficient. He had told us how we *discourse*, but he had not told us how we *know*. Are these forms of Logic themselves knowledge? Is the syllogistic demonstration the same thing with science? Or, is one kind of it science? Or, are the results of it science? Or, are there certain premises assumed in it which also do or may belong to science? What are these? how do we get at them? Such are the important inquiries which occupy Aristotle in his *Ἀναλυτικά Ὑστερα*. We shall endeavour to seize a few of those points in the investigation which will best enable the reader to estimate the character of Aristotle's mind, and to see how he stands related as well to his great master as to the expounder of the inductive philosophy.

The treatise opens thus: Πᾶσα διδασκαλία καὶ πᾶσα μάθησις διανοητικὴ ἐκ προϋπαρχούσης γίνεται γνώσεως. φανερόν δὲ τοῦτο θεωροῦσιν ἐπὶ πασῶν. αἱ γὰρ μαθηματικαὶ τῶν ἐπιστημῶν διὰ τοῦτον τοῦ τρόπου παρά- γίνονται καὶ τῶν ἄλλων ἕκαστη τεχνῶν. ὁμοίως δὲ καὶ περὶ τοὺς λόγους οἱ τε διὰ συλλογισμῶν καὶ οἱ δι' ἐπαγωγῆς. ἀμφότεροι γὰρ διὰ προγινωσκομένων ποιοῦνται τὴν διδασκαλίαν οἱ μὲν λαμβάνοντες ὡς παρὰ ξυνιέντων οἱ δὲ δεικνύντες τὸ καθόλου διὰ τοῦ δήλου εἶναι τὸ καθ' ἕκαστον. ὡς δ' αὐτῶς καὶ οἱ Ῥητορικοὶ συμπίθουσιν. ἡ γὰρ διὰ παραδειγμάτων ὅπερ ἐστὶ ἐπαγωγή ἢ δι' ἐνθυμημάτων ὅπερ ἐστὶ συλλογισμός. There are two very important words in the opening clause of this sentence which we imagine were carefully distinguished in the school from which Aristotle came, διδασκαλία and μάθησις. We feel confident, also, that the last being, by the force of its name, the method of learning and acquisition, would have uniformly taken precedence of the other, which points to the communication of knowledge. That the order is here changed, that διδασκαλία is put foremost as if it included the other within itself, is a very significant circumstance, which is an explanation of much that follows. Plato, it is well known, had a profound reverence for mathematics. He was wont to say, "Let no man undisciplined in geometry enter the halls of philosophy." Now we cannot account for this admiration unless we suppose him to have perceived in the mathematical process something akin to his own method. But this resemblance certainly does not lie in that which we are wont to call the mathematical demonstration, it does not lie in the machinery of axioms, definitions, hypotheses, propositions. This machinery, valuable as it is, has scarcely a Socratic element in it. What remains? Plato, we conceive, would have answered, Exactly that which is the essence of mathematics, exactly the μάθησις. For this demonstration is but the διδασκαλία, a necessary and inseparable accident of the science, but implying the presence of something else and unmeaning without it. The μάθησις is the process whereby in any particular triangle I arrive at this as one of the laws which belong to it as a triangle, that its three angles are equal to two right angles; the διδασκαλία is the formal verbal enunciation of that law and the confirmation of it by certain deductions from previously admitted premises. In this sense mathematics would seem to him not indeed the science but the best preparation for it, because it recognises certain permanent forms and principles existing in visible objects, which we are capable of entering into and discovering. Now Aristotle, as we have often hinted, perceives only the forms and laws of our mind. That, consequently, which was the subordinate and accessory part of mathematics in the judgment of his master, became in his judgment the whole. He looks upon mathematics simply in reference to its demonstrations; the characteristic of mathematics is that it deals with necessary matter. If you ask why necessary, the only answer you can get is, that it starts ultimately from some self-evident propositions. So that, after all, the proposition, a mode of our own mind, becomes the ultimate ground of all things. Or if you will find out a Hercules' pillar beyond these, you have the *Categories*. Pent within these limits, it becomes difficult to grasp the meaning of science. Aristotle feels the difficulty, and with his usual honesty does not evade it. He acknowledges that it may puzzle us to tell whether science is only that which we obtain after a series of satisfactory syllogisms, or whether the premises assumed in those

percep-
tions.

sylogisms must not of themselves be entitled to the same character. And he can only say, that we must deal fairly with facts, and that what we are bound to assume as known, we do actually in some sort know. Ultimate knowledge then, as well as primary knowledge, the most perfect truth which the philosophers can attain, as well as the point from which he starts, is still a proposition. All knowledge seems to be included under the two forms,—knowledge that it is so, knowledge why it is so. Neither of these can of course include the knowledge at which Plato is aiming, knowledge which is correlative with being—a knowledge not about things, or persons, but of them.

But if these forms of our mind be the ground of our knowledge, we cannot at once arrive at them. What are the steps? Here comes in the Aristotelian doctrine about sensible objects. Our perception of these is not strictly to be called knowledge; that word, whether used about premises or conclusions, the data of a syllogism or its results, has still reference to what is universal. Our sensible apprehensions refer only to particulars, to individuals. But from these, which are the most evident to us, we come to the more general by a process of induction. What this induction is, and how entirely it differs from that process which bears the same name in the writings of Bacon, the reader will perceive the more he studies the different writings of Aristotle. He will find, first, that the sensible *phenomenon* is taken for granted as a safe starting point. That phenomena are not principles, Aristotle believed as strongly as we could. But to suspect phenomena, to suppose that they need sifting and probing in order that we may know what the fact is which they denote, this is no part of his system. The sensible impression was to him satisfactory, not indeed to rest in, but as a true beginning; all the difference between those who acquiesce in it and the most consummate philosopher lay in the use which the latter made of his power of generalizing and syllogizing. It is in this way that Aristotle has become the parent of all the modern schools of sensible philosophy, which schools have, nevertheless, drawn their very best and most convincing arguments from the errors into which Aristotle and the Aristotelians were led by the adoption of their own hypothesis. The first book of Locke may be justly said to be an elaborate and satisfactory exposure of the notions into which the Stagirite school is driven, by its determination to recognise no foundation of truth but sense and experience. They were too learned and thoughtful not to perceive that universal forms are in some way or other demanded by the mind; and because they would not acknowledge them as the grounds of our mind, they are forced to seek for them in the mind, and thus to conceive them in the shape of propositions. Hence the fancy of an innate notion that whatever is, is; that the whole is greater than its part, &c.; a fancy which Mr. Locke has confuted amidst such shouts of triumph from his admirers, while he was, in fact, conspiring with Aristotle to disparage the principle which delivers us from such fallacies. But we are anticipating a future page of our sketch.

The *Topics*. These *Αναλυτικά Υστερα* deal, it will be seen, entirely with demonstrative reasoning. The *Topics*, a much longer work, refer wholly to probable reasoning. On this subject Aristotle, it seems to us, is much more at home than on the other. We have intimated our suspicion that he never did possess or could possess the

idea of science. It lay altogether out of his province; when he tried to grapple with it he necessarily brought it within conditions and forms which robbed it of its very essence. But no one ever did so much as he to give a scientific form and semblance to those subjects which are by their nature not scientific. No one ever did so much to give our thoughts precision and clearness respecting all the wavering and fluctuating matters that fall within the domain of opinion and of ordinary conduct. When we look at the *Topics*, we are brought to confess (not without a certain reluctance) that there is no method of persuasion or human discourse so loose and random but that it may be subjected to analysis, and shown to involve certain inevitable limitations. Undoubtedly there is some justification for our discontent with these resolute reductions of all our thoughts and arguments to a system; we feel that the vital power is not there; that what really brings men into consent with either a falsehood or a truth, the energy and conviction of him who utters it, is taken no account of, and that the habit of contemplating arguments without reference either to the truth of that which they are meant to establish, or to the moral influence which they exert, is somewhat hardening and deadening to the mind. But we shall find that the work of a thorough master in this line, like Aristotle, will on the whole produce a good effect. He so entirely understands himself and what he is able to do, that we cannot commit the mistake which inferior writers often draw us into, of fancying that nothing is wanted but what he tells us. His exquisite dissections teach us what more blundering dissections might not; that there is something which cannot be dissected. To understand Aristotle rightly, the *Topics* should be read together with the three books on Rhetoric. We cannot speak of that work now because so much of the moral and political wisdom of Aristotle is presumed in it. Nevertheless it is closely connected with this work on probable arguments. The *Topics* are to it what the six books of Euclid are to a treatise on practical mechanics. Now, though it may seem strange to talk of a geometry expressly for a rhetorician, and though we have already shown in what sense geometry was very alien from the habits of Aristotle's mind, yet we cannot help seeing that just so far as a person who has the faculty of persuasion can be taught that his is not a mere craft, but has maxims and laws to govern it, he will become at any rate less mischievous, and may become a sincere, true-minded man. In another point of view the *Topics* give that roundness and completeness to the logical system of Aristotle which we said that he evidently desired, and had in so remarkable a manner realized.

The last treatise of Aristotle directly upon a logical subject, is that *On Sophistical Proofs*. From this short work we should pass in a complete criticism upon his works to his voluminous writings on physics. In these we have no direct interest. To show, however, how the logical ideas of Aristotle affected his views in this department, we shall take the liberty of extracting a passage from Mr. Whewell's *History of the Inductive Sciences*, vol. i. sec. 2. "The Aristotelian Physical Philosophy."

"The principal treatises of Aristotle are, the eight books of *Physical Lectures*, the four books *Of the Heavens*, the two books *Of Production and Destruction*, for the book *Of the World*, is now universally acknowledged to be spurious, and the *Meteorologics*, though full of physical explanations of natural phenomena, does

Moral and

losophy.

Moral and
Metaphysical
Philosophy.

not exhibit the doctrines and reasonings of the school in so general a form; the same may be said of the *Mechanical Problems*. The treatises on the various subjects of natural history, *On Animals*, *On the Parts of Animals*, *On Plants*, *On Physiognomies*, *On Colours*, *On Sounds*, contain an extraordinary accumulation of facts, and manifest a wonderful power of systematizing; but are not works which expound principles, and therefore do not require to be here considered.

Extract
from
Whewell
on the
inductive
sciences.

"The *Physical Lectures* are the works concerning which the well known anecdote is related by Simplicius, a Greek commentator of the VIth Century, as well as by Plutarch. It is said that Alexander the Great wrote to his former tutor to this effect: 'You have not done well in publishing these *Lectures*, for how shall we, your pupils, excel other men if you make that public to all which we learned from you?' To this Aristotle is said to have replied: 'My *Lectures* are published and not published; they will be intelligible to those who heard them and to none beside.' This may very easily be a story inscribed and circulated among those who found the works beyond their comprehension; and it cannot be denied that to make out the meaning and reasoning of every part would be a task very laborious and difficult, if not impossible. But we may follow the import of a large portion of the work with sufficient clearness to apprehend the character and principles of the reasoning, and this is what I shall endeavour to do.

"The author's introductory statement of his view of the nature of philosophy falls in very closely with what has been said, that he takes his facts and his generalizations as they are implied in the structure of language. 'We must in all cases proceed,' he says, 'from what is known to what is unknown.' This will not be denied; but we can hardly follow him in his inference. He adds, 'We must proceed, therefore, from universal to particular. And something of this,' he pursues, 'may be seen in language; for names signify things in a general and indefinite manner, as *circles*, and by defining we unfold them into particulars.' He illustrates this by saying, 'thus children at first call all men *father*, and all women *mother*, but afterwards distinguish.'

"In accordance with this view he endeavours to settle several of the great questions concerning the universe which had been started among subtle and speculative men, by unfolding the meaning of the words and phrases which are applied to the most general notions of things and relations. We have already noticed this method. A few examples will illustrate it further: whether there was or was not a *void* or place without matter, had already been debated among rival sets of philosophers. The antagonist arguments were briefly these: there must be a void because a body cannot move into a space except it is empty, and therefore without a void there could be no motion; and, on the other hand, there is no void, for the intervals between bodies are filled with air, and air is something. These opinions had even been supported by reference to experiment. On the one hand, Anaxagoras and his school had shown, that air when confined resisted compression, by squeezing a blown bladder, and pressing down an inverted vessel in the water; on the other hand, it was alleged that a vessel full of fine ashes held as much water as if the ashes were not there, which could only be explained by supposing void spaces between the ashes. Aristotle decides that there is no void on such arguments as this:—In a void there could be no difference of up and down; for as in nothing there

are no differences, so there are none in a privation or negation; but a void is merely a privation or negation of matter; therefore, in a void, bodies could not move up and down, which it is in their nature to do. It is easily seen that such a mode of reasoning elevates the familiar forms of language and the intellectual connections of terms to a supremacy over facts; making truth depend upon whether terms are or are not primitive, and whether we say that bodies fall naturally. In such a philosophy every new result of observation would be compelled to conform to the usual combinations of phrases as they had been associated by the modes of apprehension previously familiar.

"It is not intended here to intimate that the common modes of apprehension, which are the basis of common language, are limited and casual. They imply, on the contrary, universal and necessary conditions of our perceptions and conceptions; thus all things are necessarily apprehended as existing in time and space, and as connected by relations of cause and effect; and, so far as the Aristotelian philosophy reasons from these assumptions, it has a real foundation, though even in this case the conclusions are often insecure. We have one example of this reasoning in the eighth book, where he says that there never was a time in which change and motion did not exist; 'for if all things were at rest, the first motion must have been produced by some change in some of these things; that is, there must have been a change before the first change;' and again, 'How can *before* and *after* apply where time is not? or how can time be when motion is not?' 'If,' he adds, 'time is a mensuration of motion, and if time be eternal, motion must be eternal.' But we have sometimes principles introduced of a more arbitrary character, and, besides the general relations of thought, the inventions of previous speculators are taken for granted; such, for instance, as the then commonly received opinions concerning the frame of the world. From the assertion that motion is eternal, proved in the manner just stated, Aristotle proceeds by a curious train of reasoning to identify this eternal motion with the diurnal motion of the heavens. 'There must,' he says, 'be something which is the first moved;' this follows from the relation of causes and effects. Again, 'Motion must go on constantly, and therefore must be either continuous or successive. Now, what is continuous is more properly said to take place *constantly*, than what is successive. Also the continuous is better; but we always suppose that which is better to take place in nature, if it be possible.' We see here the vague judgment of *better* and *worse* introduced, as that of *natural* and *unnatural* was before into physical reasonings.

"I proceed with Aristotle's argument, 'We have now, therefore, to show that there may be an infinite, single, continuous motion, and that this is circular.' This is, in fact, proved, as may readily be conceived, from the consideration that a body may go on habitually revolving regularly in a circle. And thus we have a demonstration, on the principles of this philosophy, that there is and must be a first mover, revolving eternally with a uniform circular motion.

"Though this kind of philosophy may appear too trifling to deserve being dwelt upon, it is important for our purpose so far to exemplify it that we may afterwards advance, conscious that we have done it no injustice.

"I will now pass from the doctrines relating to the

Moral and

Philosophy.

Moral and
Metaphy-
sical Phi-
losophy.

motions of the heavens to those which concern the material elements of the universe. And here it may be remarked, that the tendency (of which we are here tracing the developement) to extract speculative opinions from the relations of words must be very natural to man; for the very widely accepted doctrine of the four elements, which appears to be founded upon the opposition of the adjectives *hot* and *cold*, *wet* and *dry*, is much older than Aristotle, and was probably one of the earliest of philosophical dogmas. The great master of this philosophy, however, puts the opinion in a more systematic manner than his predecessors.

"We seek," he says, "the principles of sensible things, that is, of tangible bodies. We must take, therefore, not all the contrarieties of quality, but those only which have reference to the touch. Thus black and white, sweet and bitter, do not differ as tangible qualities, and therefore must be rejected from our consideration."

"Now the contrarieties of quality which refer to the touch are these, hot, cold; dry, wet; heavy, light; hard, soft; unctuous, meagre; rough, smooth; dense, rare." He then proceeds to reject all but the four first of these, for various reasons; heavy and light because they are not active and passive qualities; the others because they are combinations of the four first, which, therefore, he infers to be the four elementary qualities.

"Now in four things there are six combinations of two; but the combinations of two opposites, as hot and cold, must be rejected; we have, therefore, four elementary combinations which agree with the four apparently elementary bodies, air is hot, wet, (for steam is air,) water is cold and wet, and earth is cold and dry."

"It may be remarked that this disposition to assume that some common elementary quality must exist in the cases in which we habitually apply a common adjective, as it begun before the reign of the Aristotelian philosophy, so also survived its influence. Not to mention other uses, it would be difficult to free Bacon's *Inquisitio in Naturam calidi*, 'Examination of the Nature of Heat,' from the charge of confounding together very different classes of phenomena under the cover of the word *hot*.

"The rectification of these opinions concerning the elementary composition of bodies belongs to an advanced period in the history of physical knowledge, even after the revival of its progress."

"The Aristotelian doctrines concerning motion are still founded upon the same mode of reasoning from adjectives; but in this case the result follows, not only from the opposition of the words, but also from the distinction of their being *absolutely* and *relatively* true. 'Former writers,' says Aristotle, 'have considered heavy and light *relatively* only, taking cases where both things have weight, but one is lighter than the other; and they imagine that in this way they defined what was *absolutely* (απλως) heavy and light.' We now know that things which rise by their lightness do so only because they are pressed upwards by heavier surrounding bodies; and this assumption of absolute levity, which is evidently gratuitous, or rather merely nominal, entirely vitiated the whole of the succeeding reasoning. The inference was that fire must be absolutely light, since it tends to take its place above the three other elements; earth absolutely heavy, since it tends to take its place below fire, air, and water. The philosopher argued also with great acuteness that air, which tends

to take its place below fire and above water, must do so *by its nature*, and not in virtue of any combination of heavy and light elements. For if air was composed of two parts, which give fire its levity, joined into other parts which produce gravity, we might assume a quantity of air so large that it should be lighter than a similar quantity of fire, having more of the light parts. It thus follows that each of the four elements tends to take its own place, fire being the highest, air the next, water the next, and earth the lowest. The whole of this train of errors arises from fallacies which have a verbal origin; from considering light as opposite to heavy, and from considering levity as a quality of a body, instead of as the effect of surrounding bodies."

These remarks of Mr. Whewell's show how necessarily the method of Aristotle obstructed the true observation and interpretation of nature. To us they are important chiefly from the connection which has always been felt to exist between the physical treatises and those which by Aristotle himself or some disciple are classed under the name of Metaphysical. These latter writings have been the subject of much dispute. Some have supposed that they owe their name to an accidental juxtaposition with the books on nature, among which it was evident that they could not conveniently be classed; some to a feeling in the mind of Aristotle, that he was ascending into a higher region, above and beyond that in which he had been dwelling previously.

One of his early commentators appears to adopt both explanations of the title. "We," he says, "make our beginning from those things which in nature are the last, seeing that these are the better known to us. For this reason, then, he discourses to us first concerning physical matters, for these are last in nature, but to us first. But this present subject is first in nature, but to us last, for the imperishable things are older than the perishable, and the ungenerated than the generated. Aristotle then discourses to us first concerning those things that are moved without an order, (in his book on *Meteors*;) then again concerning those things which are moved according to an order or system, (in the work on the *Heavens*, concerning the stars and the spheres;) and finally in this treatise he discourses to us concerning those things which are in all cases unmovable. Now this is theology, for such a study befits the gods. For this reason the work is inscribed *After-the-Physics*. (Μετα τα φυσικά,) seeing that he first discoursed to us concerning the physical things, then consecutively concerning this; it is proper, therefore, to read it after the physical treatises; this the title shows." Another of the Scholiasts is more decisive: "This work is entitled *Μετα τα φυσικά*, not in reference to the character of the book, but to the order in reading it, for he treats concerning physical *principles*." These hints, if considered in connection with the books themselves, will, we conceive, explain the origin of the two theories, and in a great degree reconcile them. Without pretending to ascertain the proper succession of treatises which are comprised in this division of the works, there can be no doubt, we imagine, that the review of previous Greek philosophers is the intended introduction to the rest. This review is prefaced by the remark, that there is a kind of knowledge to which the word wisdom (σοφία) is especially applicable; it is conversant with principles, (αρχαί.) These principles may be looked for in four ways. Either in the subject-matter, (η ὕλη και το ὑποκείμενον,) or in that which produces motion, (ὅθεν ἡ αρχη της κινήσεως,)

or in the substance, (*ἡ οὐσία καὶ τὸ τι ἦν εἶναι*), or in its purpose, (*τὸ οὐ ἐνεκα*.) Aristotle believes that one or other of these courses of inquiry was followed by each school of Greek thinkers, and was considered by that school as the only and all-sufficient method. Thus the Ionic philosophers studied the matter of things in hopes of discovering a primary element to which all other things might be referred. Those of this class who selected fire as their element were naturally led by the effects which they observed resulting from that power to speculate upon the meaning and mystery of Motion. Hence a new kind of inquiry was started, which proceeded, however, much in the spirit of those respecting Elements till Anaxagoras discovered the necessity of an Intelligence to set physical agents in movement. As, however, he had only recourse to this ultimate principle when other instruments failed him, the Atomic theory, which furnished a more plausible explanation of the facts of nature than his Homæomeriæ, easily supplanted them. Between this theory and that which affirmed Numbers to be the first principles of things, Aristotle appears to detect a connection, one not well supported by chronology. That doctrine of numbers he considers the first form of the inquiry after the Essence or Substance of things. The archetypal Ideas of the Platonists, who regarded numbers as a kind of intervening powers between sensible things and pure essences, is the second and higher form of it. The inquiry respecting the object or purpose of things had not, he imagines, been pursued distinctly by any class of his predecessors, but it had entered somewhat confusedly into the speculations of them all.

How far this able and interesting sketch of previous systems is satisfactory we need not now stop to inquire. We have given our reasons, which might, we think, be confirmed by many unconscious testimonies from Aristotle himself, for regarding Socrates as the key-stone of Greek speculations. If Aristotle be right, he was only an accident or interloper among them—of right, therefore, only mentioned in a parenthesis as chiefly devoting himself to ethical questions, Plato's intellectual descent being traced not through him to the Italian and Heraclitan schools. We might derive much evidence in favour of our view from the remarks respecting the mixture of the fourth class of inquiries which had reference to the intention or utility of things with the three which were suggested by physical observation. We might show, from the tone of the whole treatise, that Aristotle did not sympathize enough with his predecessors to understand the complicated thoughts which were at work in them, and was therefore naturally tempted to find classifications where no classification existed. But we do not refer to this book as a help in understanding Aristotle's predecessors, but Aristotle himself. It removes, we think, almost entirely the difficulty which has been raised respecting the use of the word Metaphysics in application to this and to the twelve books which follow it. It is evident that he is here tracing the method by which, as he supposes, men were led to discover in Physics something beyond Physics, which is their necessary ground. To say that all these inquirers discovered something which was distinct from physics was far from his meaning. It is one of his great objects to show that the first seekers after a principle really went no further than the mere outside facts which they proposed to investigate; still they, as much as the others, were in search of an *αρχή*. Their

inquiries, as much as those of their successors, (some of whom, as the Atomists, were as purely physical as they had been,) must be classed among the *τα μετὰ τὰ φυσικά*; for they groped at these if they did not find them. The simplest explanation, then, which has been given of the expression is in one way the truest. But that explanation by no means excludes, nay it involves, the belief that Aristotle is finding out the nature, and defining the objects of a science not merely coming next in order to physics, but, in kind, transcending them; and, we conceive, there is no difficulty in understanding why this word may have now first been consecrated to such a purpose, though the inquiries which we have called metaphysical had been proceeding for so long a time in Greece. Not only has it happened in a thousand cases that the name for a study has not been invented, or at least, not authoritatively stamped and circulated till it has performed its greatest achievements, and the ardour for it has declined—not only is Aristotle peculiarly the definer of boundaries, the systematizer of thoughts, previously living and at work—but also it might be inferred as much from the common view of Greek philosophical history which we have taken, as from his more ingenious view, that it would have been impossible, before his time, to have comprehended, under one such word as this, the subjects which are here expressed by it. Aristotle is confessedly feeling his way to a distinction which, according to our notion, they could not recognise, which, in his notion, at all events, they had not recognised. How questions regarding nature are connected with man, or what common ground there is for both was, we have suggested, the great puzzle of those philosophers, who busied themselves, as Aristotle says, with the *ὑλη*. That they should have formally separated them, no one would expect. An entire confusion of speculation with practice was the characteristic of the Sophists. They endeavoured to turn practice into speculation. Socrates endeavoured to make all speculation practical. Plato showed how the practical ground necessarily involved an absolute truth which the speculative eye only could behold. It remained then for our philosopher to make this partition, to assign one region to the philosopher as a philosopher, another to men as men, and as a necessary consequence, to make the region of philosophy a region in some way connected with nature, though passing beyond it.

We are very anxious that this point should be understood, because the history of subsequent philosophical inquiry in a great degree turns upon it. The metaphysics of Aristotle are troublesome reading, partly from the frequent repetitions which occur in them, partly from the difficulty of discovering a sequence in the books. Nevertheless they should be read by any student who wishes to investigate the questions which have occupied men in later times. We shall illustrate our previous remarks by tracing a very rude outline of the subjects which are discussed in them, and recording some of the solutions Aristotle has given of the difficulties which he starts.

A kind of appendix which follows the first book contains a proof that causes are not infinite, that there is consequently a possibility of carrying on that inquiry in which past philosophers had engaged. The same short book contains some important remarks upon the manner in which the search was to be conducted, upon the contributions to truth which each school may have made, upon the advantages which a philosopher may derive

Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

from attending even to popular notions, upon the dislike which some have to exact mathematical reasoning, and the determination of others to have nothing else, and upon the proper limitation of mathematical accuracy to things without matter. We have here also the clear announcement of a principle which the student of Aristotle would have need to keep constantly in recollection, θεωρητικῆς μὲν τέλος ἀλήθεια, πρακτικῆς δ' ἔργον. He adds an explanation, which still further illustrates his meaning, and makes the difference between him and his master more conspicuous, that the practical man has nothing to do with the eternal or the absolute, but only with the relative. This book ends with a promise of an inquiry into the meaning of the word nature, which is not however fulfilled in that which is commonly placed next to it.

This second book is a collection of doubts or questions to be hereafter resolved. The first doubt is, whether it is the business of one science, or of more, to inquire into all kinds of causes or principles. This question involves the very subject of the whole treatise. So many different subjects seem to be included in that province to which the general name σοφία has been given—matters purely belonging to the senses, the causes of motion, the nature of being, the reason and purpose of things—how is it possible to suppose a single science dealing with principles apparently not admitting either of analogy or contrast? Secondly, are we to look upon the most comprehensive genera to which individual things can be referred, or upon the atoms of which they consist as their principles? The third question is connected with this, is there any thing besides individual things? If not, how can they be known, for are not individual things infinite, and is not knowledge of that which is one and universal? Fourthly, are the principles of things perishable, and of things imperishable, the same? Fifthly, (which is the great question of all,) are Being and Unity the essences of things that are and not distinguishable from them, or are we to seek for the το ον and the το ἐν as if they had each a distinct nature? Sixthly, are numbers, bodies, planes, and points, substances or not? Such are the general controversies of which we are to hope for some settlement in the books that follow.

The third book may be considered an answer to the first question. There is a Science which contemplates Existence as Existence, and whatever appertains to it in reference to it, not like other sciences, merely the attributes of certain particular existences. There are, he says, certain things peculiar to Being as Being, and these are things concerning which it is the philosopher's function to investigate the truth. The dialectician and the sophist resemble indeed the philosopher; being is the common subject-matter to all three. They discourse concerning the subjects which are in a peculiar sense his property. The dialectical δύναμις differs from the philosophical in its nature; the sophistical in the intention of him who uses it (τον βιον τῇ προαίρεσει). ἐστι δὲ ἡ διαλεκτικὴ πειραστικὴ περὶ ὧν ἡ φιλοσοφία γνωριστικὴ ἢ δὲ σοφιστικὴ φαινόμενη, οὐσα δ' οὐν. This is an important passage as illustrating the difference between the Platonic and the Aristotelian dialectics. According to Plato dialectics was the human science, the science of the philosopher as such. Σοφία in its essence belongs to God. Aristotle, we see, discovers a difference between dialectics and the highest philosophy, and inevitably; for, as his dialectic treats only of the forms of

human thought, as it deals with knowledge merely in the sense of the powers and means of knowing possessed by us, there must be another science concerning the objects of knowledge as such. But then, in this science also, the objects cease to be objects, they become *subjects* for man's contemplation, they become Metaphysics or Ontology. The hint respecting the *Sophist* contained in this sentence should also be compared with the elaborate exhibition of his character and functions in the dialogue between the Eleatic stranger and Theætetus. It connects itself with the inquiry, whether mathematical axioms are subjects of inquiry for the Ontologist or highest philosopher. The answer is in the affirmative. Those axioms were assumed by the mathematician. The student of physics sometimes meddles with them, but rashly and presumptuously; they are first principles, or *αρχαί*, and as such are cognizable only by the person whose office we are defining. Now as it was the especial delight of the sophist to deny axioms, to say that the same thing could be and not be, this becomes the natural place for settling his pretensions. Consistently with their characteristic difference, Aristotle represents him, not in Plato's manner, as one who invents counterfeit images of that which is, but as one who attributes accidents to accidents instead of to substances. We can scarcely conceive two portraits of the same person so correct and felicitous, and yet expressing so thoroughly the manner and principle of their respective artists.

The fourth book is a book of definitions. We can only convey a notion of its importance by giving a list of the words defined. They are Principle, (*αρχή*), Cause, Element, Nature, Necessity, Unity, Being, Substance, Sameness, Opposition, First and Last, Power, Quantity, Quality, Relation, Perfection, Limitation, *Τὸ καθ' ὃ* (*secundum quid*); [the meaning is easily understood from Touchstone's words in *As You Like It*, "In respect that it is of the country it is a good life, but in respect that it is not of the court it is a vile life, &c."] Disposition, Habit, Passion, Privation, Inclusion, Derivation, Part, Whole, *κολόβον*, (the mutilated,) Kind, Falsehood, Accident. The explanations of some of these words will, it is obvious, have been repeated from the *Categories* and the *Analytics*. Some of them will be better understood from the arguments in the subsequent books than they could be from any formal definitions; still they are worthy to be read and reflected on. The one on "Nature" is perhaps the most important, but to his notions of this word the entire treatise is the only satisfactory clue.

The fifth book explains Aristotle's view of the difference between physical and ontological science. They agree in this, that they are theoretic not practical or poetic. They differ in this, that the physical deals with that which has a capacity for change or movement, and with that which is embedded in matter. The primary philosophy deals with the unchangeable and with that which is separate from matter. Mathematical science lies between them, resembling ontological science in the first characteristic, physical in the second. If there be such a science as Theology, it must be a part, and the highest part, of the primary Philosophy. The *το θεῖον* (the divine nature) must be pre-eminently *των ἀκινήτων καὶ χωριστῶν*. The condition of those things whereof physical science treats, is that they are susceptible of accidents; not that there can be a science of accidents; as such they exclude science altogether.

losophy.

But there may be, and there are, principles and causes of those things which admit of accidents, which are not themselves in any sense accidents, but are necessary. Pursuing these, physical science still retains its formal distinction from that higher science which deals with existences and essences as such. There is another sense in which the phrase *τοον* had been used, especially by the Platonists, which it is necessary to distinguish from our notion of it. It had been confounded with truth; not being with falsehood. Now truth, according to Aristotle, is not in the things but in the mind. Affirmation combines, negation separates, falsehood separates that which should be combined, combines that which should be separate. But the existences with which we are dealing are simple or uncompounded. Here again we have one of the capital and vital points of difference between the two philosophies.

The sixth book contains some of the most important distinctions and differences in the whole treatise. It begins with repeating a remark previously made, that Ontology has a twofold object. It deals first with that of which other things are predicated; secondly, with that which is predicated of it. Now substance is that of which other things are predicated. What then is to be included among substances? Are walking, sitting, being in health, substances? No, all these imply a subject, to which they must be considered as referring. In this way we get rid of the notion of an essential good, as well as an essential warmth or whiteness, &c. All these alike are considered as qualities of some subject, and what that subject is must be sought in each individual which offers itself to our observation.

But does not substance when thus considered necessarily connect itself with body? Here is one of our great puzzles. Some would have the *boundaries* of body to be substances; some would have substances which are in no sense cognizable by the senses; some would make the One the primary substance, and suppose different sets of substances, such as numbers, magnitudes, souls, to be generated from this. Aristotle's opinion is this. To every subject belongs, first, *ύλη*, which we must translate matter; secondly, *μορφη*, or form. The matter of a thing is not merely an accident of it, it is its necessary condition. But this matter is not its essence; something else is implied in it, something which it presents or makes manifest. Applying this principle to the questions which occupied the third class of philosophers, mentioned in the introductory book,—the Platonists namely, and the Pythagoreans,—it appears that this form is the true *είδος* of which they dreamed. It is the essential thing in each thing; it is not substance such as we behold it, but that in virtue of which substance is possible, without which it is inconceivable. But it does not exist apart from each particular substance; it is that which enters into the definition of every subject, and without which the definition would be no definition; obviously, therefore, it must be viewed in that subject, and cannot be contemplated as a distinct, peculiar essence. Tested by this rule it is obvious also that all notions of an ideal form of hollowness or of pugnosedness (we use Aristotle's favourite illustration) must be out of the question; these cannot be, primarily at least, subjects for a definition; they presuppose something whereof they are properties, and in that, and that only, can you look for an *είδος*. All notion again of Being as distinct from the particular person who, or the thing which is, falls to the ground.

Socrates and the being of Socrates are identical; the *αυτοεκαστον*, of which he had talked, is nothing else but this *είδος*, or form inherent in the thing itself.

The mode in which this same principle is applied to another class of inquiries, those which relate to the genesis or first origin of things, requires a more minute examination.

In considering any production, we find, first, something whence it has been generated; secondly, something by which it has been generated; thirdly, the result or the thing itself. There are three modes of production—natural, artificial, automatic. In natural productions we discern at once a matter; nay, in the largest sense, Nature itself may be defined that out of which things are produced. Every thing that becomes has a nature, which is only another way of saying that it has a *ύλη*; and that in each thing which might not have been is this *ύλη*. Now the result formed out of this matter or nature is any given substance—a vegetable, a beast, a man. But what is the producing, generating cause in each case? Clearly something akin in kind to the result. A man generates a man. Then we suppose in the resulting thing a productive force distinct from the matter upon which it works. And this is our *είδος*. And it is the combination of this *είδος* with the *ύλη* which both produces a substance and constitutes it. Look now at artificial productions. Here the *είδος* is still the producing power. It is in the soul. The art of the physician, the plan of the architect, is that *είδος* which produces actual health or an actual house. Here, however, a distinction arises. In these artificial productions is supposed a *νοησις* and a *ποιησις*. The *νοησις* is the perception and internal entertainment of the form; the *ποιησις* the creation out of the given matter. But we mentioned a third mode of production not strictly natural or artificial, but by the action of the thing itself. For instance, a cure may take place by the application of warmth; a body may become warm by rubbing; this warmth then in the body is either itself a portion of health or something is consequent upon it like itself, which is a portion of health. Evidently this implies the previous presence either of nature or of an artificer. Evidently also there is a necessity that this kind of generative influence should combine with another. There must be a productive power; there must be something out of which it is produced. In every case there will be an *ύλη* and an *είδος*. Upon this principle, that which is generated is the whole substance, consisting of matter and form. But the form, properly speaking, is not generated. It is reproduced in each particular subject in combination with a certain matter, and it becomes a new and peculiar form in virtue of that combination. There is necessary then to every production a certain form and a certain matter; and all the qualities appertaining to this substance which is produced, *must* inhere (not actually, but potentially) in the substance producing, and may belong to the form when they are produced.

It remains to consider how this doctrine bears upon the inquiries of those philosophers who busied themselves with the search after a primary element; (those who sought for the *το ού ενεκα* are reserved for another discussion.) But before we can enter upon this subject several of the doubts in our second book must be resolved. First, as to the meaning of the words Part and Whole. The first and most obvious signification of part has relation to quantity; but this has

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

nothing to do with our subject. What we want to know is the connection of the idea of part with substance. Assuming the division of substance into *ύλη* and *εἶδος*, we should say that in a brass statue the brass formed part of the statue, as the complex of form and matter, but not of the statue considered as a Form. Now as Form is the proper subject of a definition; as it can be described in itself, and as that which is material cannot be so described, it comes to pass that in certain cases we necessarily speak of the parts as constituting the whole, and in other cases not. We define a circle without reference to its parts. We define a syllable by the letters or elements which compose it; for the parts of the circle are material parts, the parts of the syllable are formal, logical parts. Of course, if you look upon a syllable as composed of certain letters in wax, or even of sounds in the air, its divisions become material and do not fall within the scope of a logical definition. Again, in a material division you assume the whole as preceding the part. On the contrary, logically and formally, the part precedes the whole. For instance, if you define the life of an animal you will describe it by some of its functions. None of its other functions can be performed without sensation. This particular faculty of sensation, therefore, will precede and be assumed in the existence of the whole animal. This principle holds equally in reference to æsthetic matter, (that which the senses take account of,) as in noetic, (the figures of mathematics.) Generally, therefore, it may be affirmed that the question as to the priority of part and whole depends entirely upon the distinction between matter and form being admitted, and that it is not possible to settle if that distinction be disregarded. At the same time Aristotle admits the difficulty of defining simply with reference to form, and not to the complex substance, which consists of it and of matter together. He acknowledged that the attempt to divide matter from substance and look upon things sensible as not sensible, has led to all the Pythagorean and Platonical inventions, which he regards with so much dislike.

Another question, in which these philosophers are also involved, follows immediately upon this. How are substances connected with *kinds*? If there be certain types after which all sensible things are formed, these types would seem to be universals, and those things with which the senses converse particulars. All possible differences and properties which can be discovered in the most marked individual of any kind must then upon this showing be included in those primitive, universal forms; but, according to logic, precisely the opposite is the case. The genus is divested of the difference which goes to the composition of the species, and of the properties which go to the composition of the individual. Your genera can never be types of the individual. By their very nature they are deficient in all that characterises him. The *εἶδος* then which forms the essential in each thing which makes it be that which it is, must be looked upon as individualized by the *ύλη* with which it is connected, as being apart from the modifications which it thus undergoes only a logical existence, the highest genus to which it is ultimately referred being pre-eminently that which can be only contemplated by and in the mind. Such we take to be the meaning of Aristotle, and from it the doctrine seems to follow very closely with which he winds up this book, and which applies the meaning of it to those who had dealt mainly with the *ύλη*. Any fact or thing being given, I have no

further occasion to trouble myself about the *ὅτι*. This the sense, or something corresponding to sense, supplies. I am not to ask what is the musical man when I see a musical man. He is that which I behold and nothing else. My business is with the *διότι*, the cause. Why is he this or that? And the answer is in the *εἶδος*, the form or constitution. This is the ultimate reason of that which each thing is. Consequently I do not get nearer the cause or reason of things by reducing them into their natural elements. The analysis may be physically proper or useful; but it does not lead me to that of which I am in search. Every thing which is, and which I can either behold with my senses or my mind, is not the A or the B whereof it is composed, but is something else; the synthesis of the A and the B involves the presence of a form or existence, which cannot be found in either of them separately. So that find out as many primary elements as you will, you do not thereby find an *αρχή*.

Our main business then is to discover the meaning of this *εἶδος*, and the relation which exists between it and the *ύλη*. The seventh book takes up this subject, and carries forward a hint which was given in the last—one which is, perhaps, the most pregnant of all the hints in Aristotle's writings, and that which has most effect upon his whole philosophy. The *εἶδος* or *μορφή* is an energy, the *ύλη* is a *δύναμις* or potentiality, implying and requiring the action or co-operation of the energy to produce a result. *Οὐσία*, as we said before, is the synthesis of these; omitting the *ἐνεργεία* you come merely to certain material elements and combinations which do not in any way give you the actual things you are examining. The difficulty is respecting those things which appear to have no *ἐνεργεία* in themselves, as a house. Must the substances of these be considered as something distinct from them and external to them? The answer is this:—Do you mean to ask whether the material house, that is to say the stones and cement, is a substance? Certainly not; you have excluded the very notion of substance by the mode of your question. But do you mean to ask whether that house is actually something? You assume it by your very question. You cannot define any thing without treating it as a substance, satisfy yourself as you will about the reason it is so; there is something then not distinct from the house, but implied in it, which is a form or *εἶδος*. The test that there is, is your own attempt to define it.

Proceeding upon this principle of an energy and a *δύναμις* in each substance, he shows how needful it is in any inquiry after causes to keep the three questions in sight. By cause do you mean potentiality, *δύναμις*? By cause do you mean moving power? By cause do you mean the form? (the two last *may* always be the same; still the inquiry after the constitution of each thing is distinct from the inquiry after its productive force.) Do you mean, lastly, the *οὐ ἐνεκα*? (This also may be the same question with the last, though differently stated; that is to say, the constitution of each thing may determine the purpose or object of it.)

But this use of the word potentiality (*δύναμις*) suggests another doubt. Has not every subject a potentiality for contraries? Must not we say that every healthy body is potentially sick? that water is potentially both wine and vinegar? The answer is that this absence or deprivation of qualities is an accident of these qualities, and not itself a quality. For a dead body to become alive, it must pass into a certain *ύλη*, which has therefore

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

the potentiality of life; for vinegar to become wine it must pass into water; nothing similar happens in the opposite case. Finally, he applies this principle to the solution of that difficulty respecting unity at which he had so often hinted, and on which he had expressed his opinion with sufficient plainness already. If the definition of a man be that he is a biped animal, how comes it that each of these "animal" "biped" do not constitute a separate entity? What, in short, is the ground of our conception of each thing and person as one? Aristotle intimates that this question is hopeless and unanswerable if put in this form, for then by each variety of your definition you create a new puzzle. He would rather then assume the unity of each thing as a fact or datum of the understanding, and account for its being reduced into different constituent elements in a definition. And this is accounted for by the necessary co-presence of matter and form in each thing, and from the matter being merely a potentiality, and the form an energy. In this way the dream of a unity distinct from the individual thing is got rid of, as the dream of a substance distinct from each particular thing had been got rid of before.

The eighth book is still occupied with the subject of potentialities and energies. Aristotle inquires into the different senses of the word *δυναμις*; what we mean when we say that a thing can or cannot be. There is a use of this language in geometry, which is metaphorical, and not to our present purpose. We say that a thing can or cannot be, meaning that it is or it is not. But all *δυναμεις*, in their proper sense, have reference to some primary *δυναμις*, which is the cause or beginning of a change in some other thing as another thing. Warmth, for instance, is a *δυναμις*. It is so equally in that which warms, as in that which is warmed. The *δυναμις* in the thing warmed hath reference or relation to the corresponding primary *δυναμις* in the thing warming, and this necessary implication of that which answers to itself in something besides itself, is its characteristic nature. To every capacity there will of course correspond a certain incapacity, which may be understood either as the absence of a faculty of communication, the absence of a faculty of reception, or, again, merely as a negative want, or as a positive state involving that want.

Δυναμεις are divided into rational and irrational; the rational those which subsist in the reasonable soul, the irrational those that are merely physical. All art and knowledge are of the first class. Now, if we look for a radical distinction between them, we may find it in this way. Warmth, an irrational *δυναμις*, has the power only of producing warmth; the art of the physician has the power of producing either health or sickness. Generally, therefore, the one kind of power can produce contrary changes, the other only a certain change; and these contrary changes are wrought by the rational powers with and upon the irrational powers.

This description of *δυναμεις* might seem in some points to trench upon that notion of energies which Aristotle had given us in his last book. He proceeds therefore to distinguish them. The Megarian sect, in conformity with their general rule of reducing every idea into that of being, and of excluding all distinct notion of production and becoming, had identified Power or Capacity with energy. Where there is no building, said they, there is no builder. Apply this, says Aristotle, to arts, and the man who has studied the longest ceases

to have the art as soon as he ceases to exercise it. Apply it to things without reason or life, and there is nothing sweet, or warm, or cold except at the moment when it is tasted or felt; an argument not, perhaps, very destructive of the proposition in our minds, but which was very effective as against the Megarians, who had the greatest horror of the Protagorean doctrine. It is then possible for a thing to have the capacity of being and not to be, and to have the capacity of not being and to be; that of which it is the capacity takes place where something is superadded to it, which is Energy. Energy is analogous to motion. You cannot predicate either motion or energy of things which are not; the moment energy or motion is added to them they are; but many things which are not have a possible or potential existence.* At the same time energy is not to be confounded with motion. The difference does not lie where we might suspect, in that motion belongs to that which is irrational, energy to the rational, for learning is referred to the head of motion, sight to the head of energy. The difference is in this, that every motion is incomplete, tending towards an end, but not including the end in itself, that energy has an end in itself, and that it does not involve a pause or a termination. Learning, building, walking, all imply a termination. Seeing, thinking, being happy, imply no termination; these are energies.

Upon this showing, energy, in the order of reason and of substance, precedes *δυναμις*; in the order of time not always. It precedes in the order of reason because the first of all capacities or possibilities is the capacity or possibility of energizing. A man who has the faculty of building, is one who has in him the capacity of using his energy in the art of building. In time it is otherwise. The primary energizing power of course precedes, even in this sense, that which receives the impression of it, Form being older than Matter. But if you take the case of any particular person or thing, we say that its capacity of being that person or thing precedes its being such actually or energetically. But then, though this is the case in each particular thing, there is always a foregone energy presumed in some other thing to which it owes its existence. And thus the principle is asserted which we shall find afterwards turned to practical account in the Ethics, that the exercise of any particular energy precedes the habitual use of the faculty appertaining to that energy; that it is by playing on the harp we become harp players. Several important ethical doctrines are in fact developed in the course of this inquiry, but of these we shall take distinct notice hereafter. One pregnant notion more directly bearing upon our present subject occurs in the course of it. *Δυναμις* had been defined that which is the cause of change in some other thing as another thing. But this notion wants a resting place, unless you believe that there is some primary *δυναμις* presupposed in all others, which is the beginning of motion. This is *φύσις*, and thus

* "Ὁὐκ ἔστι δὲ", adds Aristotle, "ὅτι οὐκ ἐντελεχία ἐστίν." Met. 8. iii. 36. This passage, perhaps, determines as clearly as any we could produce the meaning of the word *ἐντελεχία*, which is so important in some branches of the Aristotelian philosophy. It is the opposite to *potentiality*, yet would be ill translated by that which we often oppose to potentiality, *actuality*. *Εἶδος* expresses the substance of each thing viewed in repose,—its form or constitution; *ἐνέργεια* its substance, considered as active and generative; *ἐντελεχία* seems to be the synthesis or harmony of these two ideas. The *effectio* of Cicero therefore represents the most important side of it, but not the whole.

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphysical
Philosophy.

we have arrived at the most complete notion of it which we can expect. And this first and primary cause of all change, Energy still precedes and surpasses. Aristotle proceeds to show wherein energy is better and more glorious than *δύναμις*; as, for instance, because *δύναμις* is the same of contraries. The capacity of health and sickness is the same; of stillness and movement; of being raised up and of falling down. But one of these must be good, and therefore the energy which determines which of these contraries shall have effect must be better than the faculty or capacity. Two consequences follow. The energy is that which makes things be evil which have only the possibility or potentiality of evil in them. Secondly, in those things which are primary and eternal there is no evil, no fault, no decay; the capacity for these lies in nature. The importance of these two axioms will be felt by every moral and theological student. Another more doubtful proposition, one which has been extensively applied in another direction, is added respecting *discovery*. It is that discovery means the bringing things into energy which exist potentially; because knowing is an energy.

This book concludes with another reference to the relation between truth and being, falsehood and not being. Truth and falsehood being the accordance or discordance of our judgment with the actual state of things, there are three cases which may fall under our notice. First, things always united and inseparable, or things always separable and never united. Respecting these the judgment must be uniform; the same will be truth in all cases, falsehood in all cases. Secondly, things which may be either separated or united. Here comes in the possibility of that being true to-day which is false to-morrow, true under one aspect which is false under another. Thirdly, things perfectly simple, things admitting neither of division nor combination. To these the words true and false do not apply, but merely knowledge and ignorance. You either know such things or you do not. Respecting these there is no mistake, no deception possible; but merely the presence or absence of knowledge. All substances which exist in energy merely and *εν δυνάμει*, are of this character; they are analogous to the sensible objects whose existence you ascertain by touch or sight; the want of touch or sight, not a false opinion, excluding them from you.

In the ninth book we come again upon the question of unity. The name One is used, he says, in four ways. It means that which is *continuous by nature, a whole, an individual thing, that which is predicated of a whole*. The general sense of the indivisible is common to all these. And again unity in any of these senses we may attribute to some particular substance which is inseparable in place, in form, in thought, as well as to some actually indivisible whole. The fundamental notion of unity he conceives to be that of a measure to quantities; without such a measure quantity is inconceivable. There may be something actually indivisible, there may be that which is indivisible to our senses, an actual unity in form, and a supposititious unity in matter. Each will bear the name, because each will be used as a measure. The need of such a measure, he asserts, in opposition to the Protagorean notion of man being the measure of all things, which he treats as a silly truism, putting on the form of a paradox, and producing the effects of a falsehood.

The existence of a distinct absolute unity is denied on

precisely the same ground as the existence of a distinct absolute substance. The one is always some one thing or nature. In colours, if you suppose them all to originate from white, white is the one. In voices, the elementary vowel, and so in all other cases. Of course, then, the Ionic attempt to discover some matter, such as air or fire, which shall be unity, is as unreasonable as the Parmenidean, Pythagorean, and Platonic to invest unity itself with a formal and separate character.

"The one" is the undivided, or the indivisible; this is the primary notion of it, to which all others may be reduced. "The many" then will mean the divided or the divisible; from which, as more cognizable by the senses, the one will be inferred. The question occurs next, how the one and the many are opposed to each other; whether the "many" and the "few" are not equally opposed, and whether, if this be the case, unity is not merely an element of plurality. This question introduces a discussion respecting the different modes of opposition; the opposition of contradiction, of things in relation, of privation, of strict contrariety, *κατ' ἀντιφασιν, τῶν πρὸς τι, κατὰ στερησιν, κατ' ἐναντιωσιν*. Possibly there has been some confusion of different lectures or reports in this part of the book; for in the lengthened explanation we seem to lose sight of the original subject. Our readers cannot fail to have remarked how much the idea of a "law of opposition" in things entered into all Greek speculations, so as to seem to many the foundation of them. Aristotle contemplates the subject from the logical side; the forms of opposition which he discovers in our minds determine his view of the actual opposition which exists in nature. And in this way his remarks on this point, though apparently irrelevant, throw considerable light on his doctrine respecting unity. What our understanding wants in order to explain to itself the existence of multitude, this he called "the One." Unity was therefore, in his mind, identical with Singleness.

In the next book, which is for the most part a recapitulation of puzzles and solutions already given, (not, however, to be passed over on that account, for Aristotle's repetitions of himself, or the reports of his different pupils, generally clear away many difficulties, and here, especially, the remarks on the nature and limitations of the primary philosophy and his confutation of the two cardinal sophisms of Protagoras are, in many respects, more complete than those in the third book,) we shall notice merely his analysis of Motion and his remarks on the idea of the Infinite. Motion is neither an energy nor yet merely a potency; but it must be contemplated, alternately, as each. A lump of brass is potentially a statue; the energy which is to make it one is in the mind of the sculptor. The motion, *i.e.* the transition from its condition as brass to its condition as a statue, is not found in the brass, neither is it found in the mind; it is that which gives the potentiality of the brass its meaning and connects it with the energy. Or to express this in a formula, "Motion is the entelechy (the perfecting power or principle) of the potential as potential." He admits the difficulty of finding an expression for this idea, but he shows, by an examination of previous attempts, that his own, however awkward, is the only one which is satisfactory.

On the subject of the Infinite, which had so much exercised the minds of previous Greek speculators, and had been resorted to as an ultimate solution of so many difficulties, he aims at no precision of language. By its

Moral and
Metaphysical
Philosophy.

Moral and
Metaphy-
sical Phi-
losophy.

very nature it excludes precision. To bring it into a scheme, or regard it as a helpful definition of nature or the universe is, in his judgment, absurd; it can only be looked upon as marking the *ne plus ultra* to which human thoughts and inquiries can reach, or, at least, have already reached. The limitations by which alone you are able to deal with the subjects that fall under human cognizance, it excludes by its very name. His opinion on this point is characteristic of his mind, and it has an important bearing upon the history of metaphysics. Scarcely any more interesting question occupied the Greek mind than that which was at issue between the schools of Pythagoras and Xenophanes, whether it is more true and reverential to speak of God as the *το πτερας*, or as the Infinite. Aristotle's concluding remark on the subject of the Infinite should be quoted for the casual light which the latter clause of it throws on his idea of Time, an idea which the student of modern philosophy has so much need to reflect on:—*το δ' άπειρον ου ταυτον εν μεγέθει και κινήσει και χρόνω ως μία τις φύσις, άλλα τὸ ὑπερον λέγεται κατὰ τὸ πρότερον, οἷον κινήσις κατὰ τὸ μέγεθος ἐφ' οὗ κινεῖται ἢ αλλοιούται ἢ αὐξεται, χρόνος δὲ δια τὴν κίνησιν.*

Book eleventh opens with an attempt to ascertain the number of Causes or first principles. There is in every sensible substance a capacity of change: these changes are four: changes in respect of substance, of quality, of quantity, and of place. Generation and corruption are the names for the first kind of change, growth and decay for the second, alteration (*αλλοιώσεις*) for the third, transference (*φορα*) for the fourth. These are changes into contraries. But contraries themselves do not change; there must be something which undergoes the change from one to the other of them. This something must be *matter*. Being does not arise from not being; but being in potency is changed into being in energy; and being in potency is matter. Assuming this, there are three *ἀρχαί* or first principles; the two contraries Form and Privation, (*στέρησις*), and the Matter which passes from one to the other.

But Aristotle says that this enunciation is strictly applicable only to material things; in these the element (*στοιχείον*) and the principle (*αρχή*) are the same. You have heat, the *εἶδος*, cold, the *στέρησις*, that which has the potency of being either *ύλη*, the resulting substance, the flesh, bone, or whatever it may be. But in those things which are apprehended by the mind, another idea intrudes itself. Besides, the two opposites, health and sickness, and the matter, which is susceptible of both, you have the health-making art of the physician. The principle in this use of it acquires a double meaning which does not belong to the element. It must be contemplated both as the stationary Form and the moving Power. There must in a sense be four *ἀρχαί*, though only three elements. These conclusions have been, the reader will perceive, partly anticipated, but it is needful to repeat them here; for here is the link between Aristotle's Metaphysics and his Theology; this is the road, or at least one step of the road, by which he arrives at the conception of a First Moving Cause. To the unfolding of this conception the greater part of this remarkable book is devoted. We can but give our readers the results of an argument which Aristotle evidently felt to be the summing up of his metaphysical series. There must be an eternal, immovable Substance, which is at the same time the source of all movement. The primary notion of this substance is that it is an

Energy. The notion of potentiality is excluded from it, for the highest form of being is incompatible with the mere capacity of being. And seeing matter and potentiality are convertible terms, it must be immaterial. There is no refuge from the notion that all things proceeded from darkness and nothingness, except in this belief. Energy being anterior to mere potency, eternity must be predicated of the chaos or night out of which things are supposed to be formed, in a different sense from that in which it is affirmed of the Primeval Being.

We must attribute a continual negative existence to them, but a continual operative existence can only be attributed to the first cause. We want them to account for Corruption and Decay. We want the other to account for actual Existence and Life. Matter is in no sense a cause either to itself or to any other thing; and to a first cause we necessarily attribute self Causation. Other things impart motion, having first received it; this must be its own Mover. The next step in the apprehension of this being we obtain by the consideration of our own intellect and volition. There is an object of cognition or thing to be known, an object of volition or thing to be desired. By these respectively the intellect and the volition in us are set in motion. That which appears good to each understanding or will actuates that; that which primarily actuates must be that which is good. But in this we discover the union of the faculty of knowledge with that which is to be known, the union of the faculty of will with that which is to be desired. Thus self-contemplation and self-delight must be the essentials of Deity.* By other processes of reasoning he arrives at the conclusion that the Being must be without parts, (*αμερής*), without passions, (*απαθής*), our readers will perceive the change of gender, and will easily believe that *τὸ θεῖον* is the more common antecedent than *ὁ θεός*, and subject to no vicissitude. (*ἀναλλοίωτον*.)

We then approach the grand question, whether there is one such cause, or many. In nothing is the difference between Aristotle and his master more remarkable than here. We have seen with what tenderness Plato treated the mythology of his countrymen, not from cowardice, but because he felt that it contained a latent truth for which no philosophical abstractions or generalities could offer a substitute. Aristotle having satisfied himself that the argument was in favour of a one cause, sweeps away all notions which interfered with it, considers the gods whom his country worshipped as derived from certain astrological notions, and as setting forth the secondary sensible substances which proceed from the first immaterial cause.

With equal decision he denounces (upon this new ground) the different philosophical schemes which had been substituted for the old cosmogonies; attributing to them these two common vices, that they had acknowledged an antithesis and contradiction in things, but had not taken account of that third element, matter, which is the only explanation of the evil and disorder in

* We must quote the fine passage in which this argument is summed up. *Ἡ δὲ νόσις ἢ καὶ αὐτὴν τοῦ καὶ αὐτὸ ἀρίστου καὶ ἡ μέλιστα τοῦ μέλιστα. αὐτὸν δὲ νοῖ ὁ νοῦς κατὰ μεταλήψιν τοῦ νοητοῦ νοητός γὰρ γίνεταί διγγάνων καὶ νοῦν, ὥστε ταῦτον νοῦς καὶ νοητόν. τὸ γὰρ δεκτικὸν τοῦ νοητοῦ καὶ τῆς οὐσίας νοῦς. ἐνεργεῖ δὲ ἔχων. ὥστ' ἐκείνο μάλλον τοῦτο ὁ δοκεῖ ὁ νοῦς εἶον ἔχειν καὶ ἡ διαφορά τὸ ἥδιστον καὶ ἀρίστον. εἰ οὖν οὕτως εἴ ἔχει ὡς ἡμεῖς ποτέ, ὁ θεὸς αὐτὸν, θαυμαστόν· εἰ δὲ μάλλον, ἔστι θαυμασιώτερον. ἔχει δὲ ὧδ'. καὶ ζωὴ δὲ γε ὑπάρχει. ἡ γὰρ, νοῦ ἐνεργεία ζωή, ἐκεῖνος δὲ ἡ ἐνέργεια· ἐνεργεία δὲ ἢ καὶ αὐτὴν ἐκείνου ζωὴ ἀρίστη καὶ αἰδώς. Met. xi. 7.*

the universe, and that they had substituted many original principles for the one.

In the two last books their doctrines (respecting ideas and numbers) are again discussed at great length, and with Aristotle's wonted ingenuity. It cannot be expected that we should go over arguments to which we have so often adverted, and which we are less anxious to present fully and formally than to fit our readers for studying them in the places where they occur. But we may take this opportunity of remarking, that the continual renewal of these discussions with the Platonists and Pythagoreans is very important in helping us to determine the nature and connection of these particular treatises as well as the character of Aristotle's whole mind and system. It is evident that he felt the refutation of these opinions, and the substitution of something else for them, to be in a manner the business of his life. At all events, it was the needful preliminary to all his more positive proceedings; while his mind was haunted with these notions, the system, physical, metaphysical, or moral, which he proposed to rear, had, it seemed to him, a dubious and infirm foundation. We look, therefore, upon the metaphysical treatises (whether capable or not of being reduced into a formal sequence and unity) as having this subject for their centre. To show what ideas are not, and what they are; to establish the doctrine, that the *εἶδος* is not distinct from the particular individual substance—existing apart and connecting it with some other higher substance, but merely its inherent form; to connect the *εἶδος*, which is the constituent principle of each thing, with the *ἐνέργεια*, whereby it is called into existence, and thus to make the same answer satisfactorily to the two Greek inquiries respecting the nature of being and origin of matter; to explain the nature and conditions of the *ύλη*, and by depriving it of all intrinsic substantial properties, and reducing it into a mere potency, practically to get rid of the old Ionic investigations; then finally to hint at a principle of which his moral writings are the full exposition, that the final cause or the *οὐ ἐνεκα*, is also connected with the *εἶδος* and *ἐνέργεια*; that the good or purpose of each class of substances is known when we know what its nature and proper energy are; this is the object at which he is aiming most consistently amidst all his windings and recapitulations in the books of metaphysics. But this object is connected, on the one side with *Logic*, on the other (as the scholiast is so anxious to inform us) with *Theology*. Though we have not seen our way to adopt Ritter's method of identifying the logical treatises with the metaphysical, (a plan inconsistent with the very words of the third book,) though, as it seems to us, we should sacrifice by such a course much insight into the habits of the philosopher's mind, and the growth of his opinions, which we obtain by seeing them distinctly, and yet acknowledging the most intimate connection between them, we believe Aristotle to be primarily and at heart a logician; to have become thoroughly enamoured of the forms of logic, and convinced that they supplied a satisfactory exposition of the facts of the world; and then gradually to have worked out in his mind an ontological system, which gave the rationale of those forms and interpreted their relation to different phenomena. Now, if it be true, as we have maintained, that the *mathematician* has another set of laws, discovered to him in the course of his inquiries, from those with which the logician is conversant, we need not be surprised either that the arguments of Aristotle against Ideas should

be so constantly mixed with allusions to the Pythagorean study of Lines or Numbers, or that that study should actually have been the *base* of the principle which he is endeavouring to subvert.

It is on all accounts a more important inquiry how *theology* became interwoven with either set of speculations. We think it cannot be denied that the recognition of an absolute being, of an absolute good, was that which gave life to the whole doctrine of Plato, and without which it is unmeaning; that on the contrary, it is merely the crowning result, or at least, the necessary postulate of Aristotle's philosophy. In strict consistency with this difference, it was a Being to satisfy the wants of man which Plato sighed for; it was a first cause of things to which Aristotle did homage. The first would part with no indication or symbol of the truth that God has held intercourse with men, has made himself known to them; the second was content with seeking in nature and logic for demonstrations of his attributes and his unity. When we use personal language to describe the God of whom Plato speaks, we feel that we are using that which suits best with his feelings and his principles, even when, through reverence or ignorance, he forbears to use it himself. When we use personal language to describe the Deity of Aristotle, we feel that it is improper and unsuitable, even if, through deference to ordinary notions, or the difficulty of inventing any other, he resorts to it himself.

The light which the metaphysical treatises throw upon this point makes them an important introduction to Aristotle's ethical system.

We might have concluded from his *Dialectics*, that he utterly rejected the Platonical doctrine of Ideas as a scientific exposition. But it would not follow that he should discard that belief in some ideal of excellence which had impregnated all mythologies, and had never been banished from the hearts of men. But the Aristotelian conception of God as a ground of nature, simply, leads us at once to feel that no recognition of his perfection can have the least connection in his mind with a scheme of practical life and conduct. We feel that it is not with Plato, or any philosopher who had attempted to give the rationale of men's dreams on this matter, he will feel a want of sympathy, but that he actually has not discovered in himself, and does not recognise in his brethren, the want which all ages had been contriving in so many forms to express. And then it becomes an interesting question, what will be the groundwork of the Aristotelian ethics answering to that *Theology* which is so obviously the foundation of the Platonic?

The answer to this question brings us to a very important treatise of Aristotle which embodies more of what has been commonly called metaphysics in our day, especially here and in Scotland, than the works professedly bearing that title. We mean the three books *Περὶ Ψυχῆς*. The first of these books is occupied as usual with an examination of previous theories on the subject. He despatches very elaborately the different notions respecting the soul which Democritus, Empedocles, or the Pythagoreans had encouraged. He shows why we can never be satisfied with calling it motion, or the principle of motion, the primary element or number. He then proceeds in the second book to develope his own doctrine. The soul belongs to the category of entities. It has then, of course, a matter and a form; the matter here, as elsewhere, coincides with its *δύναμις*; the form is (*εἰτελεχεια*.)

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

The soul is neither of these separately, but the result of both. There goes to the forming of sight the energy of vision, and the faculty of vision, and there is, in addition to both, an organ, an actual eye. What is true of this sense is true of the whole substance of which it may be said to form a part. The soul, possessing both its energy and its faculty distinct from the organ through which both are manifested, does yet require such an organ. The soul is not a body, but neither is it without a body. Generally it is the distinction of a living creature, (*ζωον*), that it has a *ψυχη*. But all living creatures have not a soul exercising the same *δυνάμεις*. We may define all the faculties which can exist in any living creature to be these: first, the faculty of receiving nourishment; (*θρεπτική*;) secondly, the faculty of sensation; (*αἰσθητική*;) thirdly, the faculty of motion in place; (*κινητική*;) fourthly, the faculty of impulse or desire; (*ορεκτική*;) fifthly, the faculty of intelligence, (*διανοητική*.) The threptic faculty is the lowest of these, and is present in all cases. The soul, therefore, as endued with this one faculty, may be attributed to vegetables. Wherever any of the higher faculties are present, there all the lower will exist also. Under each of these heads a very interesting discussion arises respecting the character and limits of the particular faculty. The question, for instance, under the first head is, whether the life in each plant or thing must be considered as the active or only the passive instrument in self-sustentation? Under the head of sensation many more complicated points arise, and Aristotle enters into the whole theory of the subject, examining the operation of each sense in detail. This, it may be remembered, is the discussion which is carried on with so much liveliness and profundity in one part of the *Theætetus*. The opinions there attributed to Protagoras (and so far as the doctrine of sensation goes, apart from its moral consequences, not denied by Plato) is nearly the same as that maintained by Aristotle. Sensation is neither in the organ of sense nor in the object, but is generated between both, and is the effect of the medium through which they hold communion with each other. The question as to the motive faculty involves us at once in a consideration of that which is higher than itself. Movement must depend upon impulse. This will be true in all creatures. And in spite of the effect of the appearances which are produced upon or by means of the senses, in generating impulses or desires, we must not impute a governing power to sensation; we must rather think that the nature of the faculty of impulse determines how these shall influence it, than that it is determined by them. It would seem then, that each creature has a nature, which is expressly seen in this faculty of impulse. Wherein then does man differ from other creatures? Neither, it would seem, in the absence of this impulsive faculty, nor in its being less properly his nature than it is that of other animals, but rather in his having the dianoetic faculty to direct it and act with it. In the coincidence and conspiracy then of these two faculties will consist the true nature of man. Thus, then, the soul may be considered as containing three portions, logically not materially separate, one absolutely without reason, the other rational, another participant of reason.

Ethics

In this psychological system we discover the root of the Aristotelian ethics of which we were in search: they begin in psychology and terminate in Politics.

Aristotle informs us, very early in the *Nichomachean* treatise, that he looks upon politics as the *ἀρχιτεκτονική*

VOL. II.

ἐπιστήμη, and ethics as an introduction to it. The two, therefore, are not identified in his mind as they are in Plato's; it is quite possible, nay necessary, to treat of them distinctly. According to his uniform method, he seeks for the grounds of combination and society in the nature of man. He cannot tolerate Plato's simplicity in admitting outward necessities and accidents to be the *occasions* of it; for this simplicity necessarily involves another proceeding which seemed to him not simple but pregnant with all Plato's idealism, that of supposing some higher Unity than that which is expressed in the character of any particular society to be involved in the constitution of society itself. A principle of equality and adjustment is that which seems to him to pervade all things, to be in a manner a law of the universe, and to be especially the secret of human order and government. The like principle, taking a different form, is the mainspring of his ethical system. Virtue lies in a mean, in a sense it may be said to be a mean, so that, on the one hand, government, which is also a mean, is naturally occupied in sustaining the virtue of particular men, and on the other, this virtue is itself the great conservation of government. This observation ought to be made, as without it the connection between these two spheres, which is as much acknowledged by Aristotle as by his master, will not be apparent. Many difficulties also will present themselves to the reader as insurmountable, if he looks at the ethics as an entire system, and do not remember that a directing educating power is for practical purposes presumed to reside in a governing body, the functions and nature of which have not yet been defined. But we are not to suppose that Virtue, or the attainment of this mean, is in Aristotle's judgment the formal object at which either the life of each particular man, or society at large, is aiming. When once the notion of an absolute good, which "those dear" and troublesome men, the Platonists, had introduced, was taken out of the way, there remained one obvious and generally admitted end of all human desires and searchings. HAPPINESS is emphatically the human *τέλος*. But if human, then the definition of this happiness must be sought in that which is peculiarly the characteristic of the human class. It cannot exist in any of those powers or faculties which are common to it with other classes, not therefore in the threptic or the æsthetic powers merely and chiefly. And any how, it must be in some exercises or energies that it will consist, for in these the soul or life of every creature makes itself manifest; it must be then in the energies of our best and highest nature, exercised not at intervals, but through a whole life, a life possessing so much of external prosperity as shall permit them a free scope. But all energies must have a certain direction; the right direction of its energies constitutes the *virtue* of each class. What then will be specifically the human virtue? It must of course be in the man, and, according to our psychology, the *ορεξίς* (the impulsive faculty) is the constitutive faculty of the human soul, though its excellence consists in its subjection to the dianoetic faculty. Virtue then will imply the presence and the harmony of both these; still it will be found most positively and characteristically in the former. It must be then a habit. But of what kind? To what does it point? What is its aim, seeing that an absolute good, or an ideal, is out of the question, and that happiness cannot be the aim, because it is the very nature of happiness which we are now resolving into its elements? We are

Moral and
Metaphysical
Philosophy.

not, Aristotle says, to trouble ourselves about scientific accuracy in our definitions; our purpose is purely practical; we want to form an actual man of a certain character, not a theoretic man. Well, then, practically speaking, excess is in every case that to which you attribute mischief and derangement. There is an excess called Timidity, and an excess called Fool-hardiness, an excess called Prodigality, and an excess called Narrowness or Avarice. But the extremes suppose a mean. This is the end at which our habit aims. Virtue generally lies in this. But we are aiming at action; and actions are not general, but specific; how then shall we arrive at the notion of specific virtues? Their species will be determined by their distinct objects. Certain tendencies and habits will be conversant with external pleasures. Certain others with passions of the mind itself; in each case it will be found that the practical purpose defines the virtue. But though a general description may be given both of the excesses and the means which correspond to them, a description which will be really applicable in all cases, it must ever be remembered that the excess itself may be different for each man, actually different according to his actual circumstances, different in its effects and influence upon him according to his greater proneness to one side or the other. For instance, liberality of course will be practically a different quality in the rich man and the poor man, and the temptation to profusion will be that which is to be most resisted by one, to meanness by another. Virtue will be therefore in a *mean*, that is one to us, and not one that can be absolutely and invariably ascertained by rule.

Hence it follows that this habit supposes the exercise of a faculty of choice or predetermination. But what is predetermination? Is it the same as the act of willing? Clearly not; that has reference to ends, this to the choice of means and the attainment of ends. But it implies a right end, and a right determination of the will to that end. It may be called *ορεξις βουλευτική*, (the reader will observe how steadily his psychological axiom which we have spoken of is kept in view throughout the scheme.) But to what cases will this will or counsel refer, and how far is it dependent upon ourselves? Clearly we do not consult about things absolute or eternal, nor about things within the sphere of accident. What remain are all such things as are done by us or with our concurrence. Now of such some may be doubtless taken from under our control by actual violence practised upon us; such cases give rise to various questions of casuistry, as to the course which a virtuous man will take, whether he will submit to do wrong or to die, each of which must be determined on its own merits. With respect to ordinary cases, the doubt arises, whether inclination is not itself a force upon the will and on the reason both. Such a notion Aristotle disposes of, first, by the remark that an influence upon the impulse or will cannot by any reasonable man be confounded with a force by which its operations are hindered; and secondly, by admitting that an incapacity for any particular action may doubtless be produced in any man by these influences, but that this incapacity is itself the result of a previous habit which need not have been thus formed. Habits then are in our own power, actions not always. Having settled these foundations, the particular ethical virtues come next under his consideration. Here lies a field for the exercise of his always acute and often delicate habits of obser-

vation. It is alien from the temper of mind which Shakspeare has wrought into us, to contemplate any character as the mere developement of any single specific quality. We do not like to hear of a man as the Magnificent, or the Magnanimous, or the Modest, or the Temperate, or the Just. But, doubtless, there was something in this which suited well with Greek habits. The Aristides, Themistocles, Cimon, if they had not any of them a distinct purpose of realizing a particular form of character, yet drop more readily into certain moulds than the traditionary characters in the story either of ancient Rome or modern Europe. How a similar tendency was revived at one period in Christian society, and how its revival was connected with a scholastic reverence for Aristotle, we may have to notice hereafter.

Among these virtues it behoves us especially to take notice of two, because they throw some light upon the entire system, and upon ethical inquiries generally. The first is Justice. (*δικαιοσύνη*.) Is not this virtue itself an abstract of all the virtues? We have seen how Plato answers the question in his *Republic*. Aristotle treats it differently, yet so as to make us see how much he had felt the influence of his master's ideas, even when he rejected them. In one sense (he says) *δικαιοσύνη* may indeed be said to be a complex of virtues. For as it is the habit which mainly disposes to allegiance to the laws, and as laws prohibit excesses of all kinds, and encourage virtues of all kinds, this will have respect to them all. But yet there is such an offence as Overreaching, and there must be a specific virtue answering to this. But the specific virtue will bear relation to the general. Inequality, in matters appertaining to property, will be the evil. Evenness or equality will be the virtue. This evenness or equality implies, on each side, an excess, a more and a less; a more and a less, however, in reference to given persons. The conservation of the right proportion or relation of things to persons, and the restoration of the balance when it has been violated, is then that at which this virtue especially aims. Take away the restriction to property, and this virtue would seem to be in a remarkable manner the very Virtue of Virtues; so emphatically is it the preserver of the mean. But that very restriction makes it more difficult to tell how far this virtue belongs to the individual, and how far to the state, so that *δικαιοσύνη*, though bearing a much more limited meaning, becomes, to our author as to his master, a kind of debateable ground between the two regions. At all events *δικαιοσύνη* must be looked upon as characteristically the ethical virtue of a statesman.

The other virtue we must speak of is *σωφροσύνη*. As this is opposed to *ακολασία*, and involves the general notion of an even habit of mind not overcome or disturbed by sensual desires, it might seem to include within it *εγκράτεια*, or self-restraint. But as in the psychology of Aristotle the soul consists of a rational, an irrational, and a quasi-rational part, the quality which implies a control of the irrational or merely animal nature, will not necessarily be the same with that which concerns the quasi-rational, that is, the passions and affections to which the will is subject. As the name *σωφροσύνη* is given to the first, the name *εγκράτεια* is used for the second. Hence a curious consequence. This self-government seems something distinct not only from the peculiar *αρετή* which has reference to sensual desires, but even from *αρετή* itself. That has its chief seat in that nature or impulsive faculty over which *this* is sup-

Moral and
Metaphysical
Philosophy.

Moral and
Metaphy-
sical Phi-
losophy.

posed to rule. We are somewhat puzzled, therefore, after going through our catalogue of virtues, to find a book opening with the remark, that there are three moral states to be avoided, *κακία, ἀκρασία, θηριότης*, and three good states corresponding to these, *ἀρετή, ἐγκράτεια*, and a certain divine excellence as much transcending ordinary humanity as *θηριότης* sinks below it. This result will appear inevitable to any one who reflects upon the system; that which is conservative of virtue must in some way be distinct from virtue, but we must acknowledge also that it considerably impairs the symmetry of a design otherwise singularly complete.

Before, however, Aristotle touched upon this conservative power, which, of course, is connected with the purely ethical part of man, it was needful for him to expound more distinctly than he had done in his psychology the nature of these dianoetic faculties to which such important functions are committed. He begins with reaffirming the position so often insisted upon, that the *ορεξις*, and the *διανοία*, must co-operate in order that any good moral act may be the result, or, as he expresses it, with neatness and in more strict accordance with his own notion of the *διανοία*; that which is affirmed or denied by the one should be that which is pursued or avoided by the other. Now the soul, he says, may affirm or deny truly in five ways, by *τέχνη*, by *ἐπιστήμη*, by *φρονησις*, by *σοφία*, by *νοῦς*. *Τέχνη* is what in modern language would be called the creative power or faculty, the poetic organ in its highest and lowest sense. *Ἐπιστήμη* is the converse of this. It deals with that which cannot be otherwise, it does not fashion anew but perceives; what it deals with are universals not particulars. Aristotelian science is, as we have seen already, conversant with conclusions not premises; but there must be some faculty which deals with premises, a tact, intuition, or spiritual sense, this is *νοῦς*. The sphere of this faculty would seem to be very limited, for as it is bounded on one side by *ἐπιστήμη*, it is bounded on the other by *σοφία*. This faculty, we were told in the *Metaphysics*, was conversant with *ἀρχαί* or principles; it might therefore seem to cover the whole ground which is assigned to *νοῦς*. But that which affirms things to be so and so without a reasoning process, is undoubtedly distinct from that faculty which, through long and winding labyrinths, searches for causes. Now, when the *νοῦς* is said to deal with premises, the first kind of operation is indicated; when the *σοφία*, the second. *Φρονησις*, the last of the five, is different, and yet has something of the character of the preceding. Its sphere is with the altering and the alterable, like *τέχνη*, but it is not productive or creative, but perceptive and distinguishing. So far it resembles *ἐπιστήμη*, differing from it wholly in its subject-matter. It has a quickness of tact like the *νοῦς*, but this is merely the result of practice and experience. It is, therefore, like *σοφία*, a laborious investigating faculty. Yet its end is not speculation, but practice. The *φρονιμος* or practical experimental man, therefore, is contrasted with the *σοφος*, or the meditative speculative man; though it is not denied that *σοφία* may assist and be usefully connected with *φρονησις*. From this analysis it is evident that this last quality is especially that which, in combination with a right *ἦθος*, or a proper condition of the impulsive faculty, produces virtue. The doctrine of Socrates, that virtue is *φρονησις*, (a doctrine by the way which is somewhat carelessly stated, for the real Socratic doctrine treats virtue as *ἐπιστήμη*, the knowledge of what is absolutely good, prudence being only a guardian

faculty to preserve the soul when seeking that knowledge from the seductions and confusions of sense,) this doctrine is said to form only one side of the truth; *φρονησις* is not virtue, though virtue cannot exist without it.

We have seen that *δικαιοσύνη* does to a certain extent occupy the same position in the Aristotelian and in the Platonic system as a link between morals and politics. But Aristotle could not help perceiving that this quality, under the conditions which he had imposed upon it, explained but very imperfectly the connection of human society with the life of the individual. This dry and hard principle of distribution, commutation, and rectification, could never be substituted for the music of Plato's *Commonwealth*. Reflecting on this difference, it seems to have struck him, that in the idea of Friendship we have that which fills up the void, and that Friendship together with justice constitute the social law. Regarded in this light, Friendship occupies the most important place in a system of ethics, which is always looking onwards to Politics. And we cannot wonder that Aristotle should have devoted two elaborate books to the consideration of it. Any one who is acquainted with the traditions and with the mythology of Greece must be aware how much the Greek mind was occupied with this subject. Here, as elsewhere, physical and moral thoughts became intertwined, and the same language was used to explain the law of sympathy between the skies and earth, and that between man and man. Aristotle is careful to disengage himself from these ambiguous phrases, which he had not perhaps imagination enough to perceive were more than metaphors, and fixes his mind upon friendship as one of the essential conditions of our nature to which the very existence of communion must be referred.

This being assumed, he has no hesitation in setting aside many popular notions of friendship as giving a wholly inadequate view of its nature. The doctrine which refers friendship either to Utility or to Pleasure as its ultimate foundation, he rejects not with sentimental indignation, but as being at variance with facts and reason. The transitoriness of such friendships, and their dependence upon accidents, are arguments as much to the practical man as to the philosopher, that the essence of the quality is not to be discovered in them. The friendship of good men for each other must then be that from which we are to deduce the nature of friendship itself. Here, and here only, we learn the conditions, or even the possibility of friendship, for, properly speaking, it is not possible, except upon the supposition that one man can really delight in another, and love him as himself. A politician seriously reflecting on the existence of society, must feel that a principle is at work among men which can be only defined in these terms; that all the imperfect appearances which it presents in the world, so far as they are imperfect, make its meaning less intelligible; that, supposing selfishness absolute, it could not exist at all, and that the highest form in which it exhibits itself is the test of its character. These important conclusions are stated again and again, and with the greatest precision, by Aristotle. On the strength of them he affirms, that the idea of equality or proportion is as much discoverable in friendship as in justice; only that in justice the worth of each object is the first consideration, its fitness to us the second, in friendship, fitness or suitableness the first, worth the subordinate. On the same ground he maintains, that friendship is to be seen in its true operation, not in

Metaphy-
sical Phi-
losophy.

clubs, or societies, or partnerships, where men associate for some specific object, (though here also Justice is required as its assessor and its complement, every kind of society implying a law to regulate it, as well as a motive to form it, a principle of government as well as of concord,) but in a *polity* of which all these must be considered as portions. An inquiry, therefore, into the different kinds of government becomes connected with an inquiry into the law of friendship.

In this passage we discover how much Aristotle surpassed Plato in his apprehensions respecting the nature of relationships, while he fell so far short of him in every thing that concerns the absolute. He discovers in the relationships of father to son, of husband to wife, of brother to sister, three primary forms as it were of friendship; and the grounds of the three kinds of government to which all others may be reduced, Monarchy, Aristocracy, Timocracy, and of which the three corruptions are, tyranny, oligarchy, democracy. Under each of these true forms of government friendship and justice will be found existing and mutually sustaining each other. Friendship, however, will take its peculiar form from the form of the society. It will be the friendship of patronage and of reverence in a monarchy. It will have the conjugal model in aristocracy, one party being respected as the superior in worth, and retaining that respect only while he asserts dominion on that ground. The fraternal type of equality will be preserved in all friendships under a timocracy. On the other hand, in the depraved forms friendship will be depraved and weak; and in a tyranny, which he regards as the worst of all, because the corruption of the best, both it and justice will disappear, because subjects are there regarded as animals, and as such incapable of these human qualities. The existence of this law of sympathy being then established as one of the two necessary conditions of human fellowship, and virtue being shown to be the necessary condition of friendship, Aristotle proceeds to solve a great many questions of very deep and practical interest. The most important of these turn upon the relation between friendship and self-love. In what sense is friendship a part of self-love? in what sense opposed to it? As the notion of pleasure or utility had already been separated from friendship, it is obvious that the vulgar notion of self-love must be separated from it also. Still ordinary language intimates that there must be some analogy between the two ideas, and it seems hard to arrive at any higher description than this, that the friend is loved as another self. May not the difficulty then be solved thus? may not self-love be itself distinguished from all associations of profit and loss? and may we not affirm that the wise and good man is the true self-lover, the person who alone is at one with himself, and can take pleasure in his own company? If this be so, it would not be correct to seek for the ground of friendship in self-love, it would be more correct to say that they mutually illustrate each other. Only the man who has the capacity of friendship will have himself for a friend, and only he who can enjoy and love himself, is capable of enjoying and loving another. These two books on friendship are certainly not the least profound in Aristotle's writings, and to the general reader they will be far the most delightful. From this subject we proceed, in the tenth book, to the question of Pleasure; what it is, how far, according to the doctrine of some philosophers, it is to be denounced as an evil, how far it is a

good, or connected with *the good*. Aristotle argues against many prevalent definitions of pleasure. He shows why it is neither a *κίνησις*, a mere movement, a *γενεσις*, the passage into a state, or an *αναπληρωσις*, the filling up of a want. He considers the universal longing of mankind a sufficient witness that pleasure is something real and worthy in itself, and not merely a means to some other end. An examination of the facts leads to the same conclusion. But it leads also to a refutation of the opinion, that pleasure can be made a distinct formal purpose of life. It is the flower or consummation of something else. The exercise of sight, the exercise of hearing, each brings its own appropriate pleasure after it. But the pleasure is connected with the energy or exercise, and cannot be severed from it. If then you would understand what pleasure is, and what are the highest pleasures, you must understand what energies are, and what are the highest energies. You cannot refer the last to the first, you must refer the first to the last. That energy, then, which is most appropriate to each creature brings the pleasure which is appropriate to that creature; "the energy of the soul, according to virtue," brings the highest pleasure to man. The pleasure which an act gives to him who performs it is the test of that act having become habitual to him, of his having acquired the character corresponding to that act. The man who delights in musical energies has become a musician. The man who delights in just acts is a just man. From this analysis of the nature of pleasure, the step is easy to a reconsideration of the meaning and nature of happiness, and so to a brief review of the whole treatise. Happiness he has found to be the end of man, and to consist in (not like pleasure, merely to be the effect of) the use of his highest energies. What then, on the whole, is the highest happiness? It is that of the contemplative man. If we can imagine what the life of the gods is, seeing it is absurd to attribute to them justice, because that has respect to contracts and conventions, temperance, because that implies temptations to which they cannot be exposed; and so of most of the other acts which preserve the mean for man, we must believe it to consist in contemplation. But then for the attainment of this celestial life in those who can attain it, there is need of early discipline and education. There is need that they should be trained to the avoidance of those extremes in which evil lies, and to the exercise of those virtues which are the only conditions of, and preparations for, the contemplative happiness, though it transcends them. And for the rest there must be a discipline to cultivate what capacities there are in them; or in case of resistance to such cultivation, to coerce and punish them. Here then is the field for the science of Politics. That science, Aristotle says, the sophists had resolved into a mere teaching how to talk and argue, but the foundations of it lie in ethical knowledge and ethical practice, and it must be worthless and rotten when these foundations are not discovered. This is the introduction to the book on Politics.

We can but give our readers a few hints to assist them in the study of this treatise, which, valuable and interesting as it is, can never bear the same relation to the other Aristotelian writings which the Platonic Republic bears to the other dialogues. Not, it will be evident enough from our former remarks, that the Politics of Aristotle are not most closely connected with his Ethics and his Ontology, but that they are connected with them rather as results and deductions, than as

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

being a principal and fundamental part of the design. The doctrine which has been set forth with so much diligence in the *Metaphysics*, of every substance presupposing a lordly energizing power, and a submissive receptive faculty or matter, re-appears again here in connection with the most obvious and outward facts. The relation of Male and Female is assumed as the first hint of the existence of society, and as containing the principle of it. The idea of fellowship implied in this relation involves another,—that of rule and subjection, which has its complete expression in the relation of Master and Slave. Compare these two relations with that relation in each man which has been explained in the *Psychology* and illustrated in the *Ethics*, between the reasoning power, the faculty participant of reason, and the mere animal nature, and you feel at once that the two explain each other, and set forth the condition under which society is meant to exist. Where the reason is developed and its magisterial authority acknowledged, the other faculty being in fellowship with and subordination to it, and the animal nature controlled and subjected, there you have as well the true condition of the individual man as the true condition of society, there the relations of husband and wife, and master and servant, will be preserved; they will not be arbitrary, but legal and orderly. In such a state of things only a polity is possible; yet, as this is the only true condition of each man, it is evident that a political state is his only proper and natural condition, every other must be anomalous. You find then the constituents of a polity in household, but a house is not therefore a miniature city; a city is not merely a collection of households; each has its own distinct nature and laws, though each alike has this characteristic—that in the human relations it consists, that in them you discover the end of its existence, and that all means and instruments are to be contemplated with reference to these. Economy is not primarily, but secondarily and accidentally, the management of the goods or property of the household, it is mainly the right ordering of the household itself. The slave is the connecting link between one branch of economy and the other; he must be considered as an instrument, and yet he must be treated as a man. A polity can be considered only as composed of freemen quite as much because a freeman only understands how to obey as because he only understands how to govern.

It follows almost necessarily from this view of the case, first, that the Platonic idea of unity should be as little heeded by Aristotle in his *Polity* as in his *Metaphysics*; that he should utterly abhor the attempt to embody that idea by abolishing distinct relationships, these being in his opinion the very foundation of society; that he should recognise all forms of government as good which have their ground in any actual relation, and all as evil which have become in any sense arbitrary; that he should therefore acknowledge, much as Plato did, three true forms and three departures from these; and that he should look on the democratical departure, the attempt to establish a society in which all should govern with at least as little complacency as the rest; that at the same time he should conceive that form from which this is a deviation, the form which treats all freemen as eligible to government, though not necessarily as participant of it, as his ideal. These seem to us the main principles of the book, which, being understood, the occasional difficulties and contradictions it presents will be less puzzling; its position, in

reference to the other parts of the philosophy, will be felt, and its value as a key to the political science of modern as well as ancient times will be appreciated.

losophy.

The Later Sects.

We should have been glad to notice another treatise of Aristotle, which is valuable in many ways, and especially for affording an interesting practical illustration of his scientific method and some important applications of his *Ethics* and his *Politics*; we allude to the three books on *Rhetoric*; but we must deny ourselves the pleasure of dwelling any longer upon the masterpieces of Greek philosophy—the books which really teach us what Greece was, and what work it was appointed to do in the world,—that we may pass into the company of certain teachers who have earned a reputation far beyond their merits, and have even been able to palm themselves upon the world as the genuine representatives of the wisdom of a country which had lost all its capacity of producing great men before they were born into it. Every part of our story thus far has testified that the political life of Greece was the main pillar of its speculative life; every thing which we have read would prepare us to expect that when that political life was departed, its speculations would become withered and heartless; either this must have been so, or there can have been no fellowship between earlier and later Greece; the laws which apply to the one must be entirely inapplicable to the other. We do not believe this to have been the case; we do not believe that our anticipations respecting the state of the Greek mind after its institutions and its freedom should be gone are in the least confuted by the existence of those sects which persons who read of Greece with Roman eyes are wont to speak of as *the Greek schools*. Nevertheless we do not deny that these sects were permitted to exist for certain useful purposes, and it is worth while to ascertain, as far as we are able, what these purposes were.

We have spoken of philosophy throughout as an attempt to find an explanation of facts—the facts of society, the facts of the individual mind, the facts of nature. These facts of course remain, whether we are awakened to perceive them or not. Savages are held together by the same laws which bind together civilized men; they have the same hearts and consciences, they have the same sun and moon shining upon them. But because they have never felt themselves in an order, because the feelings of relationship and obedience and law have never been awakened within them, therefore their own thoughts are a dreary chaos of fears and hopes, and all the universe only a medley of incoherent images, partly pleasant, partly fearful. Suppose that sense of an order withdrawn from a nation in a high state of outward civilization, from a nation whose members had a gorgeous past to look back upon, with native quickness, with a sense of hereditary power, with the means of material enjoyment, with faculties refined to make use of them, and how will the result differ from that which we noticed in the other case? It will differ thus: in place of a language hardly competent to explain a single combination of human feeling, or of outward phenomena, only expressing a certain vague consciousness of surprise, doubt, and awe, will be a language containing forms for every variety of feeling, for every kind of description; in place of a few lively scattered impressions, a whole harvest of observations and reflections

Moral and
Metaphy-
sical Phi-
losophy.

gathered in by previous labourers; in place of an acquaintance with one set of very limited circumstances, a pleasure in contemplating and comparing infinite diversities of circumstances. With these differences, what remains in common?—A hollowness, vagueness, absence of all feeling of reality, the sincerest man owning little else but a sense of endless confusion, and mourning over it; the insincere making that sense of confusion his boast, and glorying because he can explain all things by declaring that they admit of no explanation. Such is emphatically an age of scepticism, an age which does not feel that it has any facts to rest upon, which does not really desire to know what any thing means, which believes that nothing has been done or proved in past time, which wishes to create all things new, but which having no feeling or sympathy with what is created, is utterly unable to do more than invent a few new combinations and recast certain forms of thought and language, out of which the meaning has departed. Greece, after the age of Alexander and Aristotle, was emphatically in this miserable condition. When the Sophists undertook to prove that the words Right and Wrong meant nothing, they were confuted by the actual existence of a government based upon the acknowledgment of right, and by a conscience in every man that this government could not subsist against his own and his neighbours' selfish and violent inclinations unless it were upheld by some divine power. The philosopher might be puzzled to reconcile this faith with the strange, disorderly, and unrighteous acts which tradition had attributed to the gods of his country, but the faith itself never lost its hold upon his mind; he assumed it as a datum with which other facts were to be reconciled, and which was to be in some sense the explanation of them. Now there was the phantom of a government based upon mere power; the sense of the necessity of a divine Ruler was gone; the majority continued to practise the rites, and maintain, through fear or indolence, the traditions which implied his existence; the speculative man could look without trembling at the question—whether these rites and traditions meant any thing, and could, as it suited his temper or convenience, practise them punctiliously or ridicule them, or do both at once. In such a languid state of society all really active and energetic thought was impossible, all that was done for a time was to ask questions which had been asked before by earnest men with the hope of an answer, for the purpose of showing that no answer could be given; and then, when pure unadulterated scepticism became too weary or too painful, came a series of attempts to seize hold of some one partial observation or consciousness, and to make all the universe merely an exposition and expansion of that.

Pyrrho.

The person who always stands as the type and representative of the earlier and more complete scepticism of this period is Pyrrho, and this is nearly all that can or need be said of him; for it would be a waste of time, at least in such a sketch as this, to attempt to harmonize the different reports of his sayings and doings. There is nothing recorded of him which marks him out as an original or generative thinker, but enough to give us warrant for believing that he had more character than those who surrounded him, and was therefore able to express in words, thoughts and feelings which belonged to them as much as to himself. Given—the Socratic method of disputation, the doctrine respecting contraries which pervaded all Greek philosophy, and was brought

out with the greatest clearness and precision by Aristotle, the great saying, that—a man knows only that he knows nothing—given, these old and stable elements, and combining them in due proportions with the insincere, vapouring, indifferent habits of Greece in his day, and it is not difficult to construct a Pyrrho who shall embody all the notions and have a right to use all the formulas which are attributed to him and his disciples. The old question between the Sophists and their opponents—the question upon which all Greek philosophy turns, whether any thing is, or whether *is* and *seems* are equivalent words, was now practically decided in favour of that conclusion which Plato and Aristotle had in their different ways used the whole energies of their minds to confound. Pyrrho merely adopted in terms the opinion which every one else in fact held, when he affirmed that nothing could be affirmed, that all was appearance and opinion, knowledge a dream and impossibility. Of course a man who endeavours to carry out such a theory as this, and to make it consistent at least with what he feels in himself and in others, must fall into innumerable extravagancies and contradictions. But nothing is so extravagant and contradictory to a person who has given up faith, as to suppose that any thing can be known; every monstrous hypothesis must be tolerated rather than this. It is an obvious remark, but one which it is important for us to make in connection with what was said of Words when we were speaking of Socrates and Plato, that language must have utterly lost its power and reality before this kind of scepticism could prevail. As long as men believe that the words which they speak are not mere sounds, or gusts of air, the words Being and Knowledge must be felt to be witnesses which no disputation can get rid of; but for a language to subsist when the polity and morality of the nation which spoke it are gone, is utterly impossible.

The first indication that the Greeks had grown tired of utter disbelief, and were seeking somewhere or somehow for a resting-place, is furnished by the appearance of *Epicurus*. Pyrrho had discovered that man has nothing to do but to doubt; still he was constrained to admit that he is also obliged in some certain sense to exist. His own doubts had, in fact, so little interfered with the practical exercise of his animal functions, that he is reported to have used them for nearly ninety years. All, then, is not quite vacancy: a man has something to do, even something to think about; he may exist, and consider how he can exist with least friction from without or from within. This problem Epicurus set himself to solve. Was it a new one, one which had never presented itself to the Greek mind before?—Proposed in this way, it was certainly new. Socrates endeavoured to find out how men must live, but he never taught them to make out a scheme of life for themselves. Aristippus taught, that the end of a man's life was to please himself, but he had been content to let his cheerful easy nature shape itself according to the circumstances which he found. Plato had sought for happiness in the knowledge of that which is good and true; his inquiry was of course quite obsolete. Lastly, Aristotle had made happiness the end of life; but then happiness was with him an energy of the soul, to be put forth in conformity with a system of existing relations, impossible, except on the belief of our being a body politic in which each exists for the sake of all. The simple question, therefore, how a man is to make himself comfortable, may be said to have been now for the

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

first time propounded as the staple question of philosophy; and being thus propounded, we need not wonder that it should for a time hold quite exclusive dominion.

A man must be brought into a strange condition of mind before he can believe that the universe and all that it contains exist only that they may tell him how he is to be comfortable, but when he has once arrived at this condition it will be wonderful indeed if his ears ever catch any sound which is not an echo of his demand, or some fragment of an answer to it. We must not wonder, then, that the Epicurean, rising up in a sceptical age, and starting with the great principle of scepticism,—that nothing is, but all things seem,—should have become the greatest and most imperious of Dogmatists. With the most perfect sincerity, while denying the existence of truth, and the possibility of knowledge, he affirms his own conclusions to be irrefragable. Do you deny that all men like pleasure and dislike pain? This is his kind of inquiry, which as it means simply, do you deny that all men like what they like and dislike what they dislike? certainly reduces an opponent to very considerable perplexity.

But while we admit that Epicurus did present philosophy in a new form to the world by his method of stating its principal problem, we can by no means allow him any originality in his method of solving it. Aristotle had shown most clearly that if an absolute good be not the end of practical life, happiness must be its end. Epicurus could say no more; he could only find out some new criterion of what happiness is, seeing that, for the reasons we have already mentioned, Aristotle's definition of it must needs be unsatisfactory. But in seeking for this criterion he had no resource but to adopt the old sophistical dogma; he could only say that we must refer every thing to the standard of our sensations. No doubt he may have refined considerably upon this thought, for, in the first place, he had a body of formulas provided him by Plato and Aristotle on the subject of sensations; and secondly, he lived in an age in which thought was less active, but in which all that contributes to mere gratification, whether bodily or mental, was far better understood. It is a question which has been much, and we think very unnecessarily debated, whether, by making sensation his standard of happiness, Epicurus did, or did not, mean to encourage what is formally called sensuality. The testimonies of antiquity respecting his personal character are various, and the most modern criticism seems rather inclined to revert to the vulgar opinion respecting it, rejecting, certainly with good reason, the absurd and fanatical panegyrics of some French and English writers in the last century. Upon the whole, we are inclined to believe that Epicurus was an apathetic, decorous, formal man, who was able, without any great difficulty, to cultivate a measured and even habit of mind, who may have occasionally indulged in sensual gratifications to prove that he thought them lawful, but who generally preferred, as a matter of taste, the exercises of the intellect to the more violent forms of self-indulgence. And this life would, it seems to us, be most consistent with his opinions. To avoid commotion, to make the stream of life flow on as easily and uninterruptedly as possible, was clearly the aim of his philosophy. For this end it was advisable to avoid the pursuit of wealth and honours, it was better to abstain from extremely vehement enjoyments, but it was absolutely necessary to get rid of all superstitious fears.

How these were produced was therefore an important question for the founder of such a system. The answer to it led him much further than he at first intended to go. Naturally, Epicurus cared only for moral questions, that is to say, for such questions as related to the management of human life. With dialectics, either in the Platonic or Aristotelian sense of the word, he had no proper concern; for what had he to do with a science which distinguishes the false from the true either in things or words? In physics he took even less interest; the fixed order of nature is a painful weight upon the mind of a man who aims at adjusting a scheme for himself, and who disbelieves in any actual order and government. Theology, so intimately blended with both of these in the earlier systems, would have been still more resolutely banished from his. But then all these subjects must pass under his review, because from all of them conclusions had been derived which affect man's serenity and cause him dreams. A study answering to logic must be used to explain the origin of opinions, and why some of them must, for want of better epithets, be called false and some true. A man has certain sensations, and certain images are presented to him from without. The sensations are to be trusted, the representations are to be trusted: only in the exercise of some power by which a judgment is formed from these sensations or representations does error arise. These are corrected by referring again to the sensations, the only ultimate standards. Here again the originality of Epicurus consists, it will be seen, wholly in his omissions.

The relation between the senses and the visible representations which are set before them had been treated by Plato and Aristotle, each in his own method, with the profoundest skill and discrimination. Epicurus had only to avail himself of such fragments from the intuitive observations of the one or the rigid analysis of the other, as were consistent with the rejection of their principle that there is another and a surer standard than that which the senses supply. In physics Epicurus was still an avowed copyist; and any one who studies the rest of his philosophy may perceive that, as he adopted the theory of Democritus, simply because it was the one which it was most comfortable to hold, so he was guided, in many changes which he introduced into it, simply by the wish to get rid of some distressing fact which interfered with his moral speculations, and made his scheme of life less practicable. The idea of mysterious powers in nature had been one which had at all times haunted the Greek mind, and to which the speculations of the philosophers bore as much witness as the fables of the mythologists. With this thought was connected another, still more oppressive to the mind of Epicurus, still more interfering with the calmness and apathy of the true sage. It seemed that these powers were organized, that there were the vestiges of a scheme in nature, that there was something in them which answered to man's own powers of art and contrivance, while it controlled them. From these painful impressions there was one joyful refuge. The notion of the world being composed of atoms which had met in empty space, had united and disposed themselves into the light forms or heavy masses of which our senses take cognizance, at once relieved Physics of its connection with Theology. And since one product of these invisible atoms was that which had been called the soul of man, a new light dawned upon the moral system from this natural philosophy, a new confirmation of the great principle that man

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

is a machine which may, like any other, be regulated and adjusted to produce certain desirable results. One fault, however, there is in the doctrine of Democritus. His descent of atoms in a direct line savoured too much of a determinate purpose, a fixed law. Suppose them to decline a little from the line—a very little—and this charm is broken, and, what is better still, you have a method of accounting for the existence of choice and freedom in man. If it be true that Epicurus really anticipated an actual physical discovery in this speculation, it is a new evidence that the divinity which he supposed took no interest in human thoughts or designs, does sometimes shape them into a strange resemblance of what is true, when they are shaping themselves into the most grotesque forms of falsehood. On the whole, it seems unnecessary to attribute to the founder of this philosophy any deep and malignant design of undermining the foundations of human belief or human conduct. He was an entirely different man from the sophists of the former age, far less acute, but also far less wicked. The worst that can be said of him is, that he exactly caught the impression of a wretched emasculated age; the best that can be said of him is, that he showed some skill in combining the notions of former philosophers into the only scheme of doctrine which could seem to the men of such an age plausible or possible. One thing should be noticed, that if Epicurism is ultimately destructive of moral habits, it is not to these, but to science, that it sets itself in direct opposition. The Epicurean is essentially the unscientific man—it would be more correct to say the hater of science; a fact the more striking, because in modern days, when physical science has established itself in the world by another agency than theirs, the disciples of this school have sometimes affected to take it under their patronage, and even to boast of themselves as the exclusive promoters of it. Perhaps we shall find, when we come to speak of them, that they have departed more in appearance than in reality from that which is, in truth, the fundamental principle of their sect.

The Stoics.

The second great effort against the Pyrrhonism of this age is the Stoic philosophy. In speaking of this system, as well as of the last, we must endeavour to detach ourselves as much as possible from Roman associations and representations. To do this entirely is out of the question, for till these philosophies were adopted by the living minds of Rome, they can scarcely be said to have found their meaning. Still it is important to consider the form of the statue as it came from Greek artists, now no longer able of themselves to impart animation to their works, before it was embraced by the Italian Pygmalion. If we reflect how deeply the feeling of an intercourse between men and a race superior to themselves had worked itself into the Greek character, what a number of fables, some beautiful, some impure, it had impregnated and procured credence for, how it sustained every form of polity and every system of laws, we may imagine what the effects must have been of its disappearance. If it be possible for a man, it certainly was not possible for a Greek to feel himself connected by any real bonds with his fellow-creatures around him, when he felt himself utterly separated from every being but them. But the sense of this isolation would affect different minds very differently. It drove the Epicurean to consider how he might make a world in which he should live comfortably, without distracting visions of the past and future, and the dread of those powers who no longer awakened

in him any feelings of sympathy. It drove Zeno to consider whether a man may not find enough in himself to satisfy him, though what is beyond him be ever so unfriendly. This again was no new problem, either for a practical man or a theorist to deal with. Again and again it had presented itself to the Greek sages; again and again experiments had been made to solve it, and the conditions under which it could and could not be solved had been profoundly investigated. Here then, as in the former case, we can expect no originality in conception; the sole interest lies in the thorough desolation of heart which led the philosophers of the Porch to venture once more upon this inquiry. We may trace in the productions which are attributed to Zeno a very clear indication of the feeling which was at work in his mind. He undertook, for instance, among other tasks, to answer Plato's *Republic*. The truth that man is a political being, which informs and pervades that book, was one which must have been particularly harassing to his mind, and which he felt must be got rid of before he could hope to assert his doctrine of a man's solitary individual dignity. Herein he showed a degree of insight and honesty which were wanting in his successors, who were anxious, it seems, to suppress his testimony against Plato. In other respects he was also superior to them. He appears to have carried out, with some consistency and steadiness in his life, the principle for which he was contending, really showing an indifference to outward circumstances, and maintaining, with less dogmatical affectation than many others, a creditable independence and uprightness of character. Probably his system was, on this very account, less compact and formal; at all events, we find that some of his immediate disciples adopted very opposite notions of it, one at least teaching a doctrine, as to its results, not very distinguishable from the Epicurean. The person who put an end to these diversities of opinion, and established the Stoic sect, was Chrysippus. He appears to have had a full measure of that taste for system building, and skill in the work, which belonged to all Greeks, and appeared most conspicuously in those who had least of practical earnestness and sincerity. It may be worth while to trace very briefly, how the first naked conception of a man striving to live in himself, uninfluenced by the men and things around him, worked itself out into a compact and tolerably consistent theory of the universe.

It was not likely that the Stoics would invent any division of studies different from that which use had so long sanctioned, or that they would be so negligent as not to extend their theory into the different departments of Morals, Logic, and Physics. They introduced, however, a novelty of expression. They spoke of virtue as being ethical, logical, and physical. It was not that these were three different kinds of virtue, but three different parts which composed it. Logic, they said, was the shell of the egg, ethics the white, physics the yolk. Much may be learnt from this language. First we learn that virtue, a certain state of mind or character in the individual man, is all that the Stoic is capable of conceiving. This is the ultimate idea upon which all ideas of truth, as well as of outward tangible forms, are dependent. It will be seen at once how easily such an opinion as this grew out of the Aristotelian doctrine, and yet how it may have appeared, in certain points of view, more unlike to that than to the Platonic. In the doctrine of Socrates developed by his great disciple, virtue in man is always in conformity to a standard out of himself, a participation in that which is absolutely good,

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

and inseparable from the possession of that which is absolutely true. This doctrine Aristotle rejected, striving to separate practical morality into one department, and the study of Being into another. Upon his system, virtue and happiness acquired the substantive and independent character which neither Socrates nor Plato could ever have assigned them. But the very separation which he had effected between the provinces of Ethics and Ontology, enabled him the more easily to follow the natural bent of his character, and to represent the contemplative life as the highest life—that which peculiarly appertains to the philosopher. The Stoic, in carrying out his conception respecting virtue, disconnecting it entirely from every dream of an absolute good, rejected with indignation his praise of *θεωρία*, and seemed to return to the older Socratic language by representing virtue as consisting in a conflict with appearances and deceptions. But the fact is that the Stoic took only the negative side of the Socratic doctrine; his virtue had nothing to converse with, nothing to behold but itself; the impediments which it was to clear out of its way, the temptations which it was to resist, were not those which dimmed the human vision and prevented it from beholding its proper object, but only those which made it less conscious of its own independence and glory. The Stoic ethics, therefore—borrowing all which was genuine and vital in them from the language of Socrates respecting the slavery of the undisciplined and sensual spirit, borrowing also and misapplying many of his phrases respecting the connection of virtue with science—so far as they were of native manufacture, consisted merely of pithy maxims of conduct, wire-drawn and minute, entering into the lowest details and frivolities, tending to emasculate the character under pretence of elevating it, and worthy of the censure that they were fitter for nurses than for philosophers. This was the white of the egg.

That Dialectics should have been nothing more than the shell, is a proof how very little of the real feeling of the Socratic philosophy had survived in this feeble imitation of it. In fact, the language to which we have just alluded, in which science was represented as connected, nay, almost identical, with virtue, meant, in the mouths of the Stoics, nothing more than this—that a virtuous man is a man of good taste, has a shrewd discernment of what should be accepted and of what should be rejected. Truth as reality, falsehood as a positive opposite to truth, they in nowise recognised. Dialectics, therefore, in the Platonic sense, which is the science of distinguishing between this truth and falsehood, they had no use for. All they understood was that in some way or other that which is desirable is preferred by some and not preferred by others, and that it was necessary, therefore, to inquire what it is in us which determines the fitness or unfitness of things, how we know when we get a right result from things and when we get a wrong one. In all essential respects their conclusions upon this subject were the same as the Epicurean, that is to say, the one has just as little belief as the other in any standard besides sense, in any difference between the real and the apparent. The difference of their moral scheme, however, made the Stoics unwilling to acknowledge this similarity; they wished to persuade themselves—to a certain extent they could persuade themselves honestly—that those who aimed at the attainment of virtue as their end, could not have the same fluctuating rule and measure of what was good, as those who aimed only at the production of certain pleasurable results. The Stoics

sought therefore for a science, though they could not reach it; and in their attempt to reach it they invented a number of acute verbal distinctions, which, with some mixture of grammar and rhetoric, constituted their dialectical virtue, as those rules of behaviour of which we spoke just now constituted their moral. Certainly this was very fitly compared to a shell containing no nourishment in itself, and so conveniently fragile as to afford an easy passage to the yolk within.

It may surprise our readers that the essential part of the Stoical egg, the whole of which is the type of Virtue, should be the physical part. But there is nothing really inconsistent in this notion, either with the origin of Stoicism or its after-developement. If the Epicurean undervalued physics because they spoke of something fixed and preordained, something therefore inconsistent with that adjustment and adaptation to circumstances and accidents which he considered his chief good, the Stoic, who wished to rise above circumstances, to attain a firm and independent position, as naturally delighted to contemplate an undeviating system. The perception of any real law and standard for man had forsaken all alike. But there are some who can never lose their deep feeling of the necessity for such a law; these therefore, in their despair of discovering it, will take refuge in the most exact type and counterpart of that which they are seeking, in the sequence of the operations of nature. The invariable attendant upon this feeling is, reverence for fate and necessity, with a proud and voluntary submission of ourselves to its dominion. Such a Fate became the god of the Stoic, strictly speaking his only god; but as he saw it imaged in the movements of the universe, and as he felt at times the need of something more real, more connected with himself than this abstraction, the World became the living form in which he contemplated the object of his worship. And since he found it expedient for strengthening some of his moral habits, and accordant with some of the maxims of his philosophy, not to reject old opinions, he easily persuaded himself to adopt the opinion of Aristotle, that the old legends did in fact represent processes in the material world. They might, therefore, without any violation of his philosophical dignity, be recognised and defended. Theology being thus identified with physics, it surely becomes no matter of surprise that the latter should be treated as the most inward and sacred part of morality.

One sect yet remains to be mentioned before we can complete our picture of Grecian philosophy in its decre-
The Aca-
demics.
pitude and decline. We have seen how entirely the very power of conceiving that which we have described as the central principle of Plato's philosophy had departed from his countrymen. All his language about Being was to them the merest dream; they could not even understand the elaborate arguments of Aristotle against his doctrine, nay, his own views respecting the Form and the Matter in each substance had become practically as unintelligible as the deeper speculations of his master. Under such circumstances we may easily conceive what a change must have taken place in the schools bearing their names. The Peripatetic, who worshipped the name of Aristotle, might still satisfactorily expound his Physics, his Logic, part of his Metaphysics, and whatever of his Ethics could be detached from the Politics; but the Academics found the incomprehensible part of their master's creed impregnating all his works; it could no more be detached from the *Phædrus* and the *Phædon* than from the *Republic*. There was, however, one circumstance in

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphy-
sical Phi-
losophy.

their favour. For reasons which we have considered at quite sufficient length, the great principle of Plato is developed in dialogues, in which two propositions seem to be set up for the purpose of knocking each other down. Could any thing be more natural than the notion that Plato intended hereby to keep men's judgments in a perpetual equilibrium, to maintain, in short, a habit of entire interminable scepticism? The conclusion was most plausible; yet so much did there appear in the writings and in the whole purpose of Plato to refute it, so much did it seem the very object of his life to overthrow scepticism, that a long time elapsed before this plausible notion was able to establish itself. The Academy appears to have undergone many changes; what they were has been the subject of much controversy, but the language of Cicero leaves little doubt that it did at one time assert certain dogmatical propositions as the doctrine of Plato, and that it passed by slow degrees into that purely sceptical society from which he derived, or fancied he derived, his own opinions. The result is curious, but by no means inexplicable. Scepticism was, as we have said, the foundation of both the other sects, though they attempted to break loose from it. The Academy yielded submissively to the spirit of the times, and embodied it most consistently in his own *no views*. He discoursed eloquently upon all topics, carefully abstained from coming to a conclusion upon any; he could not say what was right, but he was satisfied that both Epicurean and Stoic were wrong, and this was quite sufficient for his purpose. Arguing was his vocation, a kind of arguing, however, which did not exclude an indulgence in all flights and flourishes of rhetoric, when the occasion might serve for their introduction. In fact, the disciples of that philosopher who wrote the *Gorgias* and the *Phædrus* became nothing else than the teachers of wiser and better men than themselves how to be Sophists and Rhetoricians. Such were the lees of Greek philosophy, from which one may conjecture in some degree how rich must have been its flavour, how full its body, when it was in its prime.

Roman Period.

If the view which we have taken of this last period be true, the trite saying that Rome conquered Greece with arms, and Greece Rome with wisdom, must be understood in a very modified sense. We do not mean that too much has been said of the effects which were produced upon the Roman mind and character by the Athenian teachers who came to Rome, or by those to whom they resorted in the schools of Athens. Undoubtedly the discovery of a new continent, which could be actually trodden with human footsteps and seen with human eyes, may have produced less wonder in the mind of a Spaniard in the XVth Century, than the apparition of the invisible world, which the Greek sages spoke of, upon the countrymen of Camillus and Regulus. The doubt we wish to express is, whether the Romans were merely conquerors with the sword, and whether they ever succumbed passively to the philosophy; whether they did not leave upon the thoughts and doctrines which they seemed to imbibe so simply and devoutly the impression of that character which several ages had been contributing to form. This question can only be answered by considering very shortly the remains of Roman philosophy, and the hints they supply respecting the state of feeling in the nation which produced it.

The poem of Lucretius naturally presents itself as the first and most marvellous outburst of that spirit which all the wisdom of the Censor and of the older Romans was unable to keep in check. Every thing at first sight tends to heighten the wonder which this poem produces in us. All the philosophical poems of that nation which had furnished the language of philosophy, and given birth to the most splendid poetry, have perished; only a few fragments remain of the verses in which Xenophanes and Parmenides conveyed their opinions; Empedocles of Agrigentum is but the shadow of a name. Nor have we any reason to believe that the productions of these men, though they were to all appearance men of genius and originality, deserve to be regretted, at least as works of art. How very strange, then, does it seem that the greatest effort of Roman genius should be a work written on a subject utterly alien from the habits of the Latin mind, by a young man struggling with a language which, for his purposes at least, was barren and uncouth; a language too which one would have thought could only have become poetical when it was used to speak of the actions of great men, and of people subdued to laws. It may seem to some even a more astonishing circumstance than any of these, that the theory which Lucretius undertook to defend and illustrate was, of all that Greece had produced from the days of Thales downwards, the hardest and most mechanical, one would have said the most flat and prosaic. It would be an easy and flattering way of meeting these thoughts which will naturally occur to any one who is reading the poem, to say that genius is only called forth by difficulties, and that if it had nothing to overcome it would not deserve its name. No doubt this is true, but still there is a fitness in the choice of subjects which we are generally able to recognise, and without which it is hardly possible that a work, even if it were written, could become a great national possession. With respect to the doctrine no thoughtful reader can believe that it was adopted, from a false notion either that it was particularly suited for poetry, or that great fame would be obtained by triumphing over its unsuitableness. Lucretius writes with the most entire conviction; his whole mind is evidently impregnated with his doctrine. And this was one necessary condition of his producing so great a poem; he felt what he said; a feeling of earnestness, which had not been in the mind of any Greek for at least two centuries, had got possession of his. He may have selected a miserable idol, but such as it was he rendered to it the most entire devoted worship. Now this earnestness he owed to his Roman education. The distinct aims and purposes of the Roman citizen, the active living world in which he dwelt, the feeling of order in all the movements of the society to which he belonged, presented the strongest contrast imaginable to the state of those who delighted in nothing else but either to tell or hear some new thing. At the same time, to a young Roman, who had contracted unconsciously this sense of order and reality, and who had been trained to contemplate the heroic models in the early history or the traditions of his country, who had not perhaps himself any strong impulses towards active life, or much of the legal and rhetorical abilities which were the qualification for it, the rage and contention of parties, the atrocities and the meannesses which, in the days of Marius, Cinna, and Sylla, he must have heard of every day, will have been most distracting. We may be able to perceive how much better the state of

Moral and
Metaphy-
sical Phi-
losophy.

Lucretius.

Moral and
Metaphy-
sical Phi-
losophy.

society in that age, with all its abominable crimes, was, than the dreary condition of Greece, even when its sleep was confused by those dreamy efforts of patriotism which the appearance of Flaminius and the Romans called forth. We may see that great social principles were struggling with each other in those conflicts of rival parties which could not have left such an impression upon history, if there had not been much good mixed with the apparently unbroken evil. But to a person of the time, such as we have supposed Lucretius to be, the misery and confusion will have presented themselves almost without relief; and then, little knowing how much he was indebted to the forms of his country's polity, and to the truths which lay underneath its false worship, for the disgust which such spectacles excited in him, he will easily have been led to question the worth of that faith and reverence by which a system of falsehood and cruelty seemed to be upheld. In such inquiries, he will probably have found most of the thoughtful youths about him engaged, with no great difference in the result, except that they could abide quietly in contempt of the popular opinions, while he required some positive substitute for them. Arriving with such feelings at Athens, what could be more natural than that the words of the clever Epicurean lecturer should take a hold of his soul which they never had obtained over the person who uttered them; that he should have welcomed them as the deliverance from an intolerable burden, as the discovery of a region of which he had been dreaming, but which he never believed to exist; nay, as the satisfaction of that love of order which his Roman discipline had imparted to him, and which the circumstances of Rome itself were continually affronting. A poem on the Nature of Things, written under such circumstances by a man possessing the vision and the faculty divine, might well embody some of the deepest, strongest, nay, truest feelings. The strongest patriotism, the greatest command of his native tongue, might be exhibited by a man apparently adopting all the habits and notions of a Greek. Under the guise of Epicurism, he might express a religious desire for a deliverance from the tyranny of powers whom he could not love; the Democritic concourse of atoms might convey to him his first real notion of any scheme or order in the universe: and such a poem might well become national, for it would express the very state of mind of the age in which it was produced as reflected in the person of the most genius; it would bring out the whole nature of the union which was effected in that age between Greek speculation and Roman life, and would show how the latter really asserted its dominion over the beggarly materials with which it had to work.

We have no excuse for dwelling at any length upon this noble poem, both because it is so well known, and because the illustration which it gives of Roman feeling at this crisis is the chief light which it throws upon the history of philosophy. In reference to that point, however, we would direct the attention of the reader to one circumstance. Epicurus, as we have seen, valued himself mainly upon the moral or human part of his system; the physical, which he borrowed from Democritus, was adopted only as a resource. Lucretius, on the contrary, at once fixed upon the atomic theory as the central part of his philosophy. Nothing can illustrate more strikingly the difference between him and his master. How to find an excuse for a voluptuous indolent temper, whether it were a sensual one or not; how

to arrange the world in conformity with it was the problem proposed to himself by the one; to recognise some kind of principle and connexion in things was the delight of the other; which, being their respective impulses, we may fairly say, that Lucretius differed more in spirit from Epicurus than either Zeno or Chrysippus did.

But these also were to have their disciples among the noble youth of Rome. The transformation which took place in the dry chips of doctrine which were delivered in such solemnity in the porch, when they were taken into such hands, was marvellous. If there were some of a more adventurous genius, who fled *ex fœce Romuli* to the study of the laws of the material universe, there were many more who found their great relief in contemplating the severe forms of the elder Romans, who either saw in the records of their country, or created out of the materials which they furnished, men of a stately character to whom wealth was indifferent, who loved their country above all things, and could sacrifice themselves, or whatever was dearest to them, for its sake. Between such simple men and the stiff solemn conscious Stoic a whole heaven would seem to intervene. Yet there was enough of external resemblance in the two characters to deceive those who felt that they wanted some knowledge which their fathers had not, who were unwillingly half ashamed of their old ignorance, and half afraid of their new philosophy, lest it should weaken their admiration and their patriotism. To be taught how they might upon rule and principle be that which their ancestors had been from some high and unattainable instinct, to be taught how they might be only better and more consistent Romans for this Greek infusion was most soothing and satisfactory.

That such feelings existed we have abundant evidence, but they did not, like the thoughts of the great Epicurean, find their principal expression in words. The lives of Cato and Brutus—the one more formal and severe, as of a person who felt that he was trying to support a character, the other more genial and free, like one who had really caught the spirit of the olden time,—both Roman aristocrats at heart, however they might speak the language of the schools—these are the true utterances of Roman stoicism, which have thrown a splendour around the doctrine that it could never have obtained either from its first teachers or from Seneca and the rhetoricians who afterwards talked of it in Latin.

Thus far we have seen the Romans only translating Cicero. into living words or living acts the dead formulas of the Greek schools. But Rome was also to have a formal philosophy of its own, and if not to make any new discoveries or to follow any course of thought which had not been previously marked out, at least to fulfil a useful office by giving a dignity to one particular department of thought, which, in the minds of even the greatest Greeks, had obtained only a secondary importance. We have spoken of Cicero as an Academic; and doubtless there was much in his character, in his political career, and in his rhetorical habits, which might have led us to predict that this was the sect to which he would be most naturally drawn. He appears to have had a singularly equitable, balancing, compromising nature. The circumstances of his age, the utter impossibility of adhering with steadiness to any one party, when parties were so constantly shifting their ground; his conscientious unwillingness not to take some part in political life, or to set up any immutable, unattainable standard for those who were engaged in it, confirmed all

sical Phi-
losophy.

The Ro-
man Stoics.

Moral and
Metaphy-
sical Phi-
losophy.

his original tendencies, and the profession of an advocate riveted and perfected them. Though certainly not the person to be fixed upon as exemplifying the highest form of the Roman character, he had in a remarkable degree the Roman temperament, and he seems especially formed to show us what the intellect of his nation was when at its greatest natural stretch, not raised by some extraordinary impulse of genius or devotion above itself. On this account it is that his letters, speeches, and dialogues present so perfect an image of his own age, and that some have thought a history of Rome might have been composed from them, if all other monuments were lost. But it must be observed, that merely practical wisdom is not able to express and embody itself in words till it has been mixed with an apparently incongruous element. If Cicero had not studied Greek philosophy, and been, so far as a most accomplished scholar and statesman can be so, a pedant, he would not have enabled us to understand himself or his countrymen as he has done. His philosophy was unquestionably important to him and to us; still it is amusing to hear him speak as if his habits of mind had been in any considerable degree moulded by its influence, when it is most evident that they were wrought into him by the influence of old forms and institutions, by the circumstances of his country, and the tone of the men who surrounded him. These contributed to the system of philosophy which he took under his patronage, far more than they received from it. He found the Academics treating philosophical questions in the same manner and with the same fairness as prosecutor and defendant were treated in the Roman courts, arriving at no settlement, as he could arrive at none in the disputes of factions, yet inclining to established notions in opposition to the dogmatical denials of the Epicurean, and to a moderate behaviour accommodated to circumstances, in opposition to the fixed rule of the Stoic, and he was irresistibly prepossessed in favour of their views. But that which gave those views favour in the mind of the Greek was their fitness for talk, a talk which might be carried on for ever without the least reference to life. That which endeared them to the Roman was their apparent suitableness for practice, their seeming to show the very point where the lines of philosophy and practice intersect each other. This was the point at which he was aiming; and in his own speculations, however they may seem merely derived from the Academics, he is continually bringing it before us. If there was one feeling in which the Greek academician was utterly deficient, it was the feeling of Duty, the feeling that there is a work which a man is sent into the world to do. This feeling is wanting in all the sects; each was framing a scheme of life, or aiming at some ideal of excellence; none was acknowledging a vocation. It would be very unjust to say that the sense of duty was absent from the minds of Plato and Aristotle; they had it unquestionably, or they would not have been what they were, or have done what they did. But it is true that it was not the prominent characteristic in either of them, or in any Greek. On the other hand, this feeling is the one which gives all the meaning and interest to the works of Cicero. You can always see that he is impatient of any subject which he does not think has a direct bearing upon human life; that when he writes upon such subjects, he has only the use of his left hand; that they never do really affect him at all; that he has no opinions upon them and does not care

to have any. He will therefore retail the opinions of all the philosophers so far as he knows them, or will allow some able representative of the different sects to state the views of each, and will seem to have no aversion to any thing but the dogmatism which each exhibits. Yet in the end you find that he has a set of firm convictions in his mind, which have remained undisturbed by all these controversies, and by his own nominal scepticism. He can see nothing but a difference of words between the Peripatetics and the Academics, and it is quite clear that he means to extend the observation to the original masters of those two schools. The whole subject of Being and of Ideas, about which Greek philosophy in its best days was wholly conversant, is an unknown world to him. Plato he looks upon chiefly as the most eloquent of men; from Aristotle he has gained good helps in the study of rhetoric. One cannot discover that he cared any thing about Physics; Logic he prized chiefly as a mental exercise, and in all disputes about the Nature of the Gods, so far as they bear upon either of these subjects, he seems to be neutral, and, if one tried him by modern rules, we might fancy, atheistic. But he is not so at all; he has a much stronger belief in a divine power, and a divine government, than many whose opportunities of knowledge are infinitely greater than his. But he attained this belief without any assistance from the Greeks, and he retained it not at all strengthened certainly, but not materially weakened by what he learnt through them. Without a Divine Being there can be no sanctity, no duties, no laws; this was the conclusion of his heart and reason both, and he felt that it was a deeper and securer one than any which arguments could furnish him with. This ground, therefore, he vindicated to himself; he brought out the idea of MORAL OBLIGATION with a distinctness with which it had not been presented before. Not that it would be easy to point out passages in his books in which the subject is discussed amply and satisfactorily; not that the student will not often have to complain of much looseness in his language upon it; not that he will not be sometimes puzzled to conceive how so much indifference to absolute truth can consist with a strong sense of moral duty: yet this seems to be the total effect of his books—the result which is left upon our minds both by their merits and their omissions. Though he has established nothing, he leaves us with the conviction that something is established, and that it is not something independent of us, but something with which we are concerned, and in conformity with which we are bound to act. His philosophical works, therefore, appear to have been unjustly exalted, and as unjustly disparaged. When he is used as an interpreter of the elder Greeks, when we try to understand Plato through his means, we confer on him a station which was never intended for him, and he will unquestionably lead us astray. On the contrary, when we regard him merely as the translator into eloquent Latin of what he had heard from his teachers in Athens, we degrade him just as unfairly. His philosophy has a substantive value; such language as his can never be a mere clothing for other men's conceptions, though it may not be a fitting expression for the very deepest ideas. And it should be observed, that in those works wherein he has adopted Plato's titles, and might seem to have followed him most closely, as in the *Laws* and the *Republic*, he has really drawn most upon his native resources, and established the truth of his own words, that he had learnt more

Moral and
Metaphy-
sical Phi-
losophy.

Moral and Metaphysical Philosophy. Moral and from the Twelve Tables, than from all the philosophers. This seems all that it is necessary to say in so brief a sketch as ours of Roman philosophy; for in the poem of Lucretius, the biographies of the last champions of the republic, and the conversations of Cicero, we have it in its purest form. It imparts richness and refinement to the *Georgics* of Virgil and the *Epistles* of Horace, and adds solemnity to the dirge which Tacitus sings over his fallen country. But the character which it assumed in these really remarkable men, as well as in those who adopted it merely as an excuse for uttering fine sentences, will be easily understood, if we form a right judgment of its earlier appearances. We pass on, therefore, to the last conspicuous form of ancient philosophy, which is the one that it assumed at Alexandria.

Alexandrian Period.

Under this head we do not propose to speak of the different Greek philosophers who may have settled in Egypt during the reigns of the Ptolemies, and have carried on the different physical, moral, and philological inquiries which had been suggested by the founders of their respective schools in Greece. These in themselves constitute no era in human thought; they are only important as parts of a stream which it would be very interesting, if it were possible, to trace, with all the different accessions that it received from various directions, till the time of its confluence with another from Palestine. No doubt the habits of the Greek mind underwent some modification after such a new and strange book as the Septuagint translation appeared among them, and so marvellous a people as the Jews began to hold familiar intercourse with them. But it is very difficult to ascertain what that modification was; very likely it was more striking in the humbler classes than in the philosophers. Their minds were well prepared to resist anything living, original, and true, even if it had not claimed the authority of a revelation. But the effect produced on the other party was very different. How far it is to be discovered in any of those books which form what we call the Apocrypha, we can do no more than conjecture, especially as the dates of those books are so uncertain. At all events it is so visible, and so generally recognised, in the writings of some who lived at the close of the Jewish age, that we need not waste our time in searching for earlier and more doubtful indications of it.

Josephus. It is hardly necessary to speak of the writings of Josephus as affording an instance of an attempt to combine Pagan with Hebrew notions. The experiment in his case is conducted so awkwardly, his philosophy was such an inconvenient addition to his better qualities, it evidently had so little other influence on his mind than the disastrous one of spoiling his simplicity and unfitting him to understand the records of his own land, that his case is interesting in this point of view, chiefly as indicating a prevailing habit of mind, and perhaps as exhibiting a form of it which we do not meet with elsewhere, that, namely, which resulted from the interweaving of Roman rather than Greek feelings with those he had derived from his birth. Philo is altogether a different person. In opening his works this observation at once suggests itself to us. Here is a man living in the age of Cicero, and possessing a mind certainly not naturally so large or rich as his to whom a whole world of thoughts have discovered themselves, of which the Roman's writings contain no intimation. And

what is more remarkable still, those parts of Plato's works which were to the cultivated and accomplished Roman mere blanks, are to this Jew full of life and meaning. His position in Alexandria was not more favourable for this purpose than was that of Cicero. The latter had all the advantage he could derive from the best and ablest teachers of Athens, the language of Plato presented no real obstacles to him, and if the schoolmen of Greece had become a set of shrivelled rhetoricians, there is reason to believe that the schoolmen of Grecian Egypt were not less so. All Philo's intuitions respecting the meaning of those deeper passages in Plato's writings which speak of absolute being, and of an idea or essential form, through which that being declares itself, he must have owed to some other help than any which he derived from his native genius or his accidental position.

We would have the student consider this fact seriously and steadily, for it will help him much in estimating the value of Philo's writings in themselves, and the kind of lesson which we are to derive from them. A certain degree of discredit attaches to his name as an allegorist and a mystic. At the same time his writings did exercise a great and remarkable influence over the first ages of the church, and no one, we are certain, can contemplate them with reference to the history of philosophy, without perceiving that they must have had this influence, and that it was not the effect of any spurious reputation for sanctity in the author, or of any accidental circumstances whatever. At the same time we admit fully that no person of simple, honest mind, whether he reverences the Hebrew Scriptures or not, can rise from the perusal of some treatises of Philo's, in which he tries to deduce different Gentile discoveries out of them, and to turn plain history into divine speculations, without a sense of annoyance and perhaps indignation. We feel there is something in it not honest and true; an impression strongly confirmed by the style, which is of that kind which may be called painfully expressive, every word being charged with some elaborate meaning, and there being, in even very elaborate and eloquent passages, a consciousness of eloquence which is most distressing, and which places Philo at a marvellous distance not merely from the prophets of his own race, but from those heathens who were the objects of his study and admiration. And yet if we are honest with ourselves, this conscientious displeasure will not hinder us from acknowledging that he has brought forth not merely great ideas but practical truths of the greatest moment to our lives, and that he has, in some way or other, imparted the conviction to us that these truths were contained in the scriptural narratives and stories from which he deduces them. These two impressions may seem very contradictory, but let the reader consider faithfully with himself whether they are not both made upon his mind, and if he finds it to be so, let him pause before he hastily or impatiently seeks to efface either. A little reflection may perhaps enable him to find that both ought to be retained, and that they may be reconciled.

One conclusion has been forced upon us by all our observations of moral and metaphysical inquiries hitherto. We have seen that in Greece they could not take their rise, where men had no sense of a government or social position; that the fact of that position was one which haunted the minds of those who seemed to be pursuing their inquiries in the most opposite direction, and greatly modified the character of them; that when these

Moral and Metaphysical Philosophy.

Moral and
Metaphy-
sical Phi-
losophy.

inquiries were in their strongest and healthiest state, this fact became the centre towards which they all converged, that when the sense of it was lost the inquiries became feeble, narrow, unreal. This moral we have been obliged to repeat even to weariness, so directly does it result from every fresh portion of the evidence, and not least from that comparison of Greek inquiries with their supposed Roman copies, into which we have just been entering. Connected with this conclusion was another, that all brave and adventurous inquirers respecting those things which lie beyond the ken of our senses had received their encouragement and hope from traditions of men who had actually been favoured with communications from that invisible world. All the most thoughtful philosophers we have seen rather endured the puzzles and confusions of their traditions than parted with the faith which they conveyed to them, and never in their sober moments believed that the discoveries or intuitions of their minds could be a substitute for actual revelations, though they might constitute a capacity for receiving them. The loss of a clear conviction on this point in Aristotle was accompanied, we noticed, with the loss of a belief in absolute truth, at least as necessary for mankind. Still the belief lingered in his mind, that the contemplation of this truth was the very highest attainment of the philosopher. The next stage presented us with the loss of this feeling altogether, with an utter unbelief in all traditions, and also with a practical disbelief of any thing but that which the senses could measure. Which disbelief we found had no real place in the heart of a poet nominally Epicurean, because he was still, however unconsciously, possessed by the old habits and convictions of his country. All these discoveries would seem to favour the opinion which we took for granted at first, because it is the opinion which we all profess, that one nation did receive an actual communication from heaven, had an actual polity divinely contrived for the purpose of educating it into the truths which were contained in that communication, and that hence had arisen all the earliest and deepest searchings of the human spirit concerning itself and Him from whom it is derived. It would seem also to favour the opinion, which we also assumed, that at a certain period in the history of the world, after these inquiries under the direct influence of a divine revelation had reached a certain point, it was a part of the divine scheme that another set of inquiries, conducted without that influence, but not without the feeling of its necessity, or the recognition of a divine presence conveyed through many broken, obscure, and degenerating traditions, should have been carried on in some other country, specially prepared by the character of its people and the nature of its institutions for this purpose. Nor is it easy, as we observed, to avoid the belief that at some time or other these two schemes would find a point of coincidence. Yet that actual revelation should be made unnecessary by human discovery, or human inquiries be stifled by a divine revelation, is impossible, unless the history of both were falsified, for each had been manifestly demanding the other. The difficulty must have presented itself strongly to the mind of any man living in Philo's position; it must have been augmented greatly by the observation that for a long time there seemed to have been a dearth, as much of any powerful intuitions in the minds of men, as of any direct communications from above. The thought was surely not an unnatural one, that the former required to be

rekindled by light borrowed from the latter; that, on the other hand, the cold and dreary acknowledgment of a set of strange miraculous facts, might acquire an altogether new life if they were shown to be connected with thoughts and feelings which had deservedly won for men the reputation of sages. It is not necessary, surely, to conceive that any false spirit of accommodation, or any scepticism respecting the actual events which seemed instinct with so much meaning, moved him to this enterprise. It was one to which a man of an earnest, meditative spirit, living in such a time and in such circumstances, may have felt himself prompted by a very sacred impulse, and one which could hardly fail to produce some results most beneficial to mankind.

Accordingly we believe it was given to Philo to bring out into clearness, by help of the Jewish Scriptures, some principles of the Platonic philosophy which Plato himself could but partially apprehend. That which was a wish in Plato's mind—a wish and a kind of moral necessity—to connect the absolute being, the *to ov*, with personality, was involved in the very principles of the Jew's mind. If he ever used other language, as indeed he did too often, it was a wilful abandonment of his privilege, if not for the sake of pleasing Gentile ears, in the honest hope of making his countrymen less slaves to particular phrases by occasionally departing from them. It was given to Philo, in strict accordance with this difference, to connect the aspirations after wisdom in heathen men with those mysterious utterances respecting the Wisdom whose delight was with the sons of men, and the Word who spoke to the hearts of the prophets, and thus to establish the truth for which Plato was all his life contending, that the idea which the wise man beholds and tries to reach, is not a shadow cast from his own mind, but a substantial reality, existing distinct from himself, in which he is constituted. It was given to Plato, lastly, to show how those forms of virtue and loveliness, which Plato believed that the soul is meant to contemplate, are actually connected with that one fontal source of all loveliness, and have been exhibited to his creatures in various human models, who confessedly drew their light and life from him. In this way Philo may sometimes find a meaning for the word philosophy, which throws a light back upon all past Greek speculations.

But how then do we account for that want of simplicity which we spoke of just now? and on what ground do we affirm that with all his advantages he was a less true man, and therefore a less safe guide, than his Grecian master? The apparent contradiction may be explained in this way; Plato, we have seen, in all his loftiest discourses respecting the dignity of the philosopher, his distinction from the sensual herd, his right to govern them, never loses altogether sight of the truth that the philosopher is not of another race from his fellow-creatures, but only the one who is seeking to realize the humanity which belongs to all, that he is less exclusive, less self-seeking, less self-glorifying than others, that he values himself less upon particular gifts and properties, and seeks more after a common and universal life. We do not say that there are not many passages inconsistent with this feeling; we admit that it was the hardest thought for him to realize, and that he never did realize it thoroughly. Still the conviction lay very deep in his mind, and the *Republic*, rightly and simply interpreted, is throughout an endeavour, amidst great perplexities and contradictions, to express it.

losophy.

Now this feeling ought surely to have been far more present to the mind of Philo. Every thing in the records which had been familiar to him from his childhood, should have taught him that his privilege was to belong to a race. Every member of that race was dear to Him who had entered into a covenant with it. The highest models of virtue held up to the imitation of Jews were not men who had thought great things of themselves, had proposed to themselves the attainment of some splendid character, had been chary of their reputations, but men who had identified themselves with their countrymen, had felt their sorrows and sins as their own, had wished for no better destiny than theirs; had not cared to be thought ambitious, rebellious, impious; had toiled on, in simple faith, entire dependence, and great suffering; thinking nothing of themselves, or if thinking, thinking only shame, desirous only to magnify that light which was shining and making itself manifest in them and through them. Of this Philo seems to have had but very indistinct glimpses. He himself is a conscious philosopher, striving consciously after a perfect form of character, and what he is, he imagines his brave and single-minded countrymen to have been; not plain simple herdsmen and warriors, serving God, and content to do any work he may set them upon; but men with the object constantly before them of making themselves heroes and saints. We do not mean that there may not be splendid passages in which he speaks of men living for others and not for themselves; but all this belongs to an ideal of character. It helps to make up the fine holy man and great philosopher. Hence results, we believe, that feeling of displeasure, and even disgust, with which honest minds turn away from Philo's commentaries upon the characters of the Old Testament. For this is the real cause of his disposition to allegorize. He cannot endure any thing so vulgar as sheep and oxen, as men fighting battles with actual swords and spears. He cannot see a meaning in these things, and therefore he must find a meaning for them. He cannot see God working in the actual affairs of earth, and therefore instead of seeing any thing as it is glorified and translated into the signification of something higher, he must separate essences from forms, till the first become vapours and the second husks. It is quite true that he did not act upon this notion in respect to the forms of his country's worship; those he prized, as containing the essence, as being some of the great means for cultivating the mind of the theosophist to the perfection for which it was destined. But while he was taking away the sense and feeling of reality from the things with which our senses converse, he was in fact destroying the principle of these forms; at all events limiting the mystery of them to sages, and undermining the great doctrine which they were proclaiming, that the highest life, the deepest truths, are the inheritance of men who live by the sweat of their brow.

Nothing could have been such a shock to the disciples of the Alexandrian school, as the announcement that a peasant of Galilee was He whom, in so many mysterious passages of their nation's records, they had been tracing as the source and spring of all the light which had been in the hearts of faithful men in the chosen nation, or even which had diffused itself through the world. Probably, not the proudest pharisaical ritualist, or the coldest moralist among the Sadducees, would have been so shocked at such a proclamation. For on the first of these, as he studied with

hard literal accuracy the Scriptural records, the thought may now and then have dawned that, as every past prophet or king, in whom any portion of the divine glory had revealed itself, had been cast low that he might be exalted high, this, in some great and transcendent way, should be the condition of him in whom it was to reveal itself perfectly. To the Sadducee, whether he studied in the Epicurean or Stoic school, (and probably there may have been some in that sect who had studied in each, the negative characteristic of indifference to the higher hopes of their countrymen, and not any particular positive opinions, being the symbol of their union,) it may now and then have occurred that no more perfect type of that moral quietness, which adapts itself to all circumstances, or of that moral grandeur, which rises above all, had ever presented itself to them in any records than that which they then saw before their eyes. However unable such thoughts may have been to break through the religious pride of the one, or the intellectual pride of the other, they may, one would think, have come to each occasionally. But the Alexandrian, conscious of the profoundest reverence for Scripture and philosophy, regarding the mere literalist and the mere moralist with equal contempt, but abhorring most of all every thing which vulgarized high truths, and brought them into contact with the hearts of simple men, will hardly have ventured to ask himself, even for a moment, whether any one Old Testament vision, whether any one Platonic aspiration, could have had its fulfilment unless the absolute Being revealed himself to his creatures in the likeness of a man; unless the perfect Idea of truth and goodness proved itself to be substantial and not imaginary; unless he showed that he could both exhibit himself to men, and abide in them; unless the Word could take flesh and dwell among men; unless, in their nature, he could overcome all moral evil, and turn physical evil from a curse into a blessing; unless he could establish that perfect commonwealth, of which Plato said, that the type of it was, perhaps, in the heavens, and which he hoped would one day be set up on earth. Through another entrance than that of Alexandrian wisdom, this faith was to find its way into the hearts of men, because it was emphatically a faith for men, and not for those who sought to separate themselves from men. In spite of that wisdom, and of all other powers and influences, it did establish itself in the world. The Christian church has become a fact which may be reasoned about as we will, but which remains a fact still. Whoso overlooks it in a record of philosophical inquiries, proclaims thereby that they have no connection with humanity; obliges himself to treat the deepest and most earnest speculations of men in the ancient world as dreams of which there is no interpretation, and leaves himself without a clue with which to trace the progress of thought in modern Europe.

PART II.

THE POST-CHRISTIAN PERIOD.

Although the space which lies before us seems far more extensive than that over which we have yet travelled, the greater part of the task which we proposed to ourselves at the commencement of this article is now accomplished. By taking up ethical and metaphysical inquiries at the point from which, as we believe, they started, not in some recent period in which they are

Moral and
Metaphy-
sical Phi-
losophy.

Moral and
Metaphysical
Philosophy.

combined with all our own circumstances and habits, we have thought that we should be best able to make our reader understand what they are in themselves, and how they become connected with each other. We seem to have learnt from the history of the Jew that there are three stages in moral inquiries. The mystery of human relationships is the first subject of them; the mystery of positive law the second; the mystery of an order, grounded upon the character of an absolute being, the last. Now as we assumed the common faith of our countrymen respecting the divine and peculiar discipline of the Jew to be true at the beginning of our sketch, we shall assume the same common faith to be true, that this education was prolonged and carried on in the Christian church. In one case as much as the other we are confident that that assumption will be confirmed by the evidence of facts, and by the clear light which it throws upon the order and sequence of human speculations. Still we use it, for the present, as an hypothesis. In consistency with it, we believe the moral education of the modern world to begin where the Jewish education ended. We believe the Christian church to start from that idea of an absolute morality which was the final point to which the Jew was brought. We believe that the work of the first Christian age was especially to lay the foundation of society and of thought upon this deep, *Absolute* ground; that the object of the second Christian age was to raise on this foundation the edifice of *Positive* morality; that the work of the third age was to connect *Relative* morality with both of these. But we look upon the education of the Christian church as not merely, though primarily, the prolongation of the Jewish development. It should comprehend, also, if our view be a right one, that series of thoughts which we have seen occupying the mind of the Greek. Those thoughts (to which we found that the name of metaphysical was especially appropriate) turn upon these three great subjects—*Power, Being, Unity*. We have ascertained already that these have a close and inevitable connection with those other three of which we just spoke; that absolute morality connects itself with that question respecting unity, which may be said to be the central one in the Greek mind; that Law, in its largest signification, cannot be separated from the question respecting Being; that there is a certain link, as real, perhaps, though not so apparent, between that inquiry into the nature of our own Powers, which is the starting point of metaphysical investigation, and that meditation upon Relationships, which is the starting point of moral inquiries. We might therefore expect that the age which was most occupied with any one of these moral subjects would be also most occupied with the corresponding metaphysical one. In the remarks which we have yet to make, we shall devote ourselves entirely to the exposition and illustration of these statements. Our object will be simply to bring out the character of different periods. Persons and systems we shall allude to only as they may seem necessary for this end, or as they mark the commencement or termination of some era. We shall endeavour to set our hints as briefly and directly before the student as possible, because their worth, if they are worth any thing, must be proved by all his subsequent reading; to assist him in that reading, not to supply him with a substitute for it, being the object at which we have aimed throughout.

As we have spoken of three periods of human thought

in later history, we shall, of course, be required to define them with some accuracy. Fortunately, our division is one that is most uniformly recognised by the writers of general history: our first period extending from the coming of Christ, or rather from the reign of Vespasian to the reign of Charlemagne; the second, from that reign to the Reformation; the third, from the Reformation to the French Revolution. That since that time we have entered upon a new period will not, perhaps, be very strongly disputed, though, wherein consists its difference from that which preceded it, and what is its particular vocation, we may be better able to consider hereafter.

From the Coming of Christ to the Reign of Charlemagne.

It has been the fashion in some recent histories of philosophy to describe this period as one marked by the concurrence of Greek with Oriental ideas. That there is a truth in this language few will be inclined to deny; we especially should be contradicting all our previous remarks if we did not recognise it; but we must contend at the same time that it is vague language, and that it is often so used as to produce the greatest confusion and misapprehension. In some cases, learned and cautious authors have been betrayed by it into what seem, to plain persons, the most incredible hallucinations. Ritter, for instance, whose historical sagacity and research are indisputable, has made a digest of Indian speculations from the writings of Colebrook and other modern English Orientalists, for the avowed purpose of assisting us in understanding the education of Philo the Jew, and so in arriving at some general notion of the elements which entered into the philosophy of the age immediately succeeding his. Now seeing that Philo may have alluded, perhaps in about half-a-dozen passages of his writings, to the Gymnosophists of India, and that there is scarcely one of those writings which does not treat laboriously of the patriarchs, law-givers, and prophets of Judea; seeing that he attributes all his own trains of thought either to these or to those who wrote in his adopted language; seeing that the education of a Jew is one of the most marked and peculiar which it is possible to imagine, and the most unlike, in nearly all respects, to the education of a Hindoo; seeing, lastly, that Ritter furnishes us with no proofs whatever that the particular systems which he describes were the Hindoo systems of Philo's day, or that if they were he had the slightest acquaintance with them, it would be difficult to point out a more striking instance of an attempt to illustrate what is near and plain by what is distant and obscure. But we may derive some advantage from this extravagance. Ritter admits that the union of Oriental and Greek ideas, which he discovers in Philo, is the same in kind with that which is to be found in the writings of Christians and Pagans in the subsequent age. If, then, we feel at once that the phrase Oriental is affected and delusive as applied to the one, we shall be at least very cautious in using it when we are speaking of the other. At all events we shall be compelled to admit, on the plainest evidence, that the influence which proceeded from the ideas of which the Jew Oriental was the depository, were altogether different from those which can have been produced by the Persian or Indian Oriental. We shall admit that the effects of the former can be traced much

Moral and
Metaphysical
Philosophy.

Moral and
Metaphy-
sical Phi-
losophy.

more visibly and clearly than those of the latter; and when we do find indications of both powers being at work, we shall believe that they were acting in very different directions towards most different ends.

It will be obvious from our last remark that we do not intend to deny the operation of certain Oriental ideas which were in no sense Jewish, upon the mind of this age; the proofs of that operation are we think irresistible, though their extent and importance may have been overrated. Neither do we deny that there is a point of resemblance between all systems of thought proceeding from the East, which does not exist between any of these systems and those which had their birth in Europe. Although the Greek speculations presumed a revelation, they never pretended to possess one; the Hindoo philosophers, even when they depart from the maxims of their sacred books, still acknowledge the existence of them. Even Greek *mythology* is mainly an ascent from manhood to godhead. Greek philosophy emphatically starts from human feelings and aspirations, and seeks out their proper object. Indian philosophy, as much as Indian mythology, is still occupied with speculations about divinity; would still be telling us how the supreme powers have been working in creation, manifestation, or destruction. Undoubtedly there is here a point of analogy with the Hebrew writings which it is important not to forget—important, however, mainly because it enables us to see more clearly the difference between that which purports to be a revelation of God to man and through man, and that which treats of the relations of God with the outward world, and with man only as a portion of that world. The former could meet that healthy portion of Greek inquiries which respected the life and the wants of man; the second might easily present itself as something fitted to complete those theories about the universe, which we have seen were some of them so splendid, and all of them so baseless.

These observations are necessary, not merely that we may understand the course of thought which the writers of the Christian church followed, but that we may not be misled respecting the feelings and inquiries of those who were endeavouring to cultivate and maintain the old Greek philosophy. Were we writing a history of the church, or of theology, it would behove us first to speak of the forms of thought which are to be discovered in Christian writings, and to look upon the different notions and systems which were afloat in the world, as bearing upon these and illustrating them. The student of philosophy will probably pursue the opposite method. He may wish to know first what men were doing who had no connection with the new faith, or were opposed to it; he will then think himself better able to judge whether the church was really meeting the wants of the period, or whether she was moving along in a region of her own, unconscious of them or despising them. Now in quarters which that Indian influence can scarcely have reached, or in which the traces of it are most difficult to discover, it will still be seen that the philosophical tone had undergone a remarkable change. The dry bones of Stoicism we found had been endued with a temporary life by the old republican spirit of Rome. When that spirit had departed, it might have been supposed that they would have crumbled at once. But this was not the case. Infinitely more genuine as Cato and Brutus were than Seneca, it is yet true, (and the affectations of the man only make the fact more remarkable,) that there are conceptions of a higher

kind in his books, than in those of his elder and better countrymen. Granting that they are conceptions merely, still they are indications of that being at work in men, which might find a real meaning for itself somewhere. A parasite in the age of Nero had thoughts respecting the assimilation of man to the divinity, respecting self-restraint and self-denial, which the honestest Roman in the age of Cicero had not. If we trace the progress of this same Stoicism, we find it again uttering, in the language of Zeno, feelings and aspirations of which he had known very little. Something more than the idea of a victory over circumstances—the idea of a victory over inclination and self—had dawned upon the mind of Epictetus. His conception of the philosopher's life may be as solitary, as little in the proper sense of the word human, as his master's. But the standard is evidently sublimer, and the sense of the difficulties to be reached in attaining very far more clear. Lastly, if, still following the same track, we look at the writings of the imperial sage Antoninus, it is difficult to say how far we have risen above the little frivolous maxims of conduct, "the hints for nurses," upon which the older teachers of the Porch prided themselves. Internal purity, practical affection and benevolence, contemplation of the divinity, nay, even humility itself, are not barely recommended in his writings or inculcated in formal precepts; it would seem there was an habitual aspiration of his mind after them.

And all these fine thoughts, high feelings, doctrines about the capacities of the human spirit, longings after emancipation, were awakened amidst the intense and loathsome corruption of the empire! Most strange whence such dreams should come, most strange that if they came they should have been accompanied with no longings for the improvement of the world's condition; that each sublime philosopher should have been content with thinking how he might get himself out of it! There were those who felt the contradiction, benevolent spirits who wanted something else to contemplate than visions of their own possible perfection, and who could not find it in the society around them. Such a person we conceive was *Plutarch*, who should be considered not so much a philosopher, as a kindly gentle antiquary looking out in the past history of his native land, as well as of that which had adopted it and the rest of the world, for specimens of courage in action or beauty in character, and then, in the same spirit, searching in the writings of philosophers, the sayings of poets, the fables of mythologists, for any thing which could sooth the spirit, inspire pleasant anticipations, make the contemplation of present evils less oppressive, and offer some prospect of real and permanent goodness. For this is common to him with the sterner Stoics of whom we spoke just now, and distinguishes both alike from the teachers of the preceding age, that the contemplation of some ideal of goodness seemed to them to be necessary for the life of men. So that a singular revolution had taken place. In that which we called the sceptical age of Greece, the age which produced the sects, all questions respecting the absolute and the ideal ceased as a matter of course. It was not proved, but taken for granted, that they meant nothing. In this age it was not proved, but taken for granted, that they meant almost every thing. An impulse which they could neither account for nor control was urging all the earnest men of the time, in whatever sect they might have been educated or whatever opinions they

might be inclined to patronise, in this direction. The only exceptions were those which must occur in every age and were nowise characteristic of this; a set of men who were entirely occupied in writing commentaries upon the letter of ancient philosophy, and another set who were devoted chiefly to medical inquiries, and who by degrees came to disbelieve in every thing for which they had not the evidence of their senses.

Miraculous
teachers.
Apollonius
of Tyana.

But neither the ideals of character, which Plutarch took delight in contemplating, nor his merely antiquarian philosophy, sufficed for the wants of this period. It was haunted with a continual sense of the need of some higher and more immediate inspiration, of some person in whom there should be a divine as well as a human element. Accordingly, about the close of the first Christian century, a strange person floats dimly before our imagination, to whom a hundred years after strange acts and qualities were attributed; who was supposed to combine, in a wonderful manner, the philosophical with the miraculous character. It is better to leave Apollonius of Tyana surrounded with the cloud in which it has pleased his worshippers to envelope him, and not to make any efforts to reduce him within the forms and dimensions of an historical personage. In that shape he best illustrates what necessities the time was conscious of, and what kind of methods it could devise for the satisfaction of them. The name and the legendary acts of Pythagoras appear to have furnished the investiture of the modern teacher; a circumstance which deserves to be noticed, not because any person possessing the least sense of justice would more think of attributing to Pythagoras the doings of Apollonius, than of making an ancient saint answerable for the conjuring tricks which a modern monk may have played with his relics; but because it shows how much men in that time were struggling to connect themselves with the past age, and to recover by that means, if by no other, the feeling of a union between themselves and the invisible powers of which the ancient men spoke. The particular philosopher selected on this occasion may indicate that the mystery of number and the idea of a society based upon a *unity*, which should not mean merely *singleness*, were haunting in some strange manner the mind of that generation.

The new
Platonic
school.

These thoughts, however, as we have seen in the former part of our sketch, had only their root in the speculations and practical experiments of Pythagoras; their full blossom in the Dialectics, the Physics, but above all, in the Polity of Plato. It cannot be surprising, then, that in a period which had already exhibited such tendencies, a new form of the Platonic philosophy should have speedily developed itself; and instead of appearing, like Stoicism and Scepticism, in a few detached thinkers, should have embodied itself in a school which lasted for several centuries, and which has always been felt to mark the philosophical character of a whole period.

Numenius.

Among the less known persons who seem to have laid the foundations of this school was Numenius, a Syrian. From what part of the East he derived that new element which was to mingle with Greek philosophy, may be judged from a saying of his, "that Plato was but Moses speaking Attic." In strict consistency with this observation, the great question which occupied him was, it would seem, that which occupied Philo above all others—the necessity of two beings; one God in himself, the other God in relation to men and to the world. The idea of some third power, as necessary

to connect both with the actual movements of matter, seems also to have presented itself to him. In these thoughts lie the germ of the new Platonic school, the founder of which, however, was not Numenius, but Ammonius Saccas of Alexandria, about whom a great controversy has been waged, whether he were or were not a person of that name who apostatized from Christianity to Paganism. The question is not of much importance to our purpose. We shall see presently what relation the ideas of modern Platonism bore to those of Christianity: whether they were offered as substitutes for the Christian mysteries, or worked themselves out in the minds of men as the legitimate conclusions from Plato's premises, the same question must still be asked, which of the two best meet and fulfil the necessities which Plato discovered in himself, and affirmed to exist in all men? For this was the object at which this philosophy proved itself to be aiming, as soon as it had acquired shape and consistency in the hands of the great disciple of Ammonius, Plotinus. This remarkable man saw clearly that Plato is continually pointing us to a ground out of and beyond ourselves. He felt, though with less clearness, for the habits of his mind were not scientific, that Plato has pointed out a method by which our thoughts may travel in the right direction towards that ground; but that more than this he has not done, and could not do. Plotinus perceived that the ascending series of human seekings must be met by a descending series of divine revelations or inspirations. While, therefore, it was the pursuit of the divine the ineffable unity, which was to be the object of all desires, and the satisfaction of all wants—while it was the privilege of the divine philosopher to enter into the immediate vision of Deity—all forms of mythology, the old Greek forms especially, but without prejudice to any that might be derived from the East, were to be pressed into his service. Necromancy, witchcraft, all methods of dealing with the unknown and the wonderful, were to be studied and resorted to by him. It is very true, nevertheless, that the philosopher did in a manner stand above all these things, fashioning and shaping them all into his great comprehensive theory; so that all the practical working religions of the world had existed for the sake of bringing forth a great metaphysical idea. That idea is of a primary essence, which is the One, a product of this which is the Reason, a third emanation from the reason, which is the Soul. It is an interesting question how far Plotinus could directly deduce this idea from the writings of Plato. In our sketch of that great man's speculations we made no formal allusion to his belief, or supposed belief, of a Trinity, such as that of which Plotinus spoke. We were much less anxious to set forth any particular results and conclusions at which he arrived, than to make our readers perceive by what steps he was led to acknowledge a Being in itself, a distinct utterance of that being implied in self-existence, and necessarily distinct from it, and some spiritual but most actual bond between that which is self-existent, and that which is uttered, if the idea of Unity is not to be sacrificed in the very effort of arriving at it. This principle, we say, is involved in all the scheme of Plato. He was led on by degrees into the scientific exposition and developement of the principle; but that which chiefly weighed upon his mind was a sense of its practical importance, as the only deliverance from the two opposing doctrines of an absolute being, which excluded

all knowledge or intuition, and of a perpetual flux and uncertainty in things. Hence it is in the applications of this truth to the controversies and sophisms of his time, for the purpose of proving that man may attain knowledge, and yet not have the standard of knowledge or truth in himself, that Plato's art chiefly consists, and that we become acquainted with his meaning. It followed that if Plato preserved his idea merely in the metaphysical form, it still retained the most substantive and practical value; and this made him the less reluctant so to leave it, and only now and then to intimate in some casual hint, or beautiful mythical story, that if it were a true metaphysical idea it must be more, that in some way or other there must be a point of union between it and that national theology with which he felt that all his speculations and discoveries did not enable him to dispense. The modesty and sincerity of Plato's mind are in nothing more apparent than in the two acknowledgments, which may be traced everywhere in his writings, that something more than philosophy is wanted, and that he himself had only a vocation to provide this.

Difference
between
Plato and
Plotinus.

But a time was come when the only test which could be given of the soundness of a metaphysical idea was its capacity of coalition and coincidence with moral and personal realities. Precisely the same necessity which drove Plotinus to incorporate old revelations or supposed revelations with his philosophy, drove him to seek a local habitation and a name for the principle which Plato had enunciated. In making the attempt, however, Plotinus forsook the footsteps of his honest master, and became an imitator of those parts of his writings in which he had most departed from his own principle. We have seen how in the *Timæus* the subtlest of European intellects fell into a kind of Asiatic vagueness and confusion. Plato, the cosmogonist and theogonist, is another man altogether from Plato the seeker of hidden truths in the facts which lay before him. And it is this side of Plato more than the other which is presented in the speculations of the new school. Mythology, therefore, which Plato received as a witness of something that must be, as the tradition of actual communications which had been lost or perverted, or as the attempt to supply a chasm, which nothing but some divine announcement could fully close up, was grossly adopted and defended with a passionate vehemence which he had never exhibited, and yet ever and anon explained into philosophical allegories in the very manner which he, in the *Phædrus*, had so evidently censured. Nor let any one hope to take away these phantastic portions of the Neoplatonic system, and yet to leave the rest of it consistent and entire. The school passed under the hands of many masters, all able and ingenious men, but this separation never could be effected. If any one thought of attempting it, he speedily discovered that the whole scheme must crumble, leaving nothing but those Platonic principles which demanded something from above to satisfy them, but did not pretend to supply it. It was a far more reasonable prayer of Plotinus, that the Emperor Gallienus would be so good as to establish a city on the Platonic model. The sage felt that he wanted something more than a compact theory, framed out of all the mythologies and philosophies of the earth—that some how or other his system, if it were a true one, ought to be able to embody itself in a living society. Doubtless the experiment was worth making; but the

Emperor, though exceedingly well disposed to all philosophical devices and inventions, declined the honour of undertaking it. When Julian determined to invest philosophy with the purple, the same fanatical zeal for the old gods still characterised him and all his teachers. It was felt to be even a more indispensable part of the system then than in the time of Plotinus; but he did not live long enough to establish a Platonic republic.

It would seem thus far, that the primary elements of the philosophy of this period were derived from Hebrew and Greek sources, and that any influence which may have been exerted upon it from any other quarter rather modified its outward shape than changed its essential character. We can easily understand how Indian theories about the creation of the world, Indian confusions between God and the world, may have mingled themselves with all the courses of thought to which this period gave birth; we can find no warrant in history or in reason for supposing that these theories and confusions gave the impulse or even the direction to any one of them. It is much easier to explain how the habits of thought which had for some time characterised the natives of Persia, should have acted strongly upon the minds of both Jews and Greeks. Accordingly, those who have treated of another leading feature of the philosophy of this period, its *Manichæism*, have had no hesitation in referring to the Persian doctrine of the conflict between a good and evil principle as the sole origin of it. We are very far from wishing to set at nought so general and long established a tradition as this; yet we think that the true nature of this important doctrine cannot be understood, unless we see how it was connected with inquiries which we have described as going on in regions subject to a set of influences entirely different from those which prevailed in Persia; and unless we consider what relation it bore to those controversies which we have spoken of as especially marking the temper of this age.

When we spoke of Socrates as the person who ascertained the meaning of those truths in practical life which previous Greek philosophy had been aiming to find, and which subsequent Greek philosophy was seeking to expound, we noticed especially, the way in which he was led to feel the existence of two principles within himself, one struggling upwards, the other gravitating towards the earth, and how all his moral discipline had reference to this discovery. That sense of a contradiction in things, which from the first had haunted the minds of Greek inquirers, was now transferred to its proper region; the observer's soul was felt to be, itself, the centre of this contradiction. But when Plato had pointed out the universality of those principles at which Socrates had arrived through personal experience, when he had shown how Being was the object after which the higher part in man is striving, and how it is mocked in its efforts by semblances and counterfeits, it became necessary for him to inquire how far, seeing that the true object has a reality wholly distinct from the mind of him who beholds it, a similar reality was to be presumed in that which is opposed to it. This question is discussed in a dialogue to which we very briefly alluded in a former page, called the *Sophist*. There, it may be remembered, this idea was gradually developed, that Not-Being must practically, and at whatever hazard of seeming logical contradiction, be contemplated as in some sense real. There is, perhaps, scarcely a more

losophy.

instructive or useful instance in the records of philosophical inquiry than this of the force by which an honest man, who follows a safe experimental course, is urged to conclusions which, to the mere intellect, seem most paradoxical, but which the conscience and reason affirm and recognise. Further than this, Plato seemed not to go; and, as usual, he did not translate his metaphysical idea with any definiteness and dogmatism into the language of morals and theology, though it was a moral feeling which had led him into it, and though he felt that, like every other absolute truth, it must in some way be connected with theology. It is a point not perhaps easily resolved, what relation there is between this part of his speculations and that which is presented to us in the *Phædo*. That he felt the body to be the prison-house and grave of the spirit, in the emancipation from which man's freedom and his full capacity of enjoying the vision of pure being begin, is undoubted. But that he therefore looked upon Matter as identical with that "Not-Being," of which he speaks in the other dialogue as, in fact, essentially evil, can by no means be inferred from his language. It was a subject on which he probably felt it unsafe to dogmatize, and on which, when he was viewing it from different sides, he may have expressed himself very differently. There is a much nearer approximation to this doctrine in Aristotle. As Being did not present itself to him in the same absolute way as to Plato, he was much less able to conceive any direct positive opposite to it. Form and matter were his two great contraries, and in the latter he certainly believes the capacity of evil to reside. Still he goes no further than to say, "without matter there could be no evil;" and, as we have remarked before, it is but in a modified sense that he attributes eternity to it.

How con-
nected
with Jew-
ish life.

The questions then with which Manichæism is conversant had presented themselves in every form to the Greek mind. The existence of two contending principles in man, those principles having each their counterpart and origin in that which is above man and distinct from him, and the connection of evil with matter,—these subjects had exercised and tormented the minds of men who had never heard of Arimanes and Oromasdes. That the *Jew* had been led to feel in himself, and to see in others, a mighty conflict, that he had felt all his good desires striving after a divine object, all his evil desires connected with enemies against whom he was to cry out for deliverance, it must be surely superfluous to remark. His whole life, personal and political, is the carrying on of this conflict, and the more his views expand, the more clear intuition he has of a perfect being and of a divine order, the more the sense of an opposing kingdom of disorder, and of an evil Will presiding over it, dawns upon him. If then we only suppose these two great lines of thought by some means to have been brought to a meeting point, so that neither could any longer be pursued separately, we should be able to account for questions about the absolute relations of good to evil, and about the way in which matter was connected with either, even if we had no help from Persian mythology or philosophy. But since we have admitted that they do enter into the history of Manichæism, and do in some measure define its nature, what place do we assign them? We answer, Manichæism is precisely the attempt to frame a theory about good and evil from the contemplation of the universe, without any practical experience of human conflict. Now this is the

characteristic which we remark in every Oriental theology but the Jewish—that it is exactly a speculation more or less ingenious, more or less suggested by actual recollections of a former revelation, or by the intuitions of men really aiming at truth; but unconnected with a human education, with a human life, not grounded upon a direct connection between God and man, but upon certain assumed relations of God with the world. The acknowledgment of two conflicting powers, both equally Creators, but one creating for good, the other for misery, is the natural and inevitable result of this method of thought; and this acknowledgment compounded with various conceptions, drawn sometimes from Judaism, sometimes from Greek speculations, sometimes from Christianity, about the different subordinate powers which these primary principles had called to their assistance, and about the final issue of the struggle, constitutes Manichæism.

We have thus noticed the principal topics which should engage the attention of one who is studying the philosophers of this period, endeavouring as much as possible to keep them distinct from the history of the Christian church. We must now as briefly as possible fill up our rude outline by noticing how at each one of these points it came into contact with thoughts and feelings which had been working from the most different directions.

And first, as we began with the revival of Stoicism, and the noble attempts which it made at a victory over accident and circumstance, over the fear of men and the dread of death, we may just allude to the practical life which was going on in the heart of the Roman empire, in the days of Seneca, Epictetus, and Antoninus. We are writing a sketch of philosophical inquiries, not a martyrology; but as these Stoics made it the test of a sound system that it should produce high actions, it cannot be out of place to remark that, by some means or other, men and women were enabled to evince a constancy in suffering, and a victory over ordinary inclinations and terrors, which these philosophers had scarcely dreamed of; that they were able to do this, not only without having the sense of being very great, heroic, and wonderful characters, but with a feeling of shame and humiliation, and thankfulness for a privilege to which they had no claim; that they were not obliged in order to compass this high standard of personal perfection to separate themselves from the rest of mankind, or to regard their welfare with no interest; but that, emphatically, they were members of a society, and looked upon their own acts as means of establishing that society, and spreading its influence over the putrid mass around them. And this we are bound to take notice of, not merely for its own sake, but because this high and transcendent form of morality was intimately and inseparably connected with the contemplation of an ideal of absolute goodness, and therefore throws as much light upon the forms of thought in this age, as upon its outward history.

For we noticed, secondly, a tendency in this time, which the writings of Plutarch especially develop, to look back at past models of greatness as some relief from the miserable spectacles of degeneracy by which the philosopher was surrounded. And we observed that this sympathy with past ages was nevertheless found to be inadequate; that some model, in whom the greatness and wisdom of past ages should reproduce themselves, one too in whom there should be something of mystery and divinity, must be found or created in that very time. The Christian church, taught by that very apostle who had been the great herald to the Gentiles that they

were not of a new but of an old stock, grafted into the privileges of the commonwealth of Israel, felt that all the heroes of the Jewish nation were of their own kindred, that they were set before them as examples of faith, struggling under all circumstances of prosperity and disaster; that they had not to take refuge in the contemplation of them from the sense of their own fall and decay, but could sympathize with them because they were called to exercise the same trust under still greater discouragements; lastly, that all these witnesses of the presence of God with men, and of his relation to them, had been leading up to one complete and consummate manifestation of him in the flesh of Man. If they had merely considered their position as heirs of Jewish privileges, or had merely been engaged in conflict with those who believed that the promises to the fathers had not been fulfilled, this fact of the incarnation would still have been the central one in all their thoughts and teachings. But very soon they discovered that it was this fact too which was their only resting point against Greek opposition, and the only satisfaction of Greek cravings. So deeply had the feeling of a divine humanity penetrated all the fables, as well as all the deeper speculations of Greece, so readily had it incorporated itself with those meditations which Philo owed to the Hebrew Scriptures, so strangely was it found to conspire with some of the rude and fantastic dreams respecting the creation, preservation, and destruction of the world, which had their home in other parts of the East, that when this fact was held forth by the Christians as one which they were commanded to promulgate, it naturally struck the philosophical Greeks as the new and grotesque form of an opinion which had been familiar to them from their infancy, though they never perhaps had so distinctly contemplated it before. Hence the obvious resource of setting up the theory or opinion of a divine humanity as the substitute for and contradiction of the assertion that the divine Word had taken flesh, and dwelt among men. The hint of this method of opposition having been once given, speedily a system began to shape itself out to which the religion of every region of the earth contributed its quota, a system which assumed the most enormous and contradictory forms, in which Judaism, Greek Pantheism, Hindooism were each by turns uppermost, which had no positive centre, but had for its negative centre the doctrine that Christ had *not* appeared in the flesh of man. This Gnosticism presenting itself to those who had never heard of philosophy, but had embraced Christianity as that which their consciences had need of, startled and staggered them; being presented to those who had a smattering of philosophy, destroyed their faith, and set them upon making the already heterogeneous compound still more shapeless by amalgamating with it some of the doctrines which they had learnt in the church. Philosophy thus appearing as the direct and formal antagonist of Christianity, it was natural that one class of the Christian fathers should turn away from it with some abhorrence, and should be kept in what was for them an useful ignorance of the fact, that in proclaiming the doctrine which was revealed to babes, they were also teaching the very one which sages were in need of. It was well that there should be such a class, for thus the fact was preserved in its simplicity, and it was manifested to the world that on this fact a polity was standing which all the polities of the world could not destroy, and for which all its theories could provide no substitute.

The incar-
nation the
centre of
Christian
faith and
teaching.

Gnosticism.

But it would have been equally strange if this had been the feeling of *all* those who were appointed to watch over the cradle of the infant church. It was surely to be expected that converts would enter it who had not merely found the fables of paganism incoherent and false, but who had been also through the sects of philosophy seeking rest, and finding none. Such men would surely have been doing great violence to all that their experience had taught them, would have been offending against real simplicity, while in the act of counterfeiting it, if they had passed by those metaphysical questions respecting Being and Unity which had occupied them in the schools, or had proclaimed that with these the truths which they had been taught at their Baptism had no connection. To have said so would, in their case, have been to have practised the grossest fraud on their Conscience and Reason. They felt that there *was* a connection, a very intimate connection which revealed itself more clearly every day, to those especially whose position at Alexandria brought them into contact with the speculations of Plotinus, Porphyry, and the new Platonic school. How could men, who were taught to declare that communion with Him whom they worshipped was the highest and most glorious privilege of the creature, turn away with indifference when they heard this very doctrine proclaimed in the schools of philosophy? How, when they heard these philosophers recurring to the ancient mysteries as witnesses of this privilege and means of obtaining it, could they forget that they had mysteries intrusted to them of which this was the meaning and the end? How, when they heard them speaking of a Trinity as not inconsistent with, but the very condition of an ineffable unity, could they turn away and say, "There is *no* relation between these thoughts and that awful name into which we are baptized?" Such language may sound simple to modern ears; in these Fathers it would have been the excess of affectation. Surely it was greater homage to their faith to say, "This communion which you philosophers talk of as meant for some of the sages of the earth, we declare is accessible to the poorest peasant, because it has pleased God to establish it in the person of one who was himself poor and suffering: these mysteries whereby we admit men to it, are indeed high and dreadful, but dreadful from their very simplicity; the difference between them and those to which you have recourse being precisely that which Plato pointed out between the darkness of the Sophist and the darkness of the pure philosopher, one dark from the clouds which he gathers round him to conceal the light, the other dark from the excess of light in which he dwells. Lastly, this Trinity, in which we too alone behold the perfect unity, is not with us a notion, not the description of certain qualities or attributes, but the name of a Living Being presiding over the cradle of every child as well as the final object of the faith, and knowledge, and love of every perfect man; nor this only, but also the foundation of a kingdom which is daily expanding its borders, despite of all resistance from the powers or the wisdom of the earth."

This last was a practical argument which did, no doubt, affect the minds of the Neoplatonists more than all that Clemens or that Origen could say to them. When they saw that a universal republic could not be set up on this theory of unity, but that a universal republic had been set upon the foundation of that unity which was proclaimed to the world by fishermen, when they saw that the patronage of Emperors had not availed to

keep on foot the old religion even in alliance with the new philosophy, but that Emperors were compelled to do homage to this unintelligible faith and fellowship, and to exalt the cross above the eagle, they must have felt at times that more than human logic and eloquence were contending with them. And soon they had to see the two systems brought to another and still more striking test. It might be hard to conjecture how the Christian church, when acknowledged as a power in the empire, should be able to furnish the same evidence of its stability which it had given in its days of weakness and obloquy. But such an occasion arose. A single man was called upon to maintain that to be a substantial truth, which Plotinus and his school recognised as a metaphysical idea. Against priests, against rulers, against apostatizing friends and violent enemies, against meek men who wondered that so much pains should be necessary to assert a mere dogma, against dogmatists who really cared for nothing but the logical form and therefore perverted that, did Athanasius maintain in synods, in palaces, in dens and caves of the earth, the principle upon which the Christian church rests. Strange spectacle for all men to witness! strange above all for those Platonic philosophers who could talk indeed of their Trinity, but who never dreamed that mankind could be interested in the assertion of it, or that they were to make any sacrifices for mankind. The warrior lived on through the days of Julian, lived to see the utmost done that could be done for Platonized paganism, and lived to see the principle, for which he had fought at such mighty disadvantage, recognised and triumphant.

Augustine.

The relations of Christianity to Manichæism were to be brought out by a fighter of another kind than this, but not a less brave or desperate one. The Christian Fathers, who had hitherto been in contact with philosophy, were, as might be expected, the Greek—especially those of the Alexandrian school. The early Latin Fathers, seeing the speculations of Greece chiefly as they were expressed by Romans, or embodied in Roman practice, would be likely to deal with their outward effects rather than very carefully to investigate their nature; to attack the outward forms of Paganism rather than to inquire in what way the thoughts connected with those forms might have been preparing the way for Christianity. But when the Western Empire was exhibiting every day more certain symptoms of approaching dissolution, the Western Church began to assume a higher position, to understand more clearly its dignity, and to feel some deeper sense of its vocation as the power which was to establish a new form of society among the European nations. Augustine is the great representative of this feeling. It could not be a question with this great man whether he ought or ought not to take an interest in philosophical inquiries. Nothing less than an impious disregard of all the processes of his education, and a determination not to use the peculiar powers with which he had been gifted for the good of mankind, could have led him to neglect the subjects with which other men were occupied as not belonging to the province of a Christian theologian. The earliest direction of his thoughts, after he began to think earnestly and steadily, had been given by the Manichæans, and his personal experience wonderfully fitted him to enter into the very heart of their inquiries, and to understand that livingly, about which they theorized. Accordingly, various as were the questions which exercised him both after and before he became a

bishop, and large as was the sphere of his practical duties as well as of his thoughts, we may easily perceive that the question as to the nature of evil, its relation to matter, to man, and to God, was the central one in his mind from the very beginning of his life to the close of it. It has happened, unfortunately, that the controversy with Pelagius is that which, in modern times at least, has been regarded as his peculiar work, and that too little endeavour has been made to connect the writings which bear upon it with those which belong to the earlier periods of his history. From this partial conception of his character, some mistakes have originated; he has even been supposed to have darkened or denied some of the very principles which it was given him most clearly to perceive and elucidate. One might fairly say, that the Socratic doctrine of a living spirit in man, against which his nature is in constant conflict—a spirit striving upwards after the perfect good, as that nature is always dragging it down into an abyss of evil—of which no account can be given except that it is the contradiction of all good all order all unity—was the most prominent in his mind. This drove him to Christianity, because it alone taught him how He, who is the perfect good, has met the struggling spirit, has redeemed it out of its bondage, has endued it with strength to resist and to triumph. To bring out this principle in clearness and power, and to use it against Manichæism, by showing that the evil principle cannot be an original principle—cannot be a creator, but can only be contemplated as apostate and destructive, was his first great object. Next it was his aim to show how, in the personal conflict wherein man is engaged, the subjugation of the animal nature is necessary in order to the victory and deliverance of that spirit which is looking upwards, and how the degradation of the spirit to that animal nature has brought all corruption and degradation into it; and yet how different that degradation is from the essential pravity which the Manichæans attributed to matter; how entirely it has been the result of the conjunction of matter with a fallen will; how reasonable it is to believe that the restoration of that will is the precursor of a bodily deliverance. These great principles, which he had been all his life illustrating, were, in fact, the very truths which enabled him to resist Pelagius when he confounded the relations of nature and spirit, and supposed the possibility of some good in the creature, viewed in separation from the Creator. But they had, no doubt, to be presented in a somewhat different form from that which they had taken in the controversy with the Manichæans. That side of his faith, never absent at any time from the mind of Augustine, which concerned the dealings of the Creator with his creature, and the derivation of all good from Him, had now to be put forth with a prominence which the eagerness of controversy might easily make exclusive, nay, which might even lead Augustine himself to look back with fear on some of his former statements respecting the spirit in man, and its longing after the perfect good. These, nevertheless, just as truly as the other, expressed his real heart; and, without them, the other, even as confutations of the Pelagian doctrine, are practically ineffective.

We have shown then, we trust, that Manichæism, as well as Neoplatonism, the antiquarian philosophy of Plutarch, and the exalted Stoicism of Epictetus, had their counterparts, and their only satisfactory interpretation and realization in the Christian church. We have

rality.

no greater wish than that our statements should be thoroughly sifted, and that they should awaken the reader to pursue a course of study which will, if they are false, expose and refute them. Unquestionably they are not those which he will receive from the majority of modern writers who have treated upon the subject. Either he will be told that the Christian Fathers most wickedly and mischievously polluted the pure wells of Christian truth by mixing with them the fables of Platonism; or else that they followed an ideal perfection to the neglect of practical morality; or, lastly, that they made philosophy merely a branch of theology, and thus as well deprived it of its scientific form as took away all the energy and freedom of the human spirit in pursuing it. With respect to the first of these charges, we earnestly request our readers to consider whether what are called the fables of Platonism were or were not the questionings of the human spirit respecting the most awful subjects which can occupy it; respecting its own constitution; respecting the object for which it exists; respecting that which is, and which is to abide, and that which merely appears and is to pass away. What avails it that some men, busied in their books or in their merchandise, shut their eyes and say, there are no such questions; that they mean nothing; that only fools would dream of them? History declares that there are such questions; that they have tormented the minds, not of fools, but of the most sagacious, considerate, and, in the true sense, practical men that the world has ever seen. To set at nought this evidence is not to say we do not care about philosophy; it is to say we do not care about facts. But if these be real and not mock inquiries, they then refer to subjects respecting which a revelation should give information, or to subjects on which it may be expected to be silent? If to those on which it should be silent, then let us know on what subjects it ought to speak; if it has actually spoken upon them, then let us know how the stewards of this revelation could be simpler or wiser men for not setting forth what it has said. The accusation, in fact, proceeds on an entirely false assumption. It pretends that the early Fathers did not think that the revelation which God had given was adequate to the wants of his children, and, therefore, that they sought to help it out with human philosophy. The truth is, that they were putting contempt on human pride by declaring that the highest mysteries it had ever dreamed of were contained in the creed which they taught to their Catechumens.

The second complaint of the ancient Christians that they set up an heroic morality to the exclusion of the homely and practical morality, we have already answered by anticipation. We have admitted that it was not the work of this age expressly to inculcate the relative duties; that, from first to last, the most evident indications of Providence marked out for it a different (we do not say a higher) vocation. But unless it can be shown that those relative duties have another safer resting-place than that of those absolute principles which were in this period brought to light and practically exhibited, we shall be curious to know what proof of reverence for such duties these persons furnish who are impatient of any moment which the divine wisdom thought fit to occupy in preparing the ground for them. We are fully convinced that the history of a subsequent age, of which we shall have to speak by and by, furnishes the truest answer to these heartless murmurings, and teaches us

how long relative morality is likely to last when it looks up to nothing higher than itself.

But if neither theology nor morality suffered in the hands of the early teachers of the church, must we not at least concede some force to the third objection, that they dealt unkindly with philosophy? This question, like the two former, we believe, is best answered by history. We acknowledge that a scientific form of thought and a clear apprehension of our distinct faculties were wanting to this age, as readily as we acknowledge that a direct formal acknowledgment of the dignity and importance of human relationships was wanting to it. We acknowledge further that it was characterised by an ignorance of the laws of nature as great as that which existed among the earlier Greeks. Once more, we are firmly persuaded that scientific forms of thought, a knowledge of our own faculties, and an acquaintance with the principles of physics, are intended for man. But if we are further convinced that no acquaintance with the conditions of science, with our own faculties, with the outward world, could have been attained unless some satisfaction had first been provided for those questions which belong to the sphere of real knowledge—those questions respecting absolute permanent truth, which the Platonic philosophy raised, and which were exercising the minds of all men, however different their education, in that day—we are not, we think, testifying any indifference to that wherein this age was weak, when we say that it did not injure philosophy but sustained it, by its theological decrees and determinations. And if we are further convinced that when any one of the after ages has tried to undo or do again that which this age accomplished, its own work was lazily performed, or not performed at all, we are not, surely, looking spitefully upon the progress of the human species, but seeking to promote it, when we ask men to turn with reverence to the past, and to consider whether it is not a wiser and safer course to be thankful for the deposits which it has bequeathed us, than to be slandering it because it has not performed all tasks, and so left us to utter idleness.

It was in the reign of Justinian that the schools of Greek philosophy were finally suppressed. Many circumstances mark this out as a very important crisis in the history of the world, indicating wherein the period which was afterwards to commence would differ from that of which we have been speaking. A Greek emperor obtaining dominion, through the conquests of his generals, over Italy might seem to promise that the empire was once more to be consolidated, but that it would no longer have a Roman character. On the contrary, this very Emperor becomes the silencer of that philosophy which had been the distinguishing mark of Greek life for above a thousand years; and arranges, sanctions, and stamps with imperial authority, that law which had been as characteristically the badge of Roman greatness for about the same period. The effects of these proceedings might not be felt for a long time: the first was not in itself very important, for the schools of philosophy had worn themselves out, otherwise, no Justinian could have destroyed them. But both were significant, and, speedily, other more important events interpreted their meaning.

A right understanding of Mahometanism, and of the circumstances which assisted its propagation in some countries and retarded it in others, would be a great help in comparing this period with the one that follows

losophy.

it. We observed that a tendency towards the contemplation of that which is divine and absolute, though in a certain sense characteristic of all men in this time, whether they were heathens or Christians, was very much more conspicuous in the Greek Fathers than in the Latin. The latter dwelt upon the fact of the Incarnation, and in doing so were led inevitably to teach that a transcendent kind of morality, not determined by formal precepts or by the ordinary social bonds but grounded upon assimilation to the character of God, had now become possible for men. Still it was with this fact as a part of divine history, and with the moral results from it, that they occupied themselves. On the other hand, it was the inclination of a very important section at least of the Greek church to dwell upon the consequences of this same fact as opening a vision and intuition of the Infinite and Eternal, as lifting men actually into that region which philosophers had dreamed of. Thus these two classes of men, starting from the same point, were drawn, one more to the human, one to the celestial side of the truth which they held in common. In the writings of each might be traced certain characteristic infirmities to which these respective habits of thought made them liable, and what were suppressed or only broke forth at intervals in the leaders and guides, were likely to become the prominent temptations of the bodies which they represented. In the Greek teacher might be traced little more than that impatience of common facts, and that dread of every thing anthropomorphic, which we observed in Philo. Among the people this inclination would easily give birth and countenance to heresies, of which the object should be wholly to set aside or to reduce into the merest vapour the idea of an actual divine humanity. However successfully these might be repressed by the arguments of doctors or the decrees of councils, the spirit of them had unquestionably entered deeply into the Greek mind and character. Now, seeing the morality of churchmen expressly depended upon the sense of a direct connection between themselves and their Creator; seeing that the other helps and appliances which later ages derive from a recognised standard of manners and a fixed form of Christian society were then wanting, one may easily conceive the instability and corruption under which the eastern Christian nations must have suffered when this faith was loosened or withdrawn. One can easily conceive how a form of faith, which asserted in the strongest terms the absoluteness of God; which utterly took away the idea of an incarnation; which furnished a code of precepts all plausible, many of them excellent; which came forth supported by a man really convinced of his own inspiration, at the head of a brave people who then for the first time felt themselves more than a horde—felt that they had really a principle to assert—must have made way among men who had lost their own faith already through an exclusive encouragement of that very habit of mind of which Islamism was the expression. It is equally manifest that those particular weaknesses which had appeared in the Latin church, weaknesses which laid its members open to the impostures of those who suggested a more rigid rule of life or who invented some human contrivance for encouraging devotion, did not make them liable to this particular infection. It is easy to say that they grovelled on the earth, and therefore were not liable to be misled by any hope of being raised to heaven. But such language would

Character
istics of the
Greek and
Latin
churches.

not be very appropriate or true. Augustine's contemplations were as lofty as those of any Greek. He as much aspired after communion with the perfect good; he even entered as deeply into philosophical speculations; and yet in him, as much as in any of the earlier Fathers, the Latin character is visible. His philosophy bears upon a great practical subject. It may ascend into the greatest heights, but it starts from the lowest ground, and is occupied with personal struggles. Another point too respecting him is worthy of note. He deals more than almost any one with individual life and experience. In some instances he may seem, to many, to have too much individualized his language so as to affirm that of particular persons which can only be affirmed of them as members of a society. And yet with this natural inclination he was brought into circumstances, especially in Africa among the Donatists, which compelled him more than most writers to enter into men's position as members of a fellowship and subjects of an ecclesiastical government; and the most elaborate of all his books is that on *The City of God*. While then the eastern nations, in their exclusive pursuit of that which is divine and transcendent, fell into Mahometanism, or hovered for some centuries on the verge of it, we may expect to find the Latin nations exposed to another class of very serious dangers from their too human propensities. But we may expect also to find, that whereas the one remained in a hopeless stationariness—even those who retained their Christian name acquiring a dull stupified character—the Latin people would shape out a course for themselves in many respects strange and new, but yet naturally arising out of that which the former age had traced and finally coinciding with it; that whereas Islamism, by excluding the belief of a direct intercourse between earth and heaven, lost the idea of an order and government of the world and necessarily became allied with despotism, the Christendom which rose up to oppose it would develop the ideas of Order, Constitution, and Law; and that by these the character of many other thoughts and speculations would be determined.

Moral and
Metaphy-
sical Phi-
losophy.

From Charlemagne to the Reformation.

In former portions of this *Encyclopædia* there have been elaborate discussions on the fortunes and writings of those who have acquired the name of the *Scholastic philosophers*. Even, therefore, if the limits of this sketch did not positively preclude such an attempt, we should have no excuse for entering at any length upon this subject. But we must carefully guard against the notion, that the space which we assign to this portion of philosophical history is any measure of the importance which we attach to it. Far from adopting an opinion, which was prevalent at least till very recently, that the questions which occupied the schools were trivial, senseless, and now wholly obsolete, we think it is difficult to overrate their intrinsic value, or the influence which they are exercising upon ourselves at the present moment. The persons who use the words Ontology or Nominalism and Realism with a sneer, little know how much those difficulties of which Ontology treats are besetting their own path; with what vehemence the controversy between Nominalism and Realism is carried on in their own minds and in the minds of all about them. We do not gain much by speaking contemptuously of our progenitors; we only contrive that we should suffer all the perplexities which they suffered

Scholastic
philosophy.

Moral and
Metaphy-
sical Phi-
losophy.

without the same consciousness of them which they had, and without their help in extricating ourselves from them. The mistake has been owing, we fancy, in a great measure, to a confused apprehension that the schools and the world have in all times, and had at this time especially, very little to do with each other. The fashion of scorning the active life of the middle ages is passing away; nay, is just at present giving place to a sentimental admiration. Men have discovered that something was done in this so-called dark time which we in our bright time could not well dispense with. But unless the speculative life of that period, besides obtaining the courteous treatment which it is likely to meet with under such a reaction, be viewed in connection with this practical life and shown to be inseparable from it, there is no chance, we think, of either being dealt with clearly and justly. A history which should do this would far more effectually expose the real evils of the middle ages and show whence those evils flowed, than all vehement party declamations against them which, being written without sympathy for the right, are very seldom successful in detecting the wrong. A very few hints as to some points which such a history might take notice of are all that we can furnish by way of comment upon these seven remarkable centuries.

When the
scholastic
age begins.

It has been a frequent subject of debate, whether the age of the schoolmen commences with the reign of Charlemagne, or not till rather more than two centuries later. Two remarkable men, it is admitted, arose within that period, to whom no thoughtful person would deny the name of philosophers—John the Irishman (Johannes Erigena) and Anselm; but it has been thought by many that there are characteristics in their writings which entirely distinguish them from the later schoolmen. This point, in which much of the character of this philosophy is of course involved, might, we think, be settled much more easily if the general history of the period between Charlemagne and Hildebrand were brought to bear upon it. It strikes one even at first sight that we are now contemplating quite a different world from the one which we were viewing, either in the time before or after the promulgation of Christianity. A race of men starting into social existence—these men coming under laws, submitting themselves to a new faith, beginning to understand what they were sent into the world for—how different a picture is this from that of the decaying Empire! Yet if we look again we are struck at least as much with the sense of continuance and permanence as with a sense of change. When we consider the materials out of which the new system was moulded, we find old habits of thought—traditions that had been dwelling for an unknown period in the woods of Germany—habits of subordination and temperance—a reverence for marriage—a military discipline—a worship of unseen powers with the strange institution of a week to commemorate them. If we look again at the power which was to work upon these materials, still every thing is ancient and venerable. Old Roman laws, Roman colonial government, the Roman sense of equity and obligation, the Roman language—these were some of the influences which were shaping the western chaos into a universe. And over all these, using them and subordinating them to itself, was a faith, which for eight centuries had existed in its present form, and was only the outgrowth and consummation of one which had been held by the Patriarchs in Mesopotamia. Besides these points of connection with the foregone time, there was a

VOL. II.

peculiar resemblance between these two first centuries and the kingdom which had been broken in pieces. A new western empire brought back many of the feelings which belonged to the military government of Rome. There was not yet merely a king of each nation, and an ecclesiastical head of Christendom. The king of one of the nations aspired to be the head of all, and to a great extent made good his claim.

Moral and
Metaphy-
sical Phi-
losophy.

It is commonly believed that Gregory the Great, the tamer of the Lombards, the establisher of a paternal government in Italy, the converter of the Saxons, was not a friend to letters. The charge has been disputed, and is, perhaps, much exaggerated. But were it true to the greatest extent, it ought not to detract seriously from the fame of this admirable man; it ought only to be taken as an indication of the circumstances attending the rise of society in the west, which it is important to reflect upon and to compare with others of a different kind. If, for instance, we contrast Gregory's alleged indifference to mental cultivation with the zeal for it displayed so short a time after by Charlemagne and Alfred, men certainly not more anxious than he to soften and regulate the characters of their subjects, we may gain much instruction respecting the feelings of this period.

Feelings of
Popes and
monarchs
respect-
ing the
methods of
improving
society.

Our first conclusion might be, that the ecclesiastic, as such, was the enemy of cultivation; the national monarch, as such, the friend of it. But this notion is refuted by all the subsequent history; nay, that history might even tempt us to assert the converse of such a proposition. The cause of the difference lies deeper. Gregory and Charlemagne alike felt that their subjects needed cultivation. They alike felt that this cultivation must be an ecclesiastical one; that the teachers of the nation must be those who had powers to act upon its mind. But the prelate thought that in the work of civilization the great instruments were those permanent truths which were delivered to men from heaven; the law-giver that men must be trained to understand themselves in order that they might know the necessity and blessing of obedience. These feelings never expressed themselves in such formal language as this; they might not be consciously present to the minds of either; but they were not the less real, and they found their utterance in acts. Gregory sent missionaries; Charlemagne founded schools. One sought to bring all nations into a universal society; the other laid a foundation for the cultivation of each nation.

To find out what relations existed between this universal society and the different national bodies which composed it was, it will be easily admitted, the great political conflict of the middle ages. We believe that the spiritual conflict was one closely connected with this. That there are certain longings and aspirations in our minds answering to the truths upon which the universal society rests, we have shown from the history of the Platonic philosophy through all its stages. But there is another state of mind which is connected with the sense of our being placed together under one order and government, of our being united in a distinct body under laws distinct from those by which surrounding nations are governed. Then comes the awakening of a sense of Personality; of that which is properly our Conscience; and, flowing out of this, a gradually growing Consciousness of certain forms and laws, to which our own understandings are subjected; and, later still, of certain Conceptions within us which must struggle onwards to birth. These are the particular character-

Political
and scho-
lastic ques-
tions in the
middle
ages.

Moral and
Metaphy-
sical Phi-
losophy.

istics which have accompanied the formation of every national society, or which may rather be said to be the formation of it. The problem, then, which all men were in one way or other seeking to solve in themselves during the eight centuries which we commonly call the middle ages, was what this sense of personality means, and how it was connected with or might be reconciled with those deep and transcendent truths which referred to the being and unity of God and his revelation of himself to man. And the specific inquiry into which the schools were led during the same period had respect to the forms of our understanding; how they are connected with or may be reconciled with those absolute truths, which seem to surpass our understandings, and yet, in some sense, to be meant for them.

The IXth
Century.

Transub-
stantiation.

Johannes
Erigena.

Berenga-
rius.

The IXth Century was a prophecy of all these conflicts. One great controversy which then came into existence may be said to contain and concentrate them all. Paschasius proclaimed the doctrine of transubstantiation. That sacrament which, in former ages, had been the witness and the embodying of a transcendent relation between men and their Creator, which by its very nature overreached the forms of human thought and expression, which was the perpetual declaration to men, that there is something that words cannot convey, was by this monk brought within the limits of a human conception. The high language of the Fathers, language intended to indicate the glory of a mystery which the understanding could not comprehend, was used to defend this dogma of the understanding; men were required to reduce their faith under the laws of their understandings, and then to call the acknowledgment of a transgression of those laws by the name of Faith. Assuredly the whole puzzle and contradiction of the time lay here. The germ of all political, personal, and scholastic confusions must have been in the century which produced Paschasius. Still it was only the germ. *Johannes Erigena*, the friend of Alfred, was invited by Charles the Bald to confute Paschasius, and he entered upon the task without fear, and for a long time without reproach. This great and accomplished man seems to occupy a position between the two ages of the world, to be the porch or vestibule of the schools, and yet to possess far more the spirit of the Fathers. He aspires to divide and arrange nature, to find out names for things; so far he is a schoolman. But his thoughts are Platonic—God is the beginning and end of all things. If, as has been thought, there is in his writings a latent tendency (of which he himself may have been unconscious) towards Pantheism, this may be an indication that the time for such large speculations was at an end, and that Johannes, though he escaped the errors of the time on which he was entering, was in some danger of those which belonged more properly to his predecessors.

But soon the character of the time became more determinate. The doctrine of Johannes was pronounced heretical; that of Paschasius was confirmed by Pontifical authority. The interesting and melancholy story of Berengarius, of his bold proclamations and defiances, of his retractations and humiliations, marks the new stage of feeling. The Pope did but utter forth the feeling of the time. His decree did but show that a dogmatical spirit had taken possession of the church, and that the perception of truths which could not be included in dogmas was daily becoming more difficult. But though difficult it was not impossible; and in this case, as in all other cases, it was through men who were brought into

contact with actual life, and were taught that philosophy either means nothing, or shows the way to truths which are good for others besides philosophers, that the tone of thought was raised. The struggles of high-minded priests in particular countries, in ours especially, against the tyranny of soldier monarchs, brought forth a sense of reality in their minds which raised them practically above the dogmatism of Paschasius, though they might not like Berengarius set themselves formally in opposition to it. *Anselm* was a man of this kind. His scholastic life was sustained by a political life, aiming at the same high ends, and calling for even greater sacrifices. Still more happily there were in his heart the deepest reverence and humility. His works, therefore, had all a real object, and turned upon questions which were occupying the church at large, at least as much as the schools; and they aim at distinguishing much more than at dogmatizing. Yet in them the scholastic habit discovers itself most clearly. Not to substitute understanding for faith, but at least to show how the understanding recognises that which faith receives, is his avowed object everywhere. Some of the great perplexities of the understanding, some of the logical meshes in which it afterwards became involved, he was ignorant of. But what he knew he sought to remove, perceiving with remarkable clearness that a different office was committed to the men of his age from that which had been committed to the Fathers, and yet that the two duties were harmonious, and that reverence for the past was a great help in fulfilling the work of the present.

It is generally understood that *Gregory VII.* felt very differently from his predecessors respecting the Berengarian controversy. It would seem that he not only loved Berenger as a man, but had a great sympathy with his opinions, and an honest dread of fixing the living words of Scripture into the dogma of transubstantiation. Such feelings would be perfectly consistent with the mind and character of this singular man. He evidently felt that the Bishop of Rome had a higher vocation than to dogmatize; that he was to assert the position of the church as an universal kingdom—real as any of the kingdoms of the earth, the only protectress both of invisible truths and of poor men's rights from royal and military ignorance and oppression. He was naturally disposed therefore to be impatient of those who would make him a mere censurer of opinions, and to have a respect for men of free and lofty courage like his own, who would break through logical fetters, and assert principles in their breadth and simplicity. Nevertheless it was the grievous error of this prelate, that he saw no way of claiming that position for the church which he felt was its right, except by inventing a title and dignity for himself which did not belong to him, and could only be maintained by attacking the rights and outraging the conscience of every national monarch in Europe. This was his falsehood, one which the sin of every previous bishop of Rome who had been asserting an unlawful pre-eminence over other bishops, or who had forgotten his glory as a servant in aspiring to be a master, helped to foster and sanctify; a falsehood closely connected in Hildebrand with high conceptions and great virtues, but which, being a falsehood, necessarily brought after it a long train of miseries. That which we have to speak of, was the growth and confirmation of that confusion of dogmas or decrees with permanent truths, which, as we believe, Gregory

Moral and

Century.

Moral and
Metaphy-
sical Phi-
losophy.

desired to discourage. The Pope having assumed the functions of an ordinary king or lawgiver, it inevitably came to pass that his laws were looked upon as the same in kind with those of any other monarch. The sense of a distinction between the great principles of which the church was witness, and the mere decrees which are enforced by civil authority, a distinction weakly upheld by former Popes, was now every day more and more obliterated; and hence confusions infinite and seemingly inextricable—in the World between the relations of the national monarch, and of him who assumed to be the universal monarch—in men's Hearts between the unchangeable laws of morality, and the different means which were suggested to enforce them—in the Schools between the realities of things and the names by which those things are generalized in our understanding. *Διός δ' ἐτελέετο βούλη;* through all these perplexities, clear distinctions were working themselves out; it was needful that men should learn in this way the nature of their political position, the grounds of personal righteousness, the forms and limitations of their own minds.

Realism
and No-
minalism
how con-
nected
with Plato
and Aris-
totle.

In noticing the philosophies of Plato and Aristotle, we have already distinguished between a science of realities and a science of names. We maintained that both were necessary; that Aristotle had no right to deny the principles of Plato which related to the one, that Platonists were not bound to deny the worth of Aristotle's positions which had reference to the other. At the same time we guarded against the notion that the Academic and Peripatetic doctrines could be reconciled, as Cicero tried to reconcile them, by saying that the difference was in words merely. We contended that the difference was an essential difference; that the minds of the two great teachers were of a directly opposite character; that whenever they attempted to deal with the same questions, they inevitably came into collision; that it was only by assigning to them distinct provinces, that we could recognise a sound meaning in each. Looking upon them as the originators of two great methods of thought, we deemed it needful to explain with greater minuteness than may seem suitable to such a sketch as this, what these two sciences are; showing how the science of realities developed itself in the different Dialogues of Plato, but most completely and consummately in the *Republic*; how the nominal science developed itself in the logical treatises of Aristotle, but most perfectly in his *Metaphysics*. We promised our readers that if they would be at the pains of following us in this portion of our discourse, they would be saved many troublesome and embarrassing explanations when they reached the portion of it at which we are now arrived. We have not therefore now to tell them what we mean by the words Nominalism and Realism. We have only briefly to explain how the sense of the opposition between them began to be felt in the middle ages. A translation of the *Organon* of Aristotle had been in the western schools since the time of Charlemagne. Such a book, so clear, coherent, and masterly, might well produce an effect on any age, by however much of other literature it was surrounded. But suppose it introduced at a period when men were drawn by various impulses such as we have described to turn their thoughts inwards upon the operations of their own minds—into nations possessing indeed some of the treasures of old Latin literature, but not having yet a history of their own to interpret them by, possessing also the inspired volume, but partly through

the same cause, partly through the dogmatic spirit which had taken hold of the rulers of the church, forced to look at it rather as a collection of sacred and important opinions, than as the free record of a divine revelation, and of a national life—and one can easily conceive how immensely precious *this* deposit must have seemed, how completely a gift of heaven, by which all other possessions were to be measured and appreciated. Such a sudden discovery to men of the modes and conditions of their own minds, such a strange revelation of the very thing which they were seeking to know! We have seen, however, how strong the old Platonic feeling, which had descended from the first period of the church, still was. The ideas of Being and Unity, the grand ideas of the Platonic philosophy, had become inseparably intertwined with the Christian mysteries. For, as we have observed, these ideas demanded some living personal mysteries to sustain them, and those which Plotinus and his school devised had been found inefficient and worthless. In teaching, therefore, the new science of Logic, the science which they learnt from the *Organon*, the school doctors still applied the principles of Plato. To these great universal ideas of Being and Unity, they attributed reality. Quite ignorant of the Platonic method, quite ignorant of the battles Plato had had to fight with Parmenides and his school, in order that the name or notion of being might not be substituted for Being itself, they taught it as a part of the science of logic, *the science of names and notions*, that universals have a life and reality of their own. Against this notion, Roscelin of Compiègne was apparently the first to protest. He had read an introduction to the *Organon* by Porphyry, in which the difference between the Peripatetics and Academics upon this subject of universals was pointed out. The truth of the Aristotelian doctrine came strongly home to his mind, and he began to assert strongly that Being and Unity are only the Attributes of substances, not Substances in themselves. But the ideas which these words represented had become united with the transcendent Truths of the Christian faith. It was a very difficult thing for any man so to sever them, that the denial of the one should not even in his own mind lead on to the denial of the other. It is very true that the logicians on the other side, just in so far forth as they were mere logicians, *implicitly* denied these realities. Still the *explicit* denial of them, or such a mode of expression respecting them as seemed to rob them of all meaning and substance, was reserved for the Nominalist. Happily Roscelin had a better opponent than any mere school doctor: Anselm, who, we have seen, had been bred in another age, and represented a different class of realists from the realists of the schools, undertook the controversy. But with the caution and charity befitting so good and great a man, while he replies to those statements respecting the Trinity which he had heard attributed to Roscelin, he carefully suggests a doubt whether this was actually his meaning; he fully allows the possibility of his having been betrayed into unfitting and inconsistent language, without really having a wrong intention; and he is only careful to clear from the confusions of philosophers a principle which he believes needful for every humble man.

It has been a subject of considerable controversy, Abelard, whether the celebrated successor of Roscelin in the Nominalist school, *Abelard*, was justly exposed to the same imputation of heresy with him. Without venturing to express any opinion upon this point, we may be

permitted to warn our readers against being misled by hasty and dogmatical assertions on either side of the question. A thorough study of Abelard's philosophy (from which it would be by no means right to separate the romance of his life) would no doubt contribute very much to an illustration of all the topics connected with this memorable and interesting controversy. But vehement phrases, either imputing an intention to him of entering upon the theological ground, when he may have meant, if it had been possible, only to assert a logical position, or on the other hand, railing against those who opposed him as men of a savage turn of mind, enemies of freedom of thought, bigots, and zealots, can do little good, except to perplex our view of the history, and make the steady contemplation of its different aspects impossible. It is absurd to say that St. Bernard, the great antagonist of Abelard, excelled him only in his declamatory power, and in his orthodoxy. He was superior to him in every quality of heart and head, except merely in the logical faculty. He was by constitution, by principle, by habit, a Realist in the practical sense of the word—not skilled perhaps in the language of the schools, but what is better, able to sweep it away where it set itself in opposition to any great truth which belongs to mankind, or to any effort for its good. And it was this realist spirit, the spirit which prompted the Crusades as the outward act of the united church, and all zealous individual labours after a higher standard of life and excellence, which really held back the nominalism of the schools, and caused Aristotle for a time to be a proscribed name. The Popes saw that the *Organum* had produced a result which at least looked like heresy; and they had themselves abetted the confusion which made it difficult for men to distinguish, even in their own minds, between the denial of a substantial verity and of an imaginary abstraction. Still the spirit of inquiry continued. Some maintained the logical ground, following in the train of Roscelin or Abelard, or of their opponents. Some, weary of these conflicts, ascended to a higher level, and strengthening the piety and wisdom of Anselm with the dialectical skill which had been acquired in the late controversies, applied themselves to the practical study and elucidation of Christian theology. Hugo de St. Victore is the most conspicuous and best known of these, the one whom his contemporaries honoured with the name of the second Augustine. Another light of the XIIth Century was Peter the Lombard, who collected a series of propositions and questions from the Fathers, offering them without solutions of his own to the study and ingenuity of his contemporaries. His work had a great influence on the two centuries which followed.

Aristotle, we said, was proscribed by the ruling power of the church, and regarded with jealousy by some of its best members. But it was not in the power of decrees to change the character of a period; men exhibited that character in themselves, even while they opposed themselves to the outward indications of it. St. Bernard as much as Abelard belonged to a time in which thinkers were occupied with their own internal struggles primarily, and only with questions more strictly divine and transcendent in the second place. The disposition to organize, to form a rule and plan of life, to invent an order rather than to perceive one, were eminently characteristic of him, and of all good as well as evil men in this day. Now these are, as we explained when we were speaking of Aristotle, the marks of his

mind as distinguished from that of his master. In his Physics and Ethics, nay even in his Politics, we found him studying the forms of the mind itself, rather than entering into the contemplation of its objects. We found in him everywhere a tendency to arrange and systematize, to form a plan where Plato sought to discover a method. There was then a natural sympathy between this philosopher and the ages we are speaking of, which had already manifested itself very decidedly, and which was quite sure to prevail at last in spite of all opposition. Hitherto the *Organum* had been the only one of his works with which the schools had been acquainted, even through a translation. Now a new light was to break in from a strange quarter. During the time in which the mind of western Europe had been gradually forming itself under the influence of Christianity, the mind of the Arabian had also been awakened to reflection. The conquering nation, as it came into regions which Greek philosophy had occupied, found some link between what it heard of this philosophy and the deeper principles of the Koran. In Neoplatonism there were abundant points of resemblance with that idea of Oneness and Absoluteness which had driven out all others in the Mahometan system. With this form of speculation, therefore, their thoughtful men acknowledged an immediate sympathy, and the habit of mind, with the series of reflections thus generated, became the most permanently characteristic of the nation. Through the Neoplatonists, however, the Arabs became also acquainted with Aristotle, and the new world of observations respecting every part of outward nature which burst upon them through his writings seems to have inspired this people with an astonishment and admiration hardly second to that which the young Romans felt when they first discovered what men had been thinking and talking of for so many centuries in Athens. Here too there were points of sympathy with old Arabian habits, with the astrological studies to which their fathers had been devoted, and with that mathematical faculty which seems to be an Oriental endowment. The love of Aristotle, and the general impulse to cultivation among this people being favoured by a race of accomplished monarchs, translations and commentaries upon him became more and more numerous, and sects of philosophy began to appear connecting themselves more or less with the national faith, mingling more or less of the mystical feeling which was so remote from the character of Aristotle, but still all deriving their sanction from his name. It is natural to ascribe the importation of this feeling and knowledge into Europe to the Crusades. But the difficulty of course remains how to account for Arab translations and commentaries becoming effectual upon the Latin schools. The generally admitted explanation is curious and interesting. It was through Jews, the oldest teachers of the world, now its merchants, that the ruling philosophy of the middle ages was enabled to establish itself. A strong philosophical impulse had been felt among them also. Their teachers, in Spain especially, were most laborious in translating and explaining Aristotle, and the writings of the Greek philosopher passed first into Arabic, then into Hebrew, before they became in a Latin dress the guides of men's speculations for at least two centuries.

There are many circumstances which may suggest the opinion, that it was the character of Aristotle's ethical treatises which determined the judgment of the age and the church in his favour, and relieved his name from

the stigma which the supposed heresy of Roscelin and Abelard had brought upon it. We have seen how certain habits or forms of character were Aristotle's substitutes for the absolute and real objects which Plato sets before us. Now it may be truly said, that the superstition of this age consisted in its tendency to deify certain forms of character, certain conceptions of the fancy, or certain modes of the intellect, and that its excellence and virtue was closely intertwined with this same superstition. The same circumstances which brought Aristotle's works into Europe, gave the great impulse to the spirit of chivalry, to the pursuit and worship that is of a noble idea, of an idea most important and necessary to man, but altogether incomplete, and being incomplete, obliged to connect itself with transitory circumstances, and to lean upon the reverence for a single class of society. These habits of mind, which, though brought into outward display by mailed warriors, dwelt also in the cell of the student, must have made Aristotle's brilliant pictures of the Magnanimous man, the Temperate man, the Gentle man, particularly delightful. His works must have been felt to be in some remarkable manner a prophecy of that Christian age. Nor was this the only point of attraction and sympathy. The growth of chivalry was not a more remarkable characteristic of the XIIIth Century, than the rise of the religious orders. As the purpose for which the church existed became less manifest, the notion of new religious bodies, and new schemes of discipline, began to act more strongly upon men's minds. In such bodies the grand ecclesiastical idea, that the end of our lives is the knowledge of God, is soon effaced, except in a few chosen spirits, by the doctrine, that the object of our lives is to attain happiness here or hereafter. With this doctrine that announced by Aristotle wonderfully accords. Moreover, the tone of his morality is peculiarly favourable to the notion, that a scheme of discipline is the great requisite for human life. The formation of habits is to be attained, he taught, by the constant observance of the influences which may incline us too much to the right or to the left; means in his system have a continual tendency to become ends. The earnest preachers of a new rule of life must have found such doctrines remarkably congenial to their minds, even if there had not been enough to fascinate them in Aristotle's love of systems partly at least arbitrary. The influence of the Franciscans and Dominicans, now the strongest and the most earnest which was at work, was therefore exerted energetically in his favour. It soon secured the prevalence and success of his whole philosophy. But there was also another part of his writings which took mighty hold of the Christian as it had of the Arabian schools. It was one of the happy circumstances in the development of modern Europe, that the zeal for physical inquiries which was the first excited in Greece, and which overlaid all others in India, did not arise till men had already been occupied with questions more nearly concerning themselves. Our almost countryman, Johannes Erigena, had indeed exhibited an inclination towards a class of studies which we may truly call national; but the spirit was checked, and did not reappear in any strength till four centuries after. Then arose another and perhaps greater Briton, the "Doctor Mirabilis," Roger Bacon, and mathematics, chemistry, and physics generally became as much the studies of Christians as they had already been of the Mahometans. In him we have the philosopher of experiment under

whatever disadvantages and ignorance it might be pursued; the opposing or balancing mind to his was Raymond Lully, the student of the secret powers of nature, the originator of the *Ars Magna*. But this impulse, whichever of these directions it might take, still found its great help and encouragement in the writings of Aristotle, and the books on the Heaven and the World, with the Natural History, were some of the first of those attributed to him which were studied and commented on.

These Ethics and Physics furnished then a new material for the mind of the age to work upon; and the opposition of those who cultivated exclusively the first to the laborious students of the other, illustrated in the imprisonment of Roger Bacon by Franciscan influence, forms one of its indications. But we have discovered already in the history of Greece, and above all in the writings of Aristotle, at how many points both moral and physical studies abut upon that to which he first gave the name of *metaphysical*. We have seen, in fact, that the meaning of that world only becomes intelligible when we consider it in its relations to other subjects, and again that Aristotle himself could not contemplate it apart from Theology. It cannot be surprising then that of all the writings of Aristotle, those which exercised really the most influence, and which became the interpreters of the rest, were the Ontological treatises. As we have given our readers an account of those books, both as to their matter and their form, we need hardly remark what a vast body of questions they must have suggested to the minds of men at all prepared for them by any previous discipline. Now Peter the Lombard had set the schools upon the questioning method. He had proposed, as we observed, a number of difficult points taken from the writings of the Fathers expressly for consideration and resolution. Such a hint once given, and being met by the new gift of Aristotle's metaphysics, was the exciting occasion of those mighty masses of ontological and theological puzzles and argumentations which constitute what is called "the jargon of the schools," by those who can tolerate nothing but the jargon of the world.

Albertus Magnus was the person who first appears to have availed himself of the new resources for the purpose of forming a complete system in which Metaphysics or Ontology was the key to the other portions. We have seen how the ideas of Form and Matter, the one as that which constitutes every substance what it is, the other as its condition and *sine quâ non*, lay at the foundation of the metaphysics of Aristotle, and determined his thoughts upon every other subject. We remarked how closely these ideas were connected with logic, so that the fact of any thing being capable of definition is with him the test of its having a form and being a substance. While, therefore, we admitted the great value and importance of this Aristotelian distinction, we could admit it only as a distinction in and for the mind. For the moment it becomes more than this, we get upon the Platonic ground which Aristotle believed to be merely imaginary. His forms become the ideas of Plato, and these ideas derive their meaning from the reality of one who is himself *THE BEING*, not merely a particular form, though it be the highest form, of being. Now the philosophy of Albertus, and of those who succeeded him, is, we conceive, subject to precisely the same criticism as that from which it is derived. If we want help in determining the conditions of our own mind, our own modes of

Albertus
Magnus.

Moral and
Metaphy-
sical Phi-
losophy.

thinking in relation to all subjects, we suspect that we can obtain it nowhere so well as from these schoolmen. And seeing that the whole subject of Christian theology, with all the lights which it throws upon other subjects, came under their notice, they clearly had an opportunity which it would be wrong to say that they neglected or abused, of applying the Aristotelian observations in a direction entirely new. At the same time they, as much as those who knew nothing but the *Organum*, were dealing simply with forms and notions of our mind; they were not really theologians, physicians, or metaphysicians, they only explain under what terms theology, physics, metaphysics, are conceived by our understandings.

Bonaventura.

This statement must be taken in a general sense, and not by any means as if it were meant to deny that most valuable hints respecting substantial truths, as well as respecting our conceptions of them, may be obtained from these writers. It is impossible that they could follow out their own course steadily and honestly without throwing light upon all that was delivered to them by a former age, or was to be the occupation of a subsequent one. Still less is it intended to insinuate that a mere intellectual theology expelled in this age spiritual meditations. Such a charge would be false respecting many teachers of the XIIIth Century; it would be especially inapplicable to Bonaventura, the seraphic doctor, whose great object was to teach how the soul might be united to God, and how the light which is contained in all arts comes from the primary light whereby He is revealed to men. Even in these spiritual and seraphic doctors, however, there was a tendency to contemplate all things as reduced under Subjects and Systems; and in them as well as in the Mystics who rose up a century later and were some of the instruments in undermining scholasticism, self-contemplation is still at the root, and the highest objects are viewed in their action and influence upon the beholder.

Thomas Aquinas.

The man who reduced these habits of thought into the most perfect order—who carried them into every region of study—who has always been recognised as emphatically *the* Schoolman, was Thomas Aquinas. Bonaventura had conceived the possibility of reducing all arts under theology. Aquinas may be said to have actually reduced them. If one man can ever be supposed capable of conceiving all possible forms of human thought, all possible difficulties which can be put into a logical shape, that man was unquestionably Aquinas. No one who looks into his writings can wonder that they should have been the text-book of philosophy and theology for generations. It is idle to say they became so, merely because they settled questions according to the decrees of the church. No one, probably, ever awakened so much scepticism of the logical kind as he; no one, apparently, had a more conscientious mind; no one was more unwilling to adopt a conclusion till he had thoroughly sifted it. If there were no puzzles in the mind but dialectical puzzles, or if those puzzles did not require something deeper than dialectics for their solution, Aquinas ought still to be our guide. But school philosophy itself was to furnish the hint, that they do require something else. A countryman of ours, Duns Scotus, discovered that there was one great blank in the system of Aquinas, perfect and circular as it seemed. We want, said he, a principle of individualization. We want to know, not merely how all things conspire to form one great whole, but how each

Duns Scotus.

thing becomes that very thing distinct from all others. Such, we take it, was the idea which was working in the mind of Duns Scotus; the thought which he was labouring to bring forth, and which did make itself felt as an important thought by a body of earnest disciples. By many of his assertions he seemed to be contending for a more realistic doctrine than that of Aquinas; to be condemning him for not imputing more substance to universals. But this, it seems to us, was a subordinate and accidental part of their differences; the other radical and characteristic. To us the contemplation of this difference is most interesting, for it illustrates an observation we have made before, that the scholastic philosophy was not, as some fancy, a thing wholly unconnected with real wants and controversies, but was only a private rehearsal of that which was acted openly on the great stage of society. The Thomists and the Scotists are but school types or images of that great battle between the universal and the individual, the united and the distinct, which was just at that time beginning to be the great battle of the world, and of the parties in which Italy and England were to be respectively the heads. The Neapolitan and the Northumbrian were well fitted to be the symbols of their two countries and avant-couriers of much that was about to happen in them. In both alike the age of Towns was beginning. But the splendid Cities of Italy were to form aristocratical Republics, the temporary deposits of a national spirit which was soon to subside in the universal government of the Church. The Towns of England were to be the cradles of a middle class; the great rival power to the aristocracy, the great helper to the national monarch in asserting his own position. Other indications were connected with these, more directly affecting the popular and the scholastic life in each country. In each a clear, orderly, native language began to manifest itself—the southern preserving more distinctly the traces of its Latin father, the northern of its Teutonic mother. The one language came forth in its fulness and power to be the utterance of Dante's wailings; the other to be the tongue of Wickliff's Bible. Theology was the material of the poem as well as the translation; but in one case it was the creative power availing itself of all the theological ideas of the age to express its sense of contradiction and evil; in the other it was the burdened conscience of man seeking to find some better interpreter of its wants and miseries than those ideas, imprisoned in their logical forms or exhibited in arbitrary inventions and impositions, could afford. The theological poetry of Dante, therefore, though opposing itself so fiercely to some of the corruptions of the times, and launching such thunders against some of the successors of St. Peter, was not to awaken, except in some few minds, any ardent longing for reformation. It is to be rather regarded as the first vehement utterance of a Spirit which soon found Painting a more suitable language than Poetry, and which sought to embody the mind and feelings of the church rather than to change them. But the individualizing principle, the sense that is of each man's own distinct wants and distinct evil which had appeared in England, and of which the acts of Wickliff and his followers were the expression, could not be satisfied with the formal recognition of its existence which Duns Scotus had vouchsafed. This principle, translated out of the Latin into the new English, meant the living soul of each man; and this could not be content till it had been acknowledged as

Moral and Metaphysical Philosophy. an integral element in the being of the church, and till it had swept away every dialectical conception or authorized dogma which stood in its way.

The XIVth Century. The XIVth Century, therefore, which had been already exposed to these influences, and in which they were daily becoming more powerful, soon gave a shock to the school systems, whether they bore the name of

Occam. Scotus or Aquinas. A pupil of Scotus, William Occam, also an Englishman, began early in this century to reassert the nominalist doctrine of Abelard, with all the advantages which were derived from the information and experience of his age. Abelard had stood forth as the champion of Aristotle against Platonism. Aristotle was now a canonized dictator in the schools, and it was that very dictation which the nominalism of Occam was to subvert. For though in teaching that species and genera are only abstractions of our minds, that they had no entities corresponding to them, he might seem to be asserting the very doctrine of Aristotle, that substance is only predicable of each particular thing; yet Aristotle had in effect applied these forms of the understanding to the contemplation of every possible subject; and the schoolmen, his successors, had, as we have seen, carried those forms into regions to which Aristotle had no access. Whether the nominalism of Occam led him to scepticism about the articles of faith is a question of perhaps less difficult solution than that which relates to Abelard. His language being directed against forms which had worked themselves into union with every great mystery, must of course have at times an irreverent and sceptical appearance; but he seems to have recognised distinctly all the Christian truths as matters of faith, though he questioned the attempts of the understanding to deal with them. In another way he occupied a position singularly characteristic of the coming period. Though an ecclesiastic, he maintained the national rights of the French sovereign against the Pope. Now, as Occam may be regarded as the last philosopher of this age, as the one who in a certain sense wound up its history, (for from his day forth nominalism had decidedly the ascendancy, and no very strong man arose to maintain that logical formulas are real objects,) it may seem at first a melancholy reflection to compare him with Anselm, who arose at the commencement of it. One might be tempted to think that, exactly the thing which he essayed to do, to connect namely the faith of man with his understanding, had been, after so many centuries, found impracticable, and that the corresponding labour of his life, to maintain the principle of the universal kingdom in opposition to the tyranny of national monarchs, had been in like manner abandoned by wise ecclesiastics as unreasonable; nay, that precisely the opposite vocation, that of supporting national government, had now become that which they laboured to fulfil. These two reflections, which cannot well be separated from each other, are likely, we say, to present themselves to the student of this age, and there is some warrant for the melancholy feeling which they engender. Undoubtedly the understanding and faith of men had not been reconciled by the efforts of all the schoolmen; nay, the schism between them had now become wider than in the days of Anselm. Undoubtedly, also, the ecclesiastical government, instead of being hailed now as the protector of the weak against the strong, of the invisible against the visible, began to be regarded as the great instrument of oppression, as the power by which men were held down in a visible

bondage. So far the contemplation is gloomy. It seems as if nothing had been accomplished in this period, as if it had been one of degeneracy, not of progress. But if we look again, we shall see cause to abate these lamentations; nay, to exchange them for the language of thankfulness and hope. Through terrible conflicts, in spite of fearful sins, this age had been really effecting its work, and was to leave imperishable tokens for the generations to come. The first period after Christianity had left the form of a universal polity; had left ordinances, creeds, ecclesiastical institutions, the witnesses of this universal polity, the powers by which it was upheld, and by which men were enabled to possess and enjoy its benefits; it had left records of the oppositions through which transcendent and universal truths had been maintained and confirmed; it had left a literature connecting itself with the former literature of the world, and showing that what therein had been foretold or wished for had come to pass. If these deposits remained and remain to this day, is it not equally true that those middle ages have left their deposits? National societies grown up from infancy to manhood; the forms of law established; languages created and defined, new forms invented in which the conceptions of men could clothe themselves—forms of architecture, of poetry, and finally, of painting; last, and we are bound to say not least, the full power and dimensions of the logical faculty in man ascertained by a series of precious experiments determining what it can and what it cannot achieve. For let no one say, that the scholastic philosophy is obsolete in its effects, because the volumes which contain it are seldom read, and because it has been found to have failed in much that it hoped to do. Not the feeblest newspaper scribe, who writes praises of the XIXth Century, and talks about the discoveries of Bacon, and the vain squabbles by which men were distracted till his time, could cast even these empty phrases into a coherent and intelligible shape, if those schoolmen whom he abuses had not lived. As truly as we owe our laws and ecclesiastical buildings to the middle ages, so truly do we owe to them our forms of thought and language. We are very unhappy if we have not learnt much since that time, and we shall presently have to show in what direction that learning has been won. But in fixing the terms and conditions of human thought, we are bold to say, that men have only done any thing by going back to these schoolmen, and using the fresh light that may have fallen upon us to the more effectual consideration of the questions which they raised.

When one reflects on these facts, men may surely be well content, that what is called the revival of letters came when it did, and not four or five centuries earlier. Most sad would it have been for the world, if the western nations, instead of being left to work out a cultivation for themselves with only such helps from ancient lore as best suited the thoughts which were awakening in them, had been overlaid with heaps of books, in which their circumstances gave them no interest, which they could not interpret livingly, and which would therefore have crushed all sparks of native and original speculation. When that revival did come, the inhabitants of western Europe were in some way prepared for it—prepared at least, by their own sense of a national position, to enter into the national feelings, and the thoughts and inquiries accompanying them, whereof Grecian books are the exposition. But they were not prepared for the glare of new light bursting upon eyes long

mation.

used to turn only inwards; a sense of confusion mingled with their delight at the novel world of action which was opened to them; they knew not how to connect it with any thing that they had been taught to think of or believe; that belief became therefore daily less and less sound and sincere. Meantime a new order was rising into consequence, which had little sympathy in the old traditional feelings, nay which had been for a long time contending against them. The scholars of Europe disliked this class and its feelings; they would keep up the old forms and opinions to which they had ceased to attach any meaning, lest the unlettered men should prevail. These forms and opinions, used with this ignorance of their nature, this conscious indifference, would of course become more and more corrupted—the convenience of repressing by the sanctions of religion that which could not otherwise be kept down, suggesting new expedients, and no reverence for the sanctity of the thing to be profaned hindering the adoption of them. Nor was it difficult to make these impostures successful. For that which was most alive in those who composed the new class was the Conscience. The deep sense of internal evil, the feeling of a condemning law, which had connected itself closely with the whole theology of the middle ages, might be almost extinct in the lettered priests of the hierarchy, but had become deeper than ever in the minds of humbler men—deeper because, having broken loose from the forms and questionings of the schools, they were transferred to the region of each man's personal being. Having reached that point, these feelings could no longer be tampered with. All the old power and the new wisdom of Europe might be on one side, but reality was on the other. In such a conflict the learning of Leo, the policy and greatness of Charles, the physical forces, nay the moral forces of old habit and tradition which they had at their command, could not prevail, for that which alone gives life to all these was wanting. Yet, though it was a new class which was to assert its position in this struggle, though it seemed at first sight to be breaking through all established bounds, and to be removing ancient landmarks, it was really an old feeling that was coming forth, a feeling belonging to that which is permanent and eternal, and claiming that which was permanent and eternal to rest upon. It was not to maintain the powers of the understanding that Luther stood forth, but to declare the might of faith; not to dispute old creeds, but to claim them as the witnesses of a personal Being, and of man's connection with him; not to teach that the feeling of separation from this Being of which past divines and schoolmen had spoken, meant nothing but that it meant every thing; not to say that the sacraments which had been the possession of the Church for fifteen centuries had lost their power, but that they were the sure witnesses of man's reconciliation, and that only by accepting them as such could the burdened conscience be delivered. In like manner, it was not by teaching men that the old literature of which they had lately become possessed signified nothing and that their only work was to forget the past, but it was by opening to them the history of God's past dealings with the world, and showing them how these concerned all their common and daily life, that the great Reformer prevailed. And therefore it may truly be said, that he seems to have been appointed more to explain the meaning of the period which we have been considering, to justify its toils, to make them effectual for good, than even to give the

character to that on which we shall presently enter. It had been an age of *Law*, in which nations had been brought under the yoke of fixed and positive government, and in which individuals had sought to shape out a rule of life for themselves. Luther showed what law has to do with man, how fixed, absolute, irreversible it is! how impossible it is to evade its sanctions, or to substitute any inventions of ours in place of it! how the conscience of man answers to its decrees! It had been an age of discussions about Ontology, about Realities, and Names. And Luther's declaration of a personal being, in whom men might trust, and by trusting in whom they might be delivered from personal transgressions, was the practical Realism which satisfied the heart of man, which connected itself with the former questions about law, but left the understanding to pursue its own way in dealing with the names of things. It had been an age in which men had glorified certain human qualities, making these their ideals of human excellence, though they could only be attained by the members of one class, and needed outward ornaments to recommend them. He brought out the truth, that there is a perfect humanity for each man to behold and to claim as his own, a humanity in doing homage to which he does not worship himself, but God,—a humanity set forth in one who had entered into the feelings and the sorrows of every peasant. It had been an age in which men had sought to discover how universals are connected with individualities, and Luther rose up to carry forward the assertion of Wickliff with clearer light, that there must be an universal body, but that unless it recognises the distinctness of each particular man, it does not fulfil its own conditions.

It is no doubt true, and the fact requires as much to be noticed by the historian of philosophy as by the theologian, that the side of this last truth which had been most kept out of view during the middle ages, was the side which now thrust itself forward at times to the utter exclusion of the other. By a portion of the Reformers the distinctness of the individual man was felt to be all in all, the idea of a fixed and permanent constitution was thought of only as subordinate to this; and though this was not the case with Luther, it is true that his position, as well as that of his brethren, prevented him from asserting as he would have wished that there is a catholic body, though it do not derive its catholicity from the sovereignty of a local bishop. But this circumstance only shows more clearly how completely the Reformation was the winding up of that particular discipline to which western Europe had been subjected since the days of Charlemagne. Universal truths, the idea of a universal commonwealth, it had been the work of the first period to bring forth into clear manifestation. The truths which concern each man's own life, the national order by which that life is realized, had been gradually working themselves out in this second time. The Reformation so far brought the two ages into harmony, for it showed that each man truly lives only when he has claimed a higher life than his own, that each nation truly lives only when it acknowledges direct allegiance of its monarch to an invisible King. More than this might be wanted. The continuance of a number of nations in subjection to the Romish Pontiff, the continued recognition at least by *one* (and that the one which we spoke of as the first and ablest assertor of the individual and the national principle) of its relation to the elder church, even while it resisted the usurpation to

which that church had been subjected, may prove that something was wanted which this crisis did not develop. What it was we may discover as we proceed. But this at least seems certain, that we have arrived at a very notable crisis in moral and metaphysical history, the effects of which upon the age which followed it we must now begin to trace.

From the Reformation to the French Revolution.

Effects of
the break-
ing up of
the Feudal
system.

When alluding in an early part of this sketch to the form of society which was established through Hebrew influence in Egypt, and tracing in it some likeness to the feudal system of modern Europe, we remarked that the root of that system lay in family relationships; though all its outward characteristics were connected with notions of military subordination. In this opinion we believe most writers on the subject substantially agree, though they may not adopt the same language. For though the old notion of discovering this system among the German tribes has given place to the much juster and more reasonable doctrine which makes modern institutions an outgrowth from the old institutions of Rome, no one can doubt that there was a plea for that notion, and that some modification of it is necessary in order to account for the difference between Teutonic and Roman life, even when both had been brought under the same Christian influences. And therefore all considerate persons have attached much importance to that reverence for marriage and for the bonds of family life generally, which characterised our German ancestors; these they have regarded as constituting a capacity for the reception of Roman order and law. This being admitted, there seems little difficulty in understanding that the time when that which is properly called the system of feudalism began to crumble, the time when its legal and formal restrictions were relaxed, and when another order appeared in the nation which had to work out a system of government for itself, may have been the time when the original *principles* of this system—its properly Teutonic elements, were brought out with a new strength and distinctness. Every one must feel that our landed tenures, with the principle of primogeniture lying at the basis of them all, did in some way bear a more decided witness for a family principle than any institutions in the old world with which they might be compared, or from which they had been derived. Yet so long as the aristocracy formed the nation, so long as all, however little related to them by any real ties of kinsmanship, were connected with them as military dependants, so long as there was no class witnessing for some other than this family principle, and thus making that better understood,—it is evident that the real meaning of these institutions must have been latent, not developed. Other circumstances connected with the history of this age assisted in keeping this meaning out of sight. The reverence which the church seemed to pay to the institution of marriage, by reckoning it among the sacraments, was no practical compensation for the slight which it put upon that institution, by refusing it to the most revered members of the commonwealth. The separation of a portion of this body, not only from this but from all the relations of life, tended still further to weaken the respect for them. Chivalry, by carrying men to the pursuit of distant objects, and an ideal of character, had the same tendency; so that the influences which most determined the character of the period, however favour-

able to some exercises of virtue, and especially to reverence and loyalty, were clearly not favourable to the homely and household graces. While chivalry was the indication of a deep and sincere feeling, while the inspiration which prompted the establishment of the religious orders was alive, the evil might be less felt. But when a fashion had succeeded to a faith, indulgence to discipline, men could not fail to observe how much the pretence of something that was higher destroyed all plain and practical morality. The feeling was likely to be strongest in the new class—that which was on other grounds discontented with the tone of feeling in the church, which did not share in the visions of the aristocracy, and which, being removed from the temptations of wealth and foreign intercourse, was likely to practise a simpler and purer habit of life. These circumstances alone might seem to account for the manner in which the Reformation operated to substitute reverence for relationships for that homage to some human ideal which had distinguished the middle ages, and that pursuit of absolute excellence which had characterised the Fathers of the church. But such circumstances would not have produced such an effect unless the theological character of the Reformation had been moulded in conformity with them. It was so moulded in a remarkable degree. That truth to which the conscience betook itself, when it was pursued by the fearful image of a condemning law, was the belief of a relationship, established between God and his creatures, expressed in the baptismal Covenant, to be realized by the faith of each person. As the Bible was more and more appealed to by the reformers against the logic of the schools, the idea of this divine relationship as the ground of all human relationships—to be set forth and realized in them—became more steadfastly present to their minds. Grasping this principle they became less concerned about the undermeanings which men of a former age had perceived or suspected in the sacred writings. The plain letter was seen to contain a deep mystery, and through that mystery to expound the scheme of practical life, and the different relations and conditions of that practical life became, to an extent which persons who have formed certain conceptions of the Reformation for themselves would not easily believe, the subjects treated of in the most earnest exhortations, and even in the higher divinity of the time. Thus two curious and somewhat paradoxical results came to pass. The middle class, the class which represented the individualizing feeling, preserved the family feeling of which the aristocracy is the proper representative, and, in the countries which submitted to the Reformation, enabled the aristocracy, divested of its military dignities and fiefs, to assume its true position. And the Reformation itself, while it seemed to be lifting men out of the grovelling notions and practices of the day into that feeling of connection with the invisible world, which formed the basis of the older and sublimer morality, did in fact give a more human and common-place direction to men's thoughts, causing that the cultivation and the study of these relationships should be the centre of the moral studies and moral inquiries of all those ages which were directly subject to its influence.

But we have seen that there is a Greek as well as a Jewish, a metaphysical as well as a moral side to human inquiries. A habit of estimating highly the family relationships was one effect of the Reformation, but it was not the only one. Another has been much more noticed, and should be certainly not passed over; the sense of

Power, of a power belonging to each man distinctly, and not to men acting merely as portions of a body. Those who teach that the powers of man woke at once from a deep slumber just at the beginning of the XVth Century, or somewhere in the course of the XIVth, do indeed use strange and preposterous language. For all the seven centuries during which the western people had been growing up these powers had been most wonderfully developing themselves. In the conflicts of political parties, in the conflicts of the schools, in splendid enterprises and lonely watchings, the human faculties had been acquiring a strength and an energy which no sudden revolution, if it were the most favourable which the imagination can dream of, ever could have imparted to them.

The
XVth
Century.

Vigorous
exercise of
the creative
faculty.

But it is true also, that the consciousness of these powers, the feeling that they were within, and must come out, was characteristic of the new age. They had been exerted before in ascertaining the conditions and limitations to which they were subject, exerted with the pleasure which always accompanies the feeling of duty, but not from a mere joyous irrepressible impulse. Set free from the bandages of logic, yet still with that sense of subjection to law which was derived from the logical age, exercised under the sense of a spiritual presence, without the cowardly dread of it; these faculties begun to assert themselves in the XVth Century with a gladness and freedom of which there was no previous, and perhaps there has been no subsequent example. In those countries which had effectually asserted a national position, and where theological controversies were so far settled, that they did not occupy the whole mind of thinking men, or require swords to settle them, this outburst of life and energy took especially the form of poetry. English poetry had from the first been connected with the feelings of Reformation and the rise of the new order; Chaucer and Wickliff expound each other. And now Protestantism manifestly gave the direction to the thoughts of those who exhibited least in their writings of its exclusive influence. The high feeling of an ideal of excellence which had descended from the former age, and which in that age had not been able to express itself in words, now came in to incorporate itself with the sense of a meaning and pregnancy in all the daily acts and common relations of life, and the union gave birth to dramas as completely embodying the genius of modern Europe, as those of Æschylus, Sophocles, and Aristophanes embody the genius of Greece. Throughout Europe the influence was felt. The peculiar genius of Cervantes did not hinder him from expressing the feeling which we have designated as characteristic of the time, only as was natural from his circumstances with more of an apparent opposition to the older form of thought. And he as well as Ariosto and Tasso were able to bring forth in their works the national spirit of their respective countries, just as Shakspeare, with all his universality, exhibits so strikingly the character and life of England.

How Aris-
totle and
Logic re-
gained a
portion of
the power
of which
the revival
of letters
and the
Reforma-

It is important to make these remarks, though they may seem foreign to our immediate subject, that we may understand the peculiar moral and metaphysical tendencies of the time on which we are entering. As yet those tendencies displayed themselves far more remarkably in the creative works of which we have spoken, and in theology, than in what are strictly called philosophical speculations. How closely these had identified themselves with theology in ancient Greece as much as

in Christendom, we have had continual occasion to observe. It was not likely that they would be severed now. The time probably when philosophy made most effort to establish itself on a ground of its own, was in the period immediately following the revival of letters, and preceding the Reformation. Then that habit of unbelief, which we saw everywhere growing up, especially in the cultivated classes, together with the impatience of scholastic fetters, drove men to seek among the sects of Greek philosophy which arose in the sceptical age, for amusement or sympathy. The new kind of practical doubts, far inferior in real depth to the doubts of the schools but more plausible and attractive which the history of ancient speculation supplied, took hold of superficial minds, and the Aristotelian forms were not found sufficient to subdue them. Then there arose up men of earnest and deep minds, such men as Picus of Mirandula and Ficinus, to revive the old Platonic ideas, and to show what witness they bore for those truths which men were ready to abandon. But the Reformation terminated this kind of controversy, or made it unimportant, by bringing real human interests into play, and connecting them with the direct facts of Christianity. Hereby, however, a new and unexpected result was produced. The reformers had been assertors of faith against logic, of the realities of the Bible against the formalities of the schools. But when they began to argue and to teach, they found that they too had need of the school wisdom. They found it impossible to distinguish false statements from true, to possess in any sense a theological nomenclature without resorting to Aristotle and his disciples. We have explained why it must have been impossible. Aristotle is emphatically the teacher of names; the ascertainment of the distinctions and boundaries—of the necessary forms and conditions—of the human intellect. The schoolmen did but show how questions relating to theology, and to every other subject with which they dealt, must be expressed according to these forms. In setting out a scheme of thoughts, either for controversy or instruction, it was not a matter of choice, but of necessity, that these forms should be adopted. There were no others; to be unscholastic in things pertaining to the schools, you must be incoherent and irrational. The main question now as heretofore was, how the scholastic forms and the realities which men had fled to as a refuge from their tyranny could live and dwell in harmony together. That they must coexist under some condition or other was certain; the history of modern Europe had demonstrated it. And that there would be some providential scheme for redressing the evils arising from the prevalence of either, was also to be expected, and has, we think, been proved by the different outbursts of religious feeling, for a time resisting all forms, and then subsiding into great formality in most of the nations. Whether there were any healthier and better means of reconciling that which is properly human, universal, and real, with that which is definite, scholastic, nominal, those utterances of actual wants which belong to man himself, with the distinctions which are needful for those who are to be teachers of others, or who are subjected to an intellectual discipline; and whether, if there be such an expedient, any nation has hit upon it—is a question which we shall not discuss here. Our object is to show how Aristotle, after being in a manner denounced by the reformers, was at last inevitably taken into their favour again; a circumstance not merely

affecting theology, but all other studies, and the progress of human inquiries generally.

The form of theological and philosophical questions in the first century after the Reformation was then derived from the previous age. It might also be said, that the questions themselves were not new. They had all been debated again and again in the schools. For instance, of the two great theological controversies, that relating to the Eucharist, and that to the decrees of God and their relation to the will of man, the first, as we have seen, began with the beginning of the scholastic age, and the latter had certainly been a topic for meditation in every part of it. But these controversies derived such a new character from the Reformation, that though they occupied men so much before, they became new and the signs of a new era. The sacramental question in the former age turned upon the attempt to reconcile the forms of our understanding with the need which we feel of admission into a region which is above our understanding. And this might, for a time, seem to be the difficulty of the reformers as much as of their predecessors. But if we look deeper we shall find that the feeling of a direct relationship established between the Creator and his creatures, a feeling not now surely for the first time realized but now for the first time occupying the central place in the thoughts of Christian men and Christian students, gave a new turn to this debate, and made the sentiment respecting it in the heart different even where the language was the same. A similar remark applies to the other great question, which belongs more strictly, as every one will acknowledge, to the sphere of *metaphysical* theology. The older theology starting from the highest ground, from the assumption of an all-creating, all-energizing will, sought to discover how the movements of the human will could harmonize with or resist this. In the time of the Reformation the strong assertion of the principle of faith, of a man's right to claim a distinct relation to his Maker, gave a kind of precedence to the acts and energies of man, and made the controversy turn upon the point, how the power, whereof a man becomes conscious, is modified, controlled, or created by the energy of the higher will. And thus this controversy became, in fact, the seed of all the metaphysical questions of the next three centuries, even of those which had the least of a theological character, as it might not, perhaps, be wrong to affirm that the sacramental question was the seed of all the great moral arguments which were carried on during the same period.

Pantheistic
philosophy
in the papal
countries.

But though there was this manifest direction of thought towards the subject of human powers and energies, it was scarcely to be expected that while those powers and energies were in their full exercise, questions about their nature would, as such, excite any great interest. The directly philosophical controversies of the XVIth Century, therefore, as distinguished from the theological, did not as yet distinctly assume the new impress. By far the most interesting of them were carried on in those countries which were still under pontifical dominion. They were struggles of the awakened spirit in that time to break loose from the tyranny of prescription and logic, and to assert a freedom for speculative men, which practical men in those countries had not been able, or, perhaps, had not sought, to achieve. The Protestant divines, who had found a practical reality, were, as we have said, content to let Aristotle reign in the schools; nay, were eager to main-

tain his authority, and by degrees, as their controversies with each other and the Romanists increased, became really attached to and enslaved by the logical forms which they at first only tolerated as needful for certain purposes. The free spirits who had been nursed in Italy under a clear sky, and amidst forms of beauty appealing to the imagination and the heart; who had felt the impulse given to the world by the ancient literature; who had caught the iconoclast spirit of the Reformation, though they entered little into its peculiar objects and proclamations, naturally wandered into quite another region. The dry intellectualism of Aristotle was to them intolerable. Could it be that the aspirations of their souls after the good and the beautiful, aspirations which they shared with the great men of old, with Plato, and Philo, and Plotinus, were all to be tied down in formulas? Could it be that the divine nature admitted either of such limitations, or of those sensual limitations which a corrupt priesthood had invented to please the vulgar? Could it be that the fair universe which lay out before them endured restrictions which even the minds of its ignorant beholders disdained? Such thoughts as these brooded over the spirits of many men in this time, but took possession of none so completely as of *Giordano Bruno*. They gave birth in him to a scheme in which noble thoughts respecting God, unsustained by a clear perception of the ground on which men may have intercourse with him, mingled far too closely with bright and clear visions concerning nature. The result appears to have been a Pantheism which was called Atheism at Rome; and for which he was burnt by men who had themselves and their own corruptions chiefly to blame for any aberrations into which a spirit, apparently longing after truth, was tempted in the pursuit of it.

Moral and
Metaphy-
sical Phi-
losophy.

Giordano
Bruno.

In many ways the history of Giordano Bruno is important, especially as illustrating the origin and symptoms of the like faith in later times. But it is most interesting to us in this place as an indication of the new feelings respecting *Nature* which were beginning to work in men's minds. We observed, that the physical speculations of the first Greek school were closely connected with the sense of power which was awakened in commercial colonists living under small organized governments wherein each man had an interest in the midst of the great Asiatic Empire. And though these inquiries seemed wholly turned towards nature, we observed that, by a careful consideration of the notions and schemes to which they gave birth, we might discover that the student was not really so much seeking for an explanation of natural phenomena, as for something analogous with, or the foundation of that which he had become less distinctly conscious of in himself. In this way we traced the very origin and meaning of metaphysical inquiries in their earliest form. They were attempts on the part of men to compare their powers with the powers which they saw at work in the world about them. Supposing this observation to be founded in a general truth, and not merely deduced from a particular experience, it ought to receive illustration from the history of the time at which we have now arrived. Strangely different as the position of the nations in modern Europe was from that of the Greek colonies in Asia or in Italy, there was this in common between them. The feeling of human power had been strangely and suddenly developed, and that power had especially been put forth in practical meditation upon civil affairs.

Bacon.

His dis-
cipline.

Though the governments of the different nations had been for so long a time shaping themselves into form and consistency, it was now first that men began to think distinctly about governing, to consider it as an art. In every direction, under every variety of character, moral feeling, religious faith, this tendency and impulse might be seen to characterise the XVIth Century. The monarchs who ushered in this period were Henry VII., Louis XI., and Ferdinand of Spain. Machiavel was one of its early teachers; Calvin and Loyola, with the two most opposite sets of purposes which it is well possible to conceive, were each in their respective spheres devising schemes and laying down plans of government. Lastly, a complete political discipline was matured by the Guises and our Elizabethan statesmen. Much might be said of the effects of this temper on the morality of the time, especially in producing that prudential standard to which so many in their outward acts conformed themselves, who nevertheless did homage in their hearts to higher principles, and even lived for the sake of promoting them. All such observations would receive the greatest light from the history of a man whom we now advert to on quite another account as the founder of physical science in modern Europe. The student at first is somewhat puzzled in trying to connect *Francis Bacon*, the most astute and profound of political observers, with Francis Bacon, the author of the *Novum Organum*. But history seems to show very clearly the point of coincidence between the two characters, and to prove that the impulse to the observation of nature springs first of all from that sense of intellectual lordship whereby a man is able to feel that he has that in him of which nature may present many likenesses, but to which it can offer no parallel. Such a previous initiation into human affairs was also it would seem a necessary preparation for the particular work which Bacon was destined to perform. It was his calling, as we have hinted in former passages of our sketch, when speaking of the connection between his method and that of Plato, to deliver the study of nature from its subjection to the forms and conditions of our minds, to show how things may be known as they are in themselves, to prove that we are not bound to make ourselves the standards by which we judge of the objects which we behold. To effect such an emancipation as this—an emancipation, be it ever remembered, not from that which is in itself untrue, not from certain shapes and formulas invented and devised by men, but from those true and undoubted formulas by which the operations of our understandings are regulated—it was necessary that he should have an extensive school discipline. But it was surely as necessary that he should be taught by converse with men and their acts, that there is practically another kind of procedure than that which the schools follow; a way of entering into and becoming livingly acquainted with the feelings and conduct and purposes of beings, who, though of the same race, are in all individual tempers, circumstances, tempers, and habits different from us. Such a discipline, or, at all events, the character of mind which made such a discipline congenial, and induced him to enter into the studies that appertain to it, was a kind of needful induction to the belief that we can by some means feel our way into a clear, distinct, and living apprehension of the forms which the outward world presents to us, and that we can ascend to a knowledge of the actual laws, strange and mysterious as they may be, by which the state and movements of these forms are

determined. We have called this a belief; for beyond all doubt a faith in the possibility of attaining the end in this as in all other cases of real discovery precedes and sustains any attempts to ascertain the means of arriving at it. But for this faith something more was wanted than even that subtle and refined instinct which had been cultivated by Bacon's studies of men and converse with men. The recognition of an absolute ground of all human as well as all natural laws, the belief of his having actually made himself known to his creatures, and of its being possible for them to have a knowledge of him cleared from the fantasies and idols of their own imaginations and understandings, was the necessary foundation of all this great man's mind and speculations to whatever point they were tending and however at times one or both might be darkened by too close a familiarity with the corruptions and meannesses of the human world, or too passionate an addiction to the contemplation of the natural world. Nor should it ever be forgotten, that he owed all the clearness and distinctness of his mind to his freedom from that Pantheism to which the last great thinker of whom we were speaking so unhappily yielded. If he had in any wise confounded Nature with God, if he had not entertained the strongest practical feeling of men being connected with God through one who had taken their own nature, and not through the forms of the universe, it is absolutely impossible that he could have discovered that method of dealing with physics, which has made a physical science practicable. Pantheism—the *theory* whereof Paganism in its Greek and Indian forms is the legitimate and the only possible practical exposition—naturally disposes to that vague admiration and adoration of nature which was the great hinderance in the old world, and to a certain extent in the middle ages also, to the honest and steadfast examination of its wonders. To free men from this bondage, as well as from that materialism, partly the fruit of it, partly the reaction against it, which disposes us to look only at the surfaces of things or at the atoms which compose them, not to inquire after their secret powers and principles, was one great part of Bacon's duty. In fulfilling it, he did, as we have remarked before, fail in the homage that was due to his great predecessors. He never sufficiently showed in what sense Aristotle's principles, though inapplicable to realities, were nevertheless true and necessary. He never fairly acknowledged, or perhaps perceived that Plato, though he failed utterly in discovering the laws of nature, had asserted his own principle of knowing things in themselves, and traced out a method by which that knowledge is to be attained as clearly as Bacon himself. Both offences have been severely punished; crowds of sciolists have arisen, who, while abusing Bacon's name, to slander the two leaders of the old philosophy, have been, in fact, undermining his principles far more than theirs. Those who are really in earnest for his reputation, or for the cause of science itself, will endeavour to divest themselves of this bigotry, and will perhaps find themselves compelled to acknowledge that they cannot show their reverence for him better than by proving that the doctrines, which have now for two centuries been acting upon Europe usefully or mischievously, are not really in contradiction to those of men, who exercised so vast an influence over it during the sixteen previous centuries.

It will not be supposed by those who have gone along with our remarks on the analogy between the

philosophical movement of this age, and in the earliest age of Greece, that Bacon, by giving a new impulse and direction to physical studies, made those of which we are treating less popular or interesting. Following out that analogy, they would be prepared to expect that at this time the word metaphysical would acquire precisely that meaning which we have supposed to be its primitive one—in other words, that those who devoted themselves under the Baconian influence to inquiries respecting man, would propose themselves this question above all others for solution,—In what respect do the powers in man resemble or differ from those which we observe in nature? They will expect that those higher questions which were gradually developed out of this in the course of Greek speculation, those we mean which concern Being and Unity, would indeed be continually presenting themselves to men's minds, but would by no means form the principal or characteristic subject of their thoughts. They would be prepared also for a much more marked and sharp division between metaphysical and moral studies than had existed in any age subsequent to Christianity, perhaps we might say in any age since that of Socrates; lastly, they will easily believe that, as in those two former ages, men were occupied either with purely transcendent questions or with the relations of men's minds to that which is transcendent, theology and the revelation, which was believed to be the exposition of its truths, would much more directly connect itself with philosophy in them than in this. In the first case, philosophy would without any violence, as a mere matter of course, deduce itself from or refer itself to the principles of a higher science, because the subjects which it was contemplating in one aspect were those which that science was contemplating in another; in the latter case, on the contrary, theology would be rather brought in to supply gaps in the system which philosophy had tried to construct, the scriptures or the church appealed to as authorities against some of the conclusions at which philosophers had arrived. The datum upon which the earlier ages proceeded in all their thoughts and speculations was, that man is a supernatural being, treated as such by his Creator, even when he had himself abandoned his prerogatives, restored by a great redemption to his rightful position, enabled to claim it and to maintain it by a continual divine interference on his behalf. Now though this doctrine still remained as the foundation of the national faith and institutions in every part of Christendom, the men who were especially to govern the thoughts and speculations of the nations started from a different point. They were to contemplate man and nature side by side; not to assume any dignity in one above the other, but to try if they could find out whether they were subjected to the same laws or to different laws, whether they had the same constitution or a different constitution. Such we believe to be a fair description of the problem which was set before the men of the XVIIth and XVIIIth Centuries. We cannot regard without the liveliest interest their different attempts at the solution of it, or doubt that each one who had any honesty or insight, nay that one here and there who had not much of either, has contributed his quota of observation and experiment towards the settling of it. We do not believe that any one of these helps is useless or unnecessary. Nay, we do not doubt that even the speculations of these philosophers with which we have least sympathy may be turned to good account. We cannot for instance much

applaud the *destructive* tendencies for which some of them were conspicuous, because these would go to set aside facts which we believe others of them established. Neither can we in general rest satisfied with their *constructive* attempts, that is with the efforts of each to do more than the work which we conceive was set down for him—to provide a system, when all he had to do was to realize some fact. Yet we conceive that we could not well dispense with their destructive doctrines, seeing that these serve to determine the limits of their speculations and the exact amount and worth of that which they did see. Even less could we dispense with their crude attempts to form a complete and circular system; for these do not only supply most valuable admonitions to us of this day, but also testify to a want which these builders felt must be supplied in some way, whether they could supply it or no. Such are our convictions, and in this spirit we shall give a catalogue raisonnée of the most remarkable metaphysical writers in these centuries.

It is a different question how we are to treat those moral inquiries which were pursued sometimes separately, sometimes in conjunction with these respecting the nature of human powers and faculties. When we discover the same disposition to subvert the distinction between Right and Wrong which we noticed in the Greek Sophists, it seems hard to abstain from the same phrases of indignation which we permitted ourselves to use respecting them. And such, no doubt, it was most right for those to utter who heard these truths assailed, and observed, as Socrates did, the influence which the contempt of them was producing upon the youth of their land. They were not to wait for such persons to confute themselves, or for events to confute them. They were to assert strongly and clearly what they felt, for the good of their own age, and as a witness to those who should live afterwards. He who records a series of moral speculations may, however, take a different course. He need not go out of his way to invent an answer to those who have doubted or denied that there is any order in the moral world. He will find the answer written in sunbeams upon the history of the time. He has only to record facts, and it will be seen whether or no all the denials of all the philosophers that ever lived can destroy this order, or prevent it from making its strength manifest when it has been violated.

Two remarkable men born within a few years of each other, one in France, one in England, may be said to have given a character to all the period which followed them: these were *Descartes* and *Thomas Hobbes*. The former of these furnishes a remarkable illustration of the view which we have taken respecting the new direction of human thought. No one aspired more than Descartes to introduce a complete system of philosophy, to be a theologian, a physical philosopher, a moralist, and metaphysician in one; few persons probably entered upon the task with more of diligence and talent combined to assist them in accomplishing it. Yet irresistibly all his thoughts were drawn to the one question,—What is this mind of ours, how is it like or unlike the things with which it deals, and over which it exercises control? He might have a grand scheme or theory of nature, wonderful vortices, with most ingenious and not to his mind irreverent methods of connecting the world with its author. But underneath them all, Doctrine really giving them their value to himself, and in the main determining their influence upon after times, was his thought.

attempt at an answer to this one inquiry. "I am because I think; this *thought* makes the difference between me and all other things." The two suggestions which arose out of this, each having respect to one of the two kinds thus compared together, determined the other most important parts of his scheme. If other things are without thought, what can be positively affirmed of them? Simply that they are combinations of atoms. The qualities which are attributed to them indicate only their effects upon us; every thing that has not a soul can be dissected into its parts; so far Democritus was right. He was wrong only because he made the soul one of these atomic, divisible things. But what is the thought which is the essence of this soul? Whence comes it? Being its essence, it must certainly in its highest sense be within it. Thoughts, it is true, come into the mind. It receives thoughts and creates them. But there must be something below all this. There must be some thought which is innate in the mind itself. And here is a link between our minds and the absolute being. We have an innate thought that He is—a witness which to us is perfect and irresistible. Moreover a man thinks that he is free; how could he think so if he were not free? In the thought lies the freedom, even as in the thought lies the demonstration of the existence of God. Every one will surely feel that the man who proclaimed these positions was not merely uttering dreams. There is something in them which has a meaning, and which must be important. Let us wait and see how much of what he says will make itself good against men who have also their own words to utter. In the mean time let us be sure of this; Descartes has told us something about ourselves; he has discovered that we do think, and that this thinking is no trifle, but, whatever it be, a most solemn and mysterious process.

Thomas
Hobbes.

His psy-
chology.

When we speak of *Thomas Hobbes*, our thoughts turn, and rightly turn, to his political writings. These embody the character of the man, and without them all his other speculations would be unintelligible. Nevertheless, we ought to consider him also as occupied with the question respecting the relation between man and the rest of the universe, which we have spoken of as characteristic of this age. That which struck Descartes as constituting such a strange difference between man and all things else, that he could think, did not present itself to Hobbes as at all a remarkable peculiarity. Thought appeared to him simply in connection with that which we think about. There are certain things submitted to us with which we have to do, certain bodies which we can handle and dissect; these form the real subject upon which our minds exercise themselves, and these, and these only, are the province of the philosopher. This was very decidedly settling the question in the opposite way; it was determining that a man is not under any different law from the things about him; and this was precisely the point at which Hobbes was aiming. All nature is subject to certain necessary bonds and conditions; it cannot transgress its rules and boundaries; neither can man; it is merely a delusion to fancy that he has any more freedom than the rest of the universe. A series of previous powers and influences acting upon him determine him to be what he is, and to do what he shall do, and that thing which he calls a Will is just as much at the mercy of these influences as any other part of him. But then what does Society mean? How is it that men form commonwealths and mingle together with a sense of fealty to a common head and mutual

obligations to each other? Is not this different from some natural compulsion, such as mere bodies obey? How do they come into this state? said Hobbes. Look into the history of our own time and you shall see. What has been the result of our eighteen years of fighting in England? We began with a monarch, we have ended with one. Men have fought for ascendancy till they were tired, then by mutual compact they have stopped; they have felt that there must be a power over them, and that there was no help but to obey it. Do you want any other proof of the way in which society formed itself at first? A set of warring atoms called men struggled each against the other. Then came the notion of combination; two or three conjoined were a match for many separate ones. From this combination comes fellowship; men at last submit to one power through fear of each other, and he, by all influences that he can exercise over their fears and hopes, maintains his dominion. But it is mere power and necessity which rule just as much over these human creatures as over all others. Thus then we learn both what is to be done and what is to be known. It is most needful to know the nature of animals generally, and the ordinary laws of the universe which they obey: this is the subject of philosophy in its larger sense. It is most needful to know the nature of the particular animal you govern, to know all the influences of fear and hope which act upon him and determine him one way or another: this is psychology. It is most useful to know all the ways of turning these hopes and fears to account for the purpose of keeping him in subjection: this is politics. Pursuing these studies, and practising the art to which they lead us, we may avail ourselves of all helps—from sacred lore as well as profane; from the terror of superior power as well as the agency of ordinary compulsion; only we have to recollect that all these are means to an end. They are all used for the purpose of helping men to be in the only state in which it is tolerable for them to exist.

Such is *Thomas Hobbes*, the strongest of all dogmatists, to whom may well be applied the description given of the animal which has furnished him with the title of his greatest work: "*His scales are his pride, shut up together as with a close seal; one is so near to another that no air can come between them. They are joined one to another, they stick together that they cannot be sundered. The flakes of his flesh are joined together, they are firm in themselves, they cannot be moved. His heart is as firm as a stone, yea, as hard as a piece of the nether mill-stone.*" An example of a compacter style than his, with less of grace and freedom in it, our English language does not supply; nor perhaps has our English soil ever raised a more closely compacted man with less of affection or imagination. Yet we conceive there is much to be learnt from his writings. His stern demand for some object upon which the thoughts should exercise themselves, so that they should not merely be busy with their own workings, is in itself useful and important. His discovery that there is an Order or Government meant for man, that he, as much as any natural creature, nay more than any, must be in subjection to something, is surely a most important truth, which if not now for the first time discovered, it is at least valuable to receive a recognition of from such independent testimony. Nor ought we wholly to undervalue even that piece of imaginary history, his account of the way in which men fought themselves into subjection. Doubtless no such event is recorded, and all histories,

sical Phi-
losophy.

so far as they are authentic, supply the strongest evidence that it never can have occurred. But is it not valuable even in this light as a horrible fantasy? Do we not feel that if no civilized nation has ever emerged out of this state of division and tumult, many may have plunged themselves into it, and may be plunging themselves into it now? Is it not well to know what man would be, if he were not connected by any bonds of fellowship with other men, what he may become if he break loose from that fellowship? We may get then, we think, so much of clear gain from these destructive speculations, and this also; the assertions that man has no Conscience and no Will, are found to be inevitably connected in the mind of the most consistent of thinkers with the doctrine that the power to which he is subjected on earth must be an absolute power, and that all spiritual influences which are exerted over him must act mainly upon his fears. It will very much assist the student in his subsequent investigations if he devote some time to a comparison of these remarkable thinkers, who foretell in a manner the habits of thought which were to prevail throughout this period. The obvious distinction between them is, that one affirmed man to have that in him which is *metaphysical*; that the other reduced him to the same rank as all other creatures, differenced only by the possession of a more cultivated organ of calculation, and a livelier sensibility to objects of terror or enjoyment. But our view of this opposition is very imperfect if we do not observe on what ground it rests. Descartes the Mathematician believes that Thought to be the most essential part of man which he finds necessary as the basis of a demonstration. Hobbes the Politician can find nothing in a man separated from his fellow-creatures but the lowest instincts; whatever is beyond this, therefore, he concludes must have come to him from without and not from within. Here are two lines of thought into which we see that men occupied with the inquiry respecting the nature of man as connected with other natures immediately diverged.

Relation of
Descartes
to Hobbes.

Politics and
mathema-
tics.

Of the one which our countryman traced out we shall have to speak presently. The other it is equally needful to work in its different windings; still more to feel clearly what was its starting point. The very existence of such a science as *mathematics* had ever been a warrant to men that there is something fixed and certain, not dependent upon the caprices and accidents of our minds. We have seen what hold it took of the mind of Pythagoras, and how necessary Plato considered it as an induction to all philosophy. But we may easily conceive what new dignity was added to this science now that nature had become the great subject of study, and now that logic had lost so much of its interest. We cannot wonder then, that when men began to study the nature of their own minds, and to compare them with the things around them, they should have been struck above all things with wonder at their possession of a science whereby they were able to take account of the forms and relations of that world against which they were measuring themselves. What was it? What did it mean? And what above all must I mean who have it; who possess this means of attaining certainty respecting the things about me? Surely this certainty must appertain still more inwardly and intimately to myself. This *thought* must be the surest of all things, its oracles the most infallible; no other demonstration can surpass its demonstrations. So reasoned Descartes, and the full effect and consciousness of his reasonings revealed them-

selves in the mind of a man of deeper reflection and greater consistency than himself, *Bernard Spinoza* the Jew. Perhaps there is no one of whom it is more right to speak cautiously than of this remarkable person. His contemporaries felt only the mischievousness of some of his propositions, and took no account either of the circumstances of his education, of the truth which seems to have been working in his heart, or of the confusions which they and he shared together. It is to be feared that in this day there may be a somewhat violent reaction in his favour; many hastily concluding that a man of so much genius, and so much confidence in his own conclusions, if he were not a demon, must be a great prophet. We conceive that a man trained as he was to the reverence for an absolute Being, between whom and his creatures the rabbins recognised no actual mediator, disgusted as he must have been with their frivolities, and cut off from all political fellowship, must have needs hailed with delight the doctrine which Descartes proclaimed, that there is a witness of this Being in our own selves, and that there is demonstration in this very witness. Nor can we wonder that a man whose conscience witnessed to him that this was so, should have been led on to believe that he wanted no further light respecting this Being than this, that he was the ground and subject of his own thoughts, or that advancing a step further he should have been tempted to look upon the acts and movements of the universe as so many acts or properties of this Being, or that, he should have been able to trace with curious coherency and in mathematical sequence how these different thoughts were derived from each other. In expressing such thoughts, he might easily use language which on some who heard it may have had all the effect of Atheism, and yet have seemed to himself at the most immeasurable distance from it; in considering the forms and essences of the world as divine attributes, he must have slid into Pantheism, while yet there may have been a line of separation in his own mind even between this doctrine and his own, and while by his clearness of thought he may have enabled other and happier students more fully to perceive wherein its evil consists. At all events we may make this remark, that if this Hebrew carried the Cartesian doctrine to its furthest point, he was by his national position united to his acquired philosophy, at the furthest possible remove from all those political feelings and influences which, as we have seen, governed the philosophy of Hobbes. Both were, in their own way, most coherent thinkers; the conclusions of both were about equally startling and extraordinary, though diametrically opposite. May we not hope that, in some way or other, a point of coincidence may be discovered between their two modes of thinking; that politics and mathematics, the objective and the subjective speculations, may not always refute each other, and yet both put forward such a front of necessity and demonstration, and that this principle, whatever it be, which reconciles them may not be quite so alarming as either, when contemplated in its separation and singleness?

If we adhered strictly to chronology we ought to Jacob have mentioned *Jacob Behmen* before Descartes or *Behmen*. Spinoza. This man seemed born to show what deep thoughts may work in the mind of a mechanic, and how, if awakened, they will ascend at once into the region of the permanent and the universal, overleaping all the ordinary forms and limitations of the intellect; yet how inevitably they will take their shape from the age in which they were produced. It is now ge-

nerally admitted by those who have looked into the writings of this celebrated shoemaker of Goerlitz, that he is not to be dismissed with the vague phrase of vituperation, "an obscure mystic;" that his obscurity was in a great degree the effect of unacquaintance with scientific language, but that, through it all, may be traced deep thoughts respecting God and man, by which philosophers might be greatly profited. But our main reason for referring to his writings is, that they illustrate the tendency to speculation respecting nature, to compare Nature with Man, and to connect both with the mysteries of Form and Number which we have seen was equally characteristic of the most learned men. By Descartes and Spinoza, mathematics were looked upon as the great instruments for expounding their thoughts; and as the witnesses for something unchangeable. Behmen could invent a mode of exposition for himself, and he wanted no testimony respecting the being of God. But to him the relations of forms and numbers became mysterious objects which he could see moving and operating wondrously in the divine, the natural, and the subterranean kingdoms.

The Cam-
bridge
Platonists

A somewhat similar tendency may be traced in a very different class of men from any of those we have been speaking of, those admirable and accomplished writers who have been called the *Cambridge Platonists*, Cudworth, John Smith, Worthington, Henry More and others. These men, though they lived in the same stormy period as Hobbes, had not caught the influence of the political feelings of their time, but rather had been driven by disgust with them in the opposite direction. In their desire to escape from the dogmatism of the times they had betaken themselves to the earlier Christian authors, and had learnt to feel (as they did) that Christianity was the satisfaction and complement of Platonism. But though they thus strove to cast themselves into another period, they really received a very strong impression from the one into which they were born. They looked upon Descartes as a kind of interpreter of Plato, connecting his thoughts about the immateriality and immortality of the soul with the discourse in the *Phædon*, and eagerly adopting his atomic theory respecting the rest of nature as a homage to that which is intelligent and voluntary; and the deepest thinkers among them seem to have been drawn by an irresistible impulse into Pythagorean and Talmudical speculations respecting numbers and forms. In spite of the name which they have received, they appear to us more properly Cartesians than Platonists, being far more busy about the soul than about its objects, and therefore in their ethical system sliding into the Aristotelian doctrine respecting the distinction between the Absolute and the Practical, and teaching how to form Habits rather than to rest in Principles.

England
after the
Restoration

But Descartes, it would seem, was not meant to exert any decisive or permanent influence over the English mind. The power of mathematics made itself practically felt here in the *Principia* of Newton, and left the field of metaphysics and morals to political influences. Those influences had very much changed their character since the time of Bacon. In his day men had entered upon the study of civil life with infinite delight, as upon a real pursuit in which they could hope to make continual progress, and in which some new varieties of character and conduct would continually be presenting themselves. The simulation and cunning which even wise and good men seemed to think lawful were the result of their

looking upon policy as an art, an interesting pursuit in which men were to propose to themselves certain ends, and to accomplish them by what means they could. But this habit of feeling was not sound and true enough to last; real questions arose, real principles were brought into play, with which mere prudence and skill could not deal. Then came that civil war in which, amidst all its crimes and evils, strong and noble passions were called forth on both sides; on the one a reverence for the person of the sovereign associating itself with reverence for the ancient Church of the land; on the other, respect for law connecting itself with the assertion of each man's distinct Personality and Responsibility. The war had terminated; the party which had asserted the majesty of conscience and law had violated Law and trampled upon Conscience. The party which had supported loyalty and the church had triumphed; but the monarch who represented these venerable principles in his heart despised them. The more their legal authority was recognised, the less they were felt as having a ground above all formal law. Meantime commerce was every day enlarging its borders. Its principle of barter and exchange was felt to be living though other principles were dead, and speedily this principle began to be recognised as the one which all things obey. In such a time, John Locke appeared, a man of great simplicity and honesty, who was bred in a Puritan school to feel little sympathy with the past, who was gifted with a keen eye to observe what in the notions of his time was loose and disjointed—the relics of other ages now ill understood—who would not profess more than he felt or knew upon any matter, and who, because many talked of things which he was sure they did not understand, rather suspected that this was the case with all that had ever professed to see more than he did, who had the power of making men perceive how much they believed already, who was nowise able nor much pretended to enlarge the sphere of their belief, or discover to them what they had not yet apprehended. It was his undertaking to remove Mysteries from the science of Government by resolving that relation between the king and the people, which had hitherto been expressed in religious forms into the plain notion of an Original Compact; to remove all difficulties upon the question how men should feel respecting the differences of Opinion in each other, or States respecting the differences of opinion in their subjects by the simple consideration that we are all liable to err; to take away puzzles out of the path of the Teacher, by showing that Education is to prepare men for the business of life; to put men in a simple way of Conducting their own Understandings, by warning them of the danger of being influenced too strongly by this opinion or by that; lastly, to set all matters clear respecting the Understanding itself, by showing that it receives its Ideas through the Senses.

In saying this we are describing (as may be judged from the character we have given of Locke) the effect of his opinions upon a time which had implicitly adopted them before he formally set them forth, rather than the intention of their author. He had no feeling that he was producing books which were to terminate all questions, and set men's minds at rest for ever. He merely announced what he had himself thought about different subjects, and why he did not see his way to adopt the more remote and recondite principles which some had dreamed of. Or if he did fancy that his doctrines on Government and Toleration were all that were needed, at

least in his *Essay on the Human Understanding* he seems to have been fully aware that he was throwing out hints, not supplying a system. It is this honesty, and his indifference to inconsistencies, so long as he can make known what seemed to him on the whole true, which we believe to be the secret of his permanent fame, though it has very little to do with the popularity of his opinions. He is admired by a multitude of unthinking persons, because he is supposed to have swept away, or at least effectually undermined, all the feelings, notions, and habits of thinking which had connected themselves with the idea of philosophy from the earliest Greek ages to his day. He receives, and we hope will always receive, from sensible men a tribute of respect, not to be disturbed by the exaggerations of fanatical admirers or by a painful feeling that he has been the occasion, though not the cause, of much conceit, ignorance, and contempt, because they believe that he did remove some confusions which it was necessary to remove; that he affected less than most men to build when he was only pulling down; and that though he laid no deep foundations, he was in some degree the beginner of a series of experiments which it was needful should be made, and which were to terminate in the establishment of principles very different from any which he acknowledged. We will say a few words on each of these points.

After the notice which we have taken of the ideas of Plato in an earlier part of this article, it is quite superfluous to remark that the doctrine contained in the first book of Locke does not affect them in the least degree. Locke begins with assuming that Ideas are identical with Notions and Impressions, and, having made this assumption, proceeds to prove that they are derived to us through our senses. It had been Plato's great object to explain what he meant by an Idea, and how it differs from a Notion. Locke did not take the pains to understand him, perhaps it was not worth his while, but at all events he did not confute him. He does not indicate in any one syllable of his essay that he had a glimpse (we do not say of Plato's meaning, but) of the possibility that he should have a meaning. But while we admit this, we are not prepared to say, as some have said, that there was no opinion afloat to which Locke's refutation directly applied. We conceive the Cartesian doctrine of innate thoughts, though it may, by nice distinctions, be cleared of some of the absurdities which Locke ascribes to it, must ultimately expose the holders of it to the perplexities of which he takes notes. Of course Descartes would have denied that he meant by an innate idea a proposition clothed in words. But had he done anything to show how these ideas in the mind can be substantiated except in some form of words? If not, he was still open to Locke's argument, and he could only escape from it by betaking himself to a region with which his speculations do not intermeddle. There was then something for Locke to do in the way of destruction; and though he may have fancied his doings in this line much more extensive than they were, we ought to give him the full honour of that which he actually achieved. On the second point, the absence of system in Locke's writings, we need say nothing. It is admitted as much by his friends as his foes: the former affirming that he left something for his successors, Condillac and others, to complete; the latter urging it as one of his evil characteristics that he sanctioned so loose and unscientific a method in philosophy. Without wholly denying the last charge, we must yet allege this freedom from the ambition to be a

VOL. II.

Babel builder as one of the conspicuous proofs of his singleness and sincerity of purpose.

The last point is the one we are most anxious to press upon our readers' attention, that Locke did actually originate a series of the thoughts and experiments which have been in their issue of the greatest value. It may seem incredible that the proposition, "a man derives no knowledge except from his senses," should have any other than a negative importance. If we have *only* eyes, ears, and hands, we ought to be told so undoubtedly; but are we under any great obligation to a person who informs us that we *have* eyes, and ears, and hands? We answer, yes, we are. This communication, though it may not seem in itself very new, may be the first necessary step to truths which we shall not recognise with nearly the same facility. Such we believe to be the case. We believe, as we said before, that a new problem was set before men—to find out what their own faculties are, what they themselves are. We have seen two or three great attempts at an examination of this question. But they have taken in too large a sphere of thought; they have mingled themselves too much with the doctrines of a former age, and have rather indicated all the points hereafter to be discussed in this, than addressed themselves determinately to any one. It was needful to begin at the beginning; to see what the very lowest thing is that a man can do, in order that we may proceed steadily and gradually to find out what more he can do. May it not be also possible, that the order in which a man's faculties are to be trained and educated is precisely that in which, in the course of such experiments as these, they will reveal themselves to us? May it not be that men who were only perplexed as to the way of cultivating their own minds, or the minds of others, by being told that they had certain great and divine perceptions, may in this way be led to recognise one perception and intuition after another, till at last one is found to be there, which did indeed answer, and more than answer, to all that had been suspected of it? Supposing this to have been the case, we should surely see a very good reason not only for the existence of Locke's speculations, but why they should have been cast in that limited form which, in spite of all national prejudices and feelings of personal respect, we are bound to confess that they assumed.

We have mentioned by what circumstances in its France moral and political history England had been prepared to receive the doctrines of Locke, as well respecting the nature of government as the laws of the human understanding. There was not as yet the same impatience of mystery among the thoughtful men of France, though that nation was hasting on to a still more passionate abhorrence of it.

We noticed the establishment of the Jesuit body as one of the proofs of the strong impulse towards political organization and political studies which characterised the XVIth Century. This body strictly preserved the marks of its origin. It became the great teacher in the art of politics and in all other arts for the sake of this. To maintain the great universal polity of the church against the shocks it was receiving from the new life in the particular nations was unquestionably the object which was more or less consciously present to the minds of its founders. In their noble efforts to bring Pagan nations within this polity, they presented the fair side of their scheme. But it was a *scheme* still, a human invention for the sake of keeping up what the

sical Phi-
losophy.

Jesuits believed to be a divine institution. In Europe, therefore, the divine body which was to be upheld, and the human body which was to uphold it, became speedily confounded in men's minds. The Jesuit society was practically universal society which overlaid the national spirit in each country, but certainly never led men to dream that there was any thing higher or more celestial than that. And soon a system of morality grew up which was the natural fruit of this confusion. In describing this system it is common to say that provided good ends were sought all means were considered lawful. We do not think this phrase exactly describes the nature of the evil. The Jesuit body were guilty of any thing rather than an indifference about means, or a preference of ends to means. One would say that their great fault lay in the want of a clear perception of their own ends, and in the extraordinary devotion of their whole skill and subtilty to the invention of plans and projects. Give the followers of the Institute one clear and manly intuition of a high object, give them but the power of distinguishing between the church which they thought they were defending, and their own system, and we have no doubt that the means would have righted themselves, or to speak more truly, that none would ever have occurred to them but such as honest men might approve. And it was by keeping out of sight all high spiritual objects while they were training men with unrivalled skill and diligence to the use of instruments, by darkening their perceptions respecting the true nature and order of society, while they were suggesting all sage hints respecting the arrangements for carrying it on, that they introduced that mechanical and materialist philosophy of which the next age was to present the perfect form as well as the final results. At present there were (as we said) in France many brave and noble witnesses against this morality. Whether there may not be something in the *Provincial Letters* of that very spirit which they are attacking; whether they may not exhibit a too curious and skilful mode of dealing with points; whether the tone of scoffing which pervades them may not have helped to strengthen a temper already too manifest in the countrymen of Pascal, we do not wish curiously to inquire. At all events the deep meditative spirit which came forth in his other writings, and in those of the Port Royal School generally, and thence diffused itself among a noble and conspicuous part of the French philosophers, touching even, though not penetrating, some of the poets of Louis's court, assuredly helped to preserve the mind of France for a while from the corruption which on so many sides was threatening it. As metaphysicians, these eminent men were manifestly outgrowths of the school of Descartes, inclining to the mathematical rather than to the political, to the subjective rather than to the objective habit of mind. They rather took the polity of the church for granted, than much investigated its nature, abhorring politics as Jesuitical. It was likely that with this tendency they should bring forward into strong prominence the views of Augustine, and should rather perhaps dwell upon those which belonged to the period of the Pelagian controversy, than to those which are developed in his earlier writings. It was the tendency of the Jesuits to make human contrivances every thing, and practically to exclude the feeling of the divine will being the ground of life and law to man. If the Port Royalists sometimes too exclusively pressed the opposite doctrine, they must be judged leniently as men who had a fierce battle to fight, and were maintaining it under

Pascal and
the Port
Royal
writers.

great disadvantages. On purely ethical questions, their writings, with those of Malebranche and Fenelon, are, we conceive, of great value, but more to us than their own age. The reason is contained in a remark which has been made already. It was the particular province of this period, as we judged from certain indications at the beginning of it, to expound the nature and foundations of relative morality. But the position of the Port Royalists and even of Fenelon made them unfit to deal with this subject. They were led therefore almost inevitably into discussions which, though of a higher nature in themselves, were far less needed for the wants of the time, and, as we conceive, could in this time only be treated partially. This observation applies especially to the very important controversy between Fenelon and Bossuet on the question of the real object which the Christian moralist is to set before himself. "Selfishness," said Fenelon, "is the destruction of the human spirit. If it proposes to itself selfish aims either here or hereafter, it is not in its true state. Pure love, and the delight in him who is love, are its only legitimate objects." "By saying so," said Bossuet, "you destroy all the motives and excitements to virtue, all those hopes of a reward and fears of punishment hereafter, by which men are stimulated to act and exert themselves." The Pope of the day felt there was so much in Fenelon's doctrine which corresponded to the language of the earliest ages of the church, that it was long before he could determine to condemn him. But the spirit of the time was too strong for him. Fenelon might be asserting a truth—we believe he was asserting a great and deep truth—but it was one which had need to be connected by certain links with the life of man upon earth. If this morality were true as to the ultimate end, all our life here upon earth must be a discipline and preparation for it. How this was, how there could be a ladder connecting earth with heaven, the lowest duties of family life with the highest and most transcendent visions, Fenelon might occasionally dream; but his circumstances forbade him to develop the idea. His opponent was therefore able to take up what seemed to most men a safe practical ground, a ground which assuredly it was not safe to abandon, unless some firmer ground could be substituted for it. The most powerful member of the Gallican church declared Christianity to be a system of selfish morality, and after a feeble resistance the Romish Pontiff ratified the decision. The XVIIIth Century was to show what such principles acknowledged in words, and acted out in life, could do for the French and the Romish church, what sort of rock they would prove when the rain began to descend and the winds to blow.

But the Frenchmen and Englishmen were not the only philosophers of the XVIIIth Century. Germany, in the person of Leibnitz, was to give a very strong and clear prophecy of the works which it was destined afterwards to accomplish in this department. Though not speaking his native language, this philosopher had most of the characteristics which we have learnt of late years to associate with his countrymen: deep thought sustained by vast reading; a desire to find a common bond between sciences; a tendency to seek within us for the ground of that which is, rather than to contemplate the objects which are presented to us. In almost all these respects he is directly contrasted with Locke, in most of them he exhibits some likeness to Descartes. The Frenchman may be considered therefore the parent of his speculations, though he had seen clearly how vulnerable some

His theory.

of those propositions were which Locke had assailed. His discovery of a middle point between them, of a way in which the meaning of Descartes might be saved without the assertion of innate thoughts, is, we suspect, the real and permanent treasure which he has bequeathed to us. You say that there is nothing in our understanding which is not derived to it from the senses. True, said Leibnitz, but there is the *understanding itself*. The importance of this proposition, simple as it may seem, is, we believe, very great indeed. It was in one sense the strongest practical answer to Locke. It was the overthrow by an assertion, which appealed as directly to men's experience as his own did, of his theory so far as it opposed all inquiries respecting man himself, and led to the mere contemplation of his accidents and circumstances. It was a direct assertion that a man not only has and receives something, but *is* something. Looked at in another way, it was the second step in that series of experiments which Locke had commenced. A man has senses, said Locke; this was the last and lowest thing that could be said of him. He has something which *understands*—which stands below these senses, and can receive and deal with what they tell him; this was Leibnitz's supplement to that truth. But Leibnitz had other and higher aims than that of asserting such a proposition as this. Bayle had laid the foundation of French scepticism in his different writings, especially by bringing together the speculations of all past thinkers, and showing that they had arrived at no result, or that at all events the faith and the understanding had always been at variance. Leibnitz fancied that it was in his power to refute these assertions, that he could construct a *Theodicæa*, in which the doctrines of theology should be reconciled with philosophy. In making this attempt, he found himself led back by theology and philosophy alike to that question respecting Unity which occupied the Greeks and the earliest Christian age. A perfect self-subsisting Monad presented itself to him as the necessary condition and ground of all other being, as the reality from which all other realities are deduced. By this Being, this perfect monad, all things have been formed according to a pre-established harmony which is working itself out and manifesting itself through the imperfections of all individual creatures. This grand scheme must needs awaken, as it always has awakened, the greatest interest in thoughtful minds. They have felt that it does speak of things which they have need to acknowledge, that they cannot put it away from them with the words "This is nothing." At the same time they must feel, we think, that the scheme furnishes at best but the dry conditions, the logical form of a universe. As a dream, how much less beautiful it is than the Platonic Republic! How much less does it carry within itself the witness of being more than a dream. Surely it was not by such a theory that sceptics could be overthrown. They felt themselves in a dreary world of actual contradictions, a world in which they could grasp nothing that was real, in which shapes, and fantasies, and opinions were moving backwards and forwards in weary mazes, in which falsehoods and truths were so mingled together, that they lost their names and natures and became inseparable. What availed it to give such men the logical outline of a world, to show them that a harmony is conceivable? Let a man but have some glimpse of the reality, and assuredly the picture, even if it is but imperfectly drawn, will gratify him; but that any one should rise through the picture to the apprehension of the reality, where

every thing about him seems to contradict that apprehension, is indeed a vain expectation. Let us therefore give all honour to this deep-minded and enterprising German, acknowledging that he has realized the fact of our possessing an understanding, and giving him thanks for proclaiming it, but questioning how far that fact will go towards reconciling the confusions of the world, or how far it is possible to build up a system of theology and philosophy on the basis of it.

Among English thinkers, the one who seems at first sight to have received the strongest impression from the writings of Leibnitz, and to present the most striking parallel to him, is *Samuel Clarke*. He too attempted a demonstration of the being and attributes of God, and a solution of the puzzles respecting human freedom. He too brought a most vigorous understanding to bear upon this and all the other subjects which he handled. But the difference between the two thinkers is very remarkable. The demonstrations of Leibnitz have all a more or less direct reference to the demands and conditions of the intellect. The demonstrations of Clarke carry one into the outward world, and from its construction and formation would lead us to its Author. No doubt, the idea of an *à priori* necessity of a Divine Being is present to the minds of both; but the necessity in one case is much more derived from man's own constitution, and the need of certainty implied in it, in the other from the constitution of the universe. And this was the character which in the XVIIIth Century began more and more strongly to be impressed upon the English mind. As physical philosophy diffused itself, theology began to become physical also. The deeper men like Clarke, whose minds had taken their form and colour from mathematics, attempted *à priori* demonstrations; writers of feebler, though perhaps gentler character, contented themselves with deducing proofs of the divine existence, goodness, and wisdom from mere observations upon nature. Both alike assumed that man derived at least his primary knowledge of God from the external universe; both alike implicitly admitted the relations of God with man to be less close and intimate than his relations with nature. A revelation therefore was a supplement to the discoveries originally made in nature; nature told something, but not all; a Bible was sent to tell the rest, and to impart (what the outward world could not give) a knowledge of the laws which it had pleased God to establish respecting the conduct of his rational creatures. This was the only kind of language which was popular even among the divines of that day, who, of course, therefore thought very little of those mysteries which expressed the fact of a direct union between man and his Creator, and of those still more transcendent principles which are at the root of these.

It is obvious also that the question respecting the laws to which man is subjected—how far they resemble, how far they differ from those which other natures obey, must have received a new modification from this tone of feeling. In the time following the Reformation, the question was, How may the will of God and the will of man be reconciled? Hobbes changed it to—How can man's will be reconciled with his subjection to certain necessary natural laws? In this time, the distinction between the two questions was lost; they were supposed practically to mean the same—one being the more vulgar language of ancient theologians connected with some mysterious notions now obsolete; the other the language more suitable to a philosophical age. Along with this charge another should be noticed. The puzzle no longer

referred to the effect either of this will or these laws upon the internal life of man, but simply upon his conduct. Could he in his ordinary acts be considered free? Could he abstain from committing murder, or do a kind service if he liked—or was he determined to one or other of these acts by some previous compulsion?

This point deserves to be noted because it is connected with so much else that is characteristic of this time. *Conduct* was now become any thing. All the literature of the age dealt with behaviour or manners—its poetry, clear, precise, definite, where more is *never* meant than meets the ear, unless it be a double entendre—as much as any other portion of it. These manners therefore were more and more felt to be the characteristic of man. By them, if by any thing, he is differenced from other creatures. So that the philosophy of the age began to turn much upon this point. ‘What do these manners or morals mean? What is the ground of them? Whither do they tend?’ This was the main question, not excluding the other respecting the powers, perceptions, or intellect which Locke had discussed, but generally taking precedence of it. The argument led to many curious results, very unexpected, one would think, by those who began it. Let us mention a few of them.

We noticed at the time of the Reformation how the old chivalrous Catholic morality of the upper classes was encountered by a more practical, personal, domestic morality in the middle classes. The distinction was not effaced afterwards. The Sidneys and the Brookes of the Elizabethan age maintained a form of character which, though different from that of the old knights, was legitimately derived from it, and the same came forth in direct conflict with the other style of character in the cavalier of the Civil Wars. In the time of Anne and the Georges this character still survived, but under a very different modification. The aristocrat strove to distinguish himself from the plebeian by being a philosopher, by seeing into the real sense or nonsense of things which the multitude humbly believed. As, however, there were of course various grades of wisdom in the persons who adopted this fashion, so there were two very distinct forms of feeling in those who set it. The first appears in *Bolingbroke*. It is that of a man with considerable sagacity and knowledge of things explaining the construction and order of the universe, why this is here, and that there; why it is better for the sun to shine in the morning, and the moon at night; why some men had better know nothing, and some men know every thing; all which is so very plain, that there needed no revelation whatever to explain it to the world, for it is in fact a part of natural philosophy and religion. This is the scheme which Pope rendered into such excellent verse in the *Essay on Man*, though the doctrine suffers much in his hands, from the want of the aristocratic nonchalance with which Bolingbroke announced it. The other and far nobler type of patrician morality was seen in *Shaftesbury*. The loyalty and religion of the chivalrous ages, so far as it was grounded upon any belief of an actual revelation or of mysterious powers, he considered accidents of superstitious times. But the loyalty to an idea of something pure and lovely he acknowledged as a genuine principle which the higher class of men are able to cherish in themselves, and which does not require helps and appliances from without to sustain it. Of such ideals we have often spoken before. After considering them in Plato, and ascertaining what he felt that they needed to give them a ground of reality and to connect them with man, we

need not consider what is said of them by one so vastly inferior both in insight and in science; still it is striking to notice how, in such an uncongenial atmosphere as that of the XVIIIth Century, buds from this old stem could still shoot themselves forth, much nipt indeed by frost and blight, but witnessing to the strength and solidity of the original tree, and not perhaps less to the nutritive qualities of the English soil in which it had planted itself.

But Shaftesbury did not really carry on the experiments of Locke; he only threw out a hint in favour of an old principle, which seemed at variance with them. A humbler man, still occupied with the same kind of investigation respecting the meaning of those manners, or morals, or proprieties, which seemed to distinguish the human race from the inferior animals, threw out a hint, which we may fairly note as the third fact respecting the powers and perceptions of men which was fairly ascertained and realized. *Francis Hutcheson*, an Irishman, naturalized in Scotland, affirmed that man has what he called a moral sense, a faculty or tact, that is to say, whereby he distinguishes that which is comely from that which is base, that which is harmonious in action or character from that which is discordant.

This fact Hutcheson observed and set it down as an important fact. We think it is so: whether it is a fact which ever can become the basis of a system, a fact which can explain the perplexities and anomalies of the world, as some of Hutcheson's Scotch successors have thought that it can, is another question altogether; our business is merely to record the observations which different thoughtful men have made, and to claim that they should not be passed over or made light of. On this ground we claim that Hutcheson's Moral Sense should be allowed a place beside Locke's Natural Senses and Leibnitz's Understanding. We do not determine the importance of the principle discovered, we only contend that it is one.

But this sense of the appropriate and the inappropriate, of the harmonious and the inharmonious, what has it to do with me and my life? Can it tell me what I should do or should not do? If it cannot, is there any thing in me that can? This question was grappled with by a man of far stronger and sterner understanding than Hutcheson. It might be supposed that *Bishop Butler* would have derived his answer to this question from some transcendent source, that he would have appealed to the Bible or to the Fathers, as testifying that there is something in man to which the moral law appeals. But this is far from being the case; no man understood more fully the kind of problems which persons in this day had to work out, and the kind of helps they were to use in solving them. He set himself to investigate the subject just as much in a way of pure experiment, with as little reference to revelation, or to any other authority, as Locke himself had done. And proceeding on this ground he arrived at the conclusion; man has not merely a moral sense, he has a CONSCIENCE, he has that which tells him not, this is fair, this is foul; but, thou oughtest to do this; thou oughtest to abstain from that. Here we conceive is a fourth fact obtained, in a way just as formal and legitimate as any of the others. We may believe that, from the mode in which Butler contemplated the subject, there was a necessary limitation in his statements which, if that mode be not taken into account, makes them more partial, and therefore less true. We may believe that he was obliged to describe the conscience as being simply *in man* when the very idea of it,

sical Phi-
losophy.

Hutcheson.
The moral
sense.

The con-
science.

Moral and
Metaphy-
sical Phi-
losophy.

even as expressed by himself, involves the necessity of its being not merely in him, of its being a connecting link with that which is above him. But we feel at the same time how inevitable this contradiction was, and how much the evidence for the fact gains by the existence of it. Starting from premises, and proceeding in a method which made the recognition of a conscience scarcely possible, Butler is driven by the mere evidence of facts to affirm its reality, and by the very awkwardness and inconvenience of some of his phrases to indicate a higher idea of this power or perception, not perhaps than he implicitly recognised, but than any which the line of argument he had taken up enabled him to express.

Social
affections.

But this was not the only fact which this remarkable man was permitted to add to those which had been realized by his predecessors. The Conscience, with its formula, Thou shalt, or thou shalt not, might seem to be expressly that which separates or individualizes. Is a man then intended to feel himself an individual creature? Is his association with his fellows merely an accident of his position, superinduced, as Hobbes had taught, by the fear of mutual destruction? Butler affirmed that the Social Affections were just as much involved in the constitution of a man as the feeling of self or self-love is; that you have no more evidence for affirming the existence of the one than of the other; that a man is drawn by as strong an impulse to his fellows as he is to assert his own distinct privileges and position; finally, that that Conscience which speaks with such distinctness and solemnity to each man's heart bears no stronger witness than this, that these social affections are true, and ought not to be violated. We think that the demonstration of this fact is quite as strong as the other, and therefore we should not hesitate to set it down as one of the principles which were added to that primary one of Locke, if we did not recollect that we had already announced a directly opposite theory from a person also of extraordinary vigour and acuteness, and that as yet we have shown no cause why one of these theories should be less tenable than the other. We must wait therefore awhile till we have some other test by which we can judge of their respective merits, or can ascertain whether there is any way of assigning some meaning to each which shall not clash with the other.

These three or four last discoveries might seem to be leading us in the opposite direction to that which we said was the bias of this age. They seem to show that man has something which is not merely natural, something different in kind as well as in degree from the other animals. Nay, they would seem to go further, to show that there is something in man not connected with his bodily structure, which is most important to him in all the practical operations of his life. The positions which were maintained about the same time by another philosopher appear at first sight to be of an entirely different character. *David Hartley*, a man of great honesty and simplicity of mind, and possessed of kindly affections and religious feeling, had entered with great earnestness into the doctrine of Locke respecting the derivation of our knowledge from outward objects through the senses; but he was convinced that this though a truth was not an ultimate truth. People may talk of receiving feelings and impressions through the senses. But how do they receive them? What are these impressions, and how are they derived to us? Hartley was struck with the wonderful connection that exists between the different impressions that are made upon us. Surely they are not casual and fortuitous, they must follow each other in an

orderly series, and would it not be possible to trace this series through all its links, to find out the key-note, and to see how each succeeding note vibrates in harmony with it? Such a scheme is surely possible, but if so, where are we to look for the key-note? On what part of us is it that objects make their impression? Most naturalists, most philosophers indeed of all kinds, would say, Upon the brain. Well then, by studying the nerves and fibres of this brain, we might convert this theory of vibrations into something more than a theory, we might actually trace in mathematical sequence how each impression, sensation, idea (for our readers must remember that the words in this philosophy are identical) arises, and how at last we arrive at the deepest and most complex ideas of all—those which refer to our own moral life and the being of God.

This Hartley has actually attempted—an attempt it seems to us undertaken with the worthiest feelings, as it is unquestionably carried out with the greatest ingenuity. Nor, we think, is it very easy for any one who reads his book to doubt that it has made some points good against all contradiction. One feels that the very conception of such a connection between man and the world, with which he is continually conversing, is almost a witness for its reality, whether Hartley has succeeded in tracing out the links of it or no. The beautiful fancy of a perfect adaptation between our bodies and the world that surrounds them, must, one would say, be more than a fancy; all power of taking in and delighting in the sights and sounds of nature witnesses its reality. The only point to be considered is, how far the theory will go. Are there not other facts which must just as much be taken account of as this fact of association? Is there not, for instance, this fact, that the man who has this brain is himself some one, that he must be before these associations could take place in him? Is there not also this other fact, that he actually exercises a dominion over that very nature which seems to be the origin of all these trains of association within him? But if so, this fact that he is, and that he has power over the inanimate world, are surely more closely connected with those moral truths, and with his relation to a Being greater than himself, than the fact of his outward associations ever can be. We believe, therefore, Hartley's book to be one of great usefulness and interest—to those especially who have some other solution of these deeper difficulties than any which he presents them with.

This conclusion might perhaps have suggested itself France. to some even in Hartley's own day. But there was a race of philosophers now rising to importance, who determined that any such weak attempt at the reconciliation of two kinds of facts which our English thinkers had in their different ways seemed to establish, was utterly ridiculous and impossible. We saw France a little while ago in a state of transition from a very high and mysterious philosophy into one which was to set all mystery at defiance. If we undertook to give a complete account of the sources of this change, and of all the accompanying changes in national feeling and character, we should have to record the melancholy too well known progress from the glittering glories of the early and middle life of Louis XIV. to the hypocrisy of his declining age, to the corruptions of the regency and the abominations of the next reign. But the direct origin of it must be referred to Descartes. The atomic theory of that philosopher survived all his other opinions, and it begat the belief among his countrymen that the only

mode of dealing with physical substances was by analysis. Nothing could be known till it could be dissected. Acquaint yourself with the atoms of which it is composed, then, and not till then, you understand the thing; this was the maxim which established itself almost universally in natural philosophy. Now the notion which men in this age formed of natural science had, as we have seen, the most direct influence on their moral inquiries. It was quite inevitable then, that an analysis of human nature should be demanded as the one necessary thing for the purpose of understanding what man is. And it was equally inevitable that when this analysis was undertaken, the philosopher who could lay his finger upon the last and lowest thing in humanity, and show how every thing else might be resolved ultimately into that, would be accounted the *Magister Sententiarum*, the seraphic doctor of the new school. To such analysis then one class, and on the whole the ablest class, of French philosophers betook themselves. They did not in the spirit of Hartley undertake to show how one sensation may give birth to another, till at last one knows not what high results may come of them. But they said deliberately and dogmatically—all these feelings and powers that you have talked of, Understanding, Moral sense, Conscience, or what you please, are nothing else but sensations, they shall be nothing else, and whoever thinks them any thing else shall be denounced as a driveller or a knave or both. It is obvious that if these propositions be true, philosophy both began and was likely to end in the XVIIIth Century; nothing had been done in the five thousand years previous to that time, and the little that was required to do might be finished in a very short time. One does not see why, if Condillac and Helvetius really did what they pretended to do, any more books need be written in the world besides theirs. They had got to the bottom of things, they had found out the foundations of the universe. There men might rest as they could; and so indeed these philosophers would have thought if they had not found a whole world of notions and opinions based upon another hypothesis than theirs, and if they had not felt that these must be swept away in order that hereafter something might, perhaps, be built up on the firmer ground which they had discovered. In this business of demolition, however, the analysts were not found to be the best or most accomplished workmen; Voltaire, Diderot, and the encyclopædists generally did not accord them any very large measure of their respect. They had no wish to make men think so meanly of themselves as they were likely to do if they adopted the conclusion to which Helvetius especially would have led them. It was better on the whole that men should have a considerable notion of their own powers, and that they should believe these powers to have been held in check by priests and lawgivers, than that they should think those priests and lawgivers had given them credit for feelings and sympathies which they never possessed. The habit of feeling then encouraged by these men was rather that which had prevailed for some time in England, the feeling that every thing which was not at once intelligible was absurd; the rigid pursuit of any one doctrine or idea was disagreeable to them. With much respect for physical studies as a counter-weight and a counter-mystery also (for this they felt they had need of) to theology, the whole tendency of their minds was essentially unscientific; for however much knowledge of mathematics some of them may have possessed, they valued it for the sake

of its results merely, and not of its method, and such a value, whatever name it may put on, indicates a quite unscientific character. In all questions of morals, politics, art, and history, the most superficial conclusions were those which they prized most, the most loose and popular language was that which they affected. One would not therefore confound with them the men of whom we first spoke, though in the main adopting the same opinions, and anxious for the same results. They were apparently a simple, dogged kind of thinkers, more pleased with their own speculations and less caring to please the salons. Nor ought we to turn away from their doctrines respecting human nature with that utter scorn and indignation which some have expressed. That analysis is not to be the exclusive or the principal ruler in either physics or morals, that both studies will speedily be extinct if it become so, we fully believe. But that it is of some value in both seems just as evident, and we think it proved itself so in this instance. To say (as Condillac in effect said) every thing in a man can be reduced to sensations, practically you have no need to take any thing else into account, is, we conceive, to make our own lives and society monstrous and incoherent dreams. To say; separate a man from every relation under which he is created to exist, from every influence that is acting upon him, above, below, around him, from things human and divine, abstract him in short from every thing but the world that he beholds through his senses; then he will be merely a creature of sensation, and we believe a truth has been uttered, which, if when thus stated it sounds rather like a common place, has yet, we believe, need to be uttered, and may serve to put down much vague and silly declamation respecting the dignity of man and the grandeur of his nature. In like manner when Helvetius fancies that he can build up a society on the groundwork of the principle which has ever been the destruction of it, we may take leave to marvel and to doubt. But when by lively illustrations, and with much acuteness, he proves that this principle does lie deep in man, that it ever has been and ever is asserting its pre-dominance in him, nay when he pushes us on to the position that man, not in some manner raised above himself, is selfish and selfish only, we neither reject the proposition nor condemn it as self-evident, but are thankful to him for having given us much cause for fear, for shame, and for wonder. We believe then we must class among the discoveries of this time, this one of Condillac, that man not only receives his first impressions through the senses, but that in the last grovelling state to which we can conceive him here on earth reduced, he becomes merely a creature of sensation; and this of Helvetius, that there is yet in him a deeper and more awful tendency than this; to pure, absolute, unmitigated selfishness.

The scepticism in France was in one sense the deepest as well as the most universal that ever existed in a nation. In another, one would say it was by no means deep. The philosophers doubted of every thing, or rather assumed it as a matter of course that every thing was false which they could not understand. But they were never really exercised with doubts, they never fairly looked doubt in the face, and asked it what it was. This courage was reserved for those who thought and wrote in our language. Of all the men of the XVIIIth Century, the one perhaps whose heart was most free from scepticism, and whose understanding was most prone to it, was Bishop Berkeley. Other men said

they had no assurance that any thing existed save that which their senses told them of. The thought presented itself strongly to his mind—and what assurance have I of that? How do I know that any of these things which I see, taste, or handle, actually are? A Cartesian might of course answer, “they are because I think them so.” But how can a believer in Locke find an answer? Certain impressions and notions are derived to me from these objects. Those notions and impressions indeed I have; them I can call my own. But is it not a delusion to say that these impressions which I have about things, these notions of them which are stamped upon my mind, prove the fact of outward existence? My senses report to me of a thing that it is green or white, and this greenness or whiteness, according to the oldest theories of vision, is just as much in the eye of the beholder as in the things themselves. But my senses cannot be shown to have any capacity of reporting to me a notion of existence. This surely is a thing which the eyes and the ears take no account of, and yet it ought to come from the senses, seeing it can come from no other quarter. Is it not then more natural, more consistent with the doctrine of Locke, however far it may seem from his actual conclusions, to say I impute this reality to the things around me; they have it not in themselves, they derive it from me? But if so, where is the ground of your denial of invisible things? The difficulty is not in believing them, but in believing the visible. Is it not rather the only way of understanding how those outward things get their reality to believe that we are real, and that our thoughts have to do with realities which we cannot see. In this strange way did Berkeley convert the objective philosophy of Locke into a purely subjective one; in this way did he make the very witness of our senses an argument against the reality of the things which they speak of. His book is one of the steps towards a new era in philosophy. We must therefore say a few words upon it. In the first place, we expect the reader at once and for ever to dismiss the notion from his mind that Berkeley was an unpractical man because he adopted this opinion. Every part of his life is a contradiction to such a notion. Instead of troubling himself only about the spiritual wants of his parish or his diocese, is he not anxious about the coughs and gout and rheumatisms of every poor man in it; and does not he invent a preparation of tar water for the purpose of curing them? Does this look like an idealist? Did ever any materialist give stronger evidence than he did of the most earnest interest in the physical and animal wants of humanity? Secondly, we require him entirely to reject the notion that Berkeley was merely starting an ingenious hypothesis for the sake of showing how much could be said on behalf of it. No one can read a page of his writings without believing in his entire simplicity and sincerity; and we should add, that few persons can have any great experience of the workings of their own minds, without feeling that he is actually stating a difficulty (and that in the clearest, truest manner) which has been presented to themselves. But thirdly, we do not require them to throw aside any belief which they really possess concerning the reality of the things which they see and handle. We do not even deny them the benefit of Dr. Johnson’s practical argument. They are, we conceive, fully entitled to use it, and to receive from it such confirmation as they want of a truth, which we believe it is very important that they should hold.

Idealism.

Berkeley’s
practical
wisdom and
sincerity.

The denial
of the visi-
ble no help
to a belief
in the in-
visible.

Fourthly, so far from agreeing with Berkeley that we gain any thing of faith in invisible realities by denying the reality of things visible, we cannot for ourselves understand how, by any consistent reasoning, a person who has adopted this theory can save himself from the disbelief of all substance, all reality in any thing but in the processes and operations of his own mind. By any consistent reasoning we say, for it is notorious that Berkeley was saved from this, that he did with the strongest faith acknowledge those truths of which his mind only could take cognizance to be above his mind and distinct from it. The result of these remarks is, that if we cannot affirm Berkeley to have made any positive addition to our store of realized facts respecting the perceptions and powers of man, yet that by fairly and honestly stating the difficulties of his own mind, with the purpose not of weakening men’s faith but of strengthening it, he has brought things to such a pass that some results will inevitably follow—some discoveries will be made, and perhaps a new method of thought which will remove some of the confusions, but not supersede the actual principles ascertained by the old one.

These hopes may at first seem rather baffled than confirmed by the labours of the next conspicuous workman in the philosophical field. This was *David Hume*—the name which we inevitably associate with the last possible, nay with an almost inconceivable and transcendent degree of scepticism. But here lay its advantage, it was inconceivable and transcendent. Hume lived amidst institutions which he had no wish to subvert; amidst a state of society which, whether good or evil, was about as good as he could wish or hope to make it. He consequently was not checked in any of his private speculations by the consideration of what would or would not serve particular aims and ends of destruction. He had a singularly quiet even temper, no strong dislike to any thing, but earnest feeling; no strong partiality for any thing, except perhaps for the Stuart family, partly because they were hateful to the Covenanters, partly it is to be hoped from some relics of national and traditional feeling. He had with this a clear and subtle understanding, which being undisturbed by those fears and hopes which in other men perplex its workings, could follow out its own conclusions whithersoever they might lead. Of inward questionings he knew so little, that he could look at every thing as a fair subject for questioning, without feeling that he was any wise concerned in the process or in the result. To this man it was given to see more clearly than any that had preceded him whither the course of inquiries which had been proceeding since the time of Bacon naturally led. Bacon had said, it is by a process of experiment that you attain to a knowledge of that which each thing is. From that time forth men had betaken themselves to experiments upon nature, upon themselves, upon the grounds of both. That the experiments were not without results we have taken pains to prove. That some of them seemed to point to a ground higher than any to which they reached we have intimated. Still it had been assumed, and the assumption gained fresh strength every day, that all which could be known was to be discovered thus; that for a man to talk of there being any thing beside that which he has experience of is vanity and delusion. In the primary proposition of Descartes respecting the certainty of our own thoughts, this feeling was latent, though that opinion seemed to lead him to a very different conclusion; when his notion of innate

sical Phi-
losophy.

thoughts was exposed by Locke, the principle became more developed. Sensible experience became more and more acknowledged as the criterion of truth. The doctrines of Hutcheson, of Butler, and Berkeley, though they might affect some previous conclusions, still seemed to move in the same line. They all referred to certain experiences in man, and appeared to make these the tests of what is true. Hume then did but interpret a feeling that had been consciously or secretly at work before, when he said, "By this experience and by this alone we ascertain what is true." That which accords with the result of this experience we know to be real; that which dissents from it, at all events can never establish itself to us by any evidence.

Denial of
miracles.

The applications of this principle are tolerably well known. The two which are best known are indeed the key to all the rest, so that a short notice of them, and of the answers that have been made to them in England and Scotland, gives in fact a satisfactory view of Hume and his philosophical position. First, experience being the only standard by which we can try any fact which is submitted to us, it is impossible for man to believe in a miracle. No testimony can establish it. The testimony must itself be referred to the standard of experience. If it asserts something which lies beyond the bounds of experience, it cannot make itself good to us. It lies within the bounds of experience that the most respectable witness should be deceived, or even should utter a wilful falsehood. You are bound, therefore, to adopt that solution of the difficulty rather than the other which is self-contradictory. We need not repeat Paley's answer to this objection. It turns, as our readers are aware, upon three considerations: one the equivocal meaning of the word experience, which may be so extended as to exclude the belief of any fact to which we have seen nothing analogous; secondly, on the allegation that experience is outraged by the disbelief of testimony under certain circumstances and conditions; thirdly, on the probability that a divine being would on certain occasions violate the ordinary course of experience for the sake of making important truths evident to his creatures. All these arguments seem to us to have great value in themselves, but not to be adequate to the confutation of Hume. There may be a tendency in his doctrine to make each man's observation nearly the standard of his belief, and so to justify the indignant scepticism of the savage respecting the existence of snow. We are satisfied it has this tendency; but then show us some other standard less limited than this to which we may appeal.

Denial of
cause.

Again, it may be most true that the worth of testimony is necessarily shaken by this hypothesis, and that it drives us to conclusions the most painful to our own minds, and even, if you will, the most contradictory to probabilities. Still if there is nothing in our minds which answers to this testimony, is it not still a question between improbability and impossibility? The last appeal to the will of God carries us on to another ground, but then this is a ground which Hume's second proposition cuts from under our feet. For this is, that experience being the only measure to which we can refer the idea of a Cause is absolutely unattainable by us. A series of antecedents and consequents is all that our experience brings us acquainted with; to this series every thing must be referred. To impute efficiency to the first of a series is a mere gratuitous assumption. Here is the formula of Atheism, one not now for the first time promulgated; in a sense it may be said a very old formula

indeed, but brought out in this XVIIIth Century as the final result to which all human inquiries, thoughts, experiences, had been tending and in which they were to terminate. Against such a formula, Paley might try to bring his natural theology, feeling that all nature spoke of a designer. Unquestionably the feeling was of great worth. He said truly, that it was in him, and had been in all men. But he had to show against Hume, that he did not get the feeling from old religions, nay mainly from that very Christianity which he hoped to confirm by the help of it. He had to show that he really and honestly deduced the idea of a Will from that nature which seems to speak only of succession.

We are inclined therefore to think that the effort of Beattie, Hume's countryman, *Beattie*, against this scepticism was on the whole a more plausible one. He appealed to the Common Sense of mankind. He said there has been a general testimony in favour of these truths. They actually have been held; surely this is an argument that there cannot be any thing in human nature which formally repudiates them. Such a notion we conceive had a certain value in it, but more we think by what it suggests than by any thing that it actually makes known. It suggests the thought—What does this common sense of mankind mean? How do such high and extraordinary thoughts become in any sense the property of a race? How is it that common men can embrace them, and that it should require the wit of philosophers to show they are not tenable? This was a most important thought, one which might well set men on very earnest meditations, and which was connected with many movements that were about to take place. But Beattie's doctrine, looked at on another side, is rather a sop to inquiry than a satisfaction of it. It leaves the alleged impossibility just where it was, and only adds to it the additional marvel which Hume in his *Natural History of religion* had undertaken to clear up—how men could have been brought into the united acknowledgment of something of which they had no real witness. And there was a worse effect of this plausible doctrine, that it brought down thoughts, which either mean nothing, or have the deepest of all meanings, to the most superficial of all tests. The belief of principles respecting ourselves and God was to be supported upon the same ground as some custom or fashion which had lasted too long to be abolished.

Far more importance is to be attached to the doctrine of another Scotchman, *Reid*. His opinions under one form or another, through his own writings, or through his eminent disciple, Dugald Stewart, have obtained a considerable influence over the mind of England, the causes of which it is worth while to investigate. This may be briefly described as the school which endeavours to remove the difficulties Hume raised by enlarging the notion attached to the word Experience. Outward sensible experience seems to be all that Hume intends by the word. Inward Experience or Consciousness is that which Reid superadds to this as one of the grounds upon which our judgments are to be regulated. Now our readers must perceive at once that there is nothing new in this doctrine, that Descartes was at least as great a witness in favour of Consciousness and its authority as any Scotch schoolman of the XVIIIth Century could be. But philosophy, as we have often maintained, is either a reflection of the feeling of the time, or a prelude to some change which is about to take place in it.

Effects of
a religious
movement
upon phi-
losophy.

About the time in which Reid's system began to be proclaimed, a very strong reaction had taken place both in England and Scotland against that formal and natural theology which we spoke of as characterising the beginning of the XVIIIth Century. Other and deeper principles and feelings connected with this reaction we shall have hereafter to notice. One indication of it especially concerns us here. Dogmatic announcements of what it behoved men to do, or to think and profess, had formed the substance of the teaching hitherto. All reference to the feelings and conflicts within the heart had been omitted. The new tendency was, as might be expected, vehemently in the opposite direction; that which a man feels, knows, experiences in himself, was the subject of which all the more lively and popular divinity began to treat. A deep craving there was for that which should explain to men the workings in their own selves, which should deal with their own consciousnesses and consciences. Such cravings might seem to have very little connection with the speculations which were going on in the schools of philosophy. In one sense they had no connection with each other. Now more than at any former time there was a severance between religion and philosophy, and the new religious teachers especially were regarded by the philosophers with a pity and indifference which they fully returned. Nevertheless the strongest impulses that are at work in a time unconsciously affect all those who are living in it; and these Scotchmen, who perhaps less than any others would have liked to confess such an influence, gave the strongest tokens in the character of their doctrines, that they were subject to it.

But it must be confessed, that whether the appeal was made to internal or external experience, no position had been yet taken up from which Hume's conclusions could be effectually assailed. Every one of these attacks upon them was a witness that men could not yield to such complete and absolute scepticism. That religious movement of which we spoke was a declaration of the heart and spirit of men against it. Still it had a resting place in the understanding, and so many of all the notions and habits of the day in England and France seemed to be in accordance with it, that no one could say how soon it might come forth from that resting place, and make itself practically felt. It surely would be most satisfactory to see wherein its falsehood consists, and to see at the same time the ground of its plausibility. And if the experiment, (for an experiment it must be,) by which this point is ascertained, could be conducted by some perfectly fair unprejudiced person, living apart from the influences by which Hume or his adversaries were affected, not open to the suspicion of any religious or ecclesiastical bias, not substituting any ancient methods or notions for those of his own day, avoiding every thing which could be construed by the severest logician into an illusion of the fancy, we might regard it as a most providential circumstance. It is our belief, that a citizen of that nation which had already produced Leibnitz combined these qualities, effectually asserted the principle which was needed to confute Hume, and by doing so added the last to the series of facts of which Locke had announced the first. From what we have said of German philosophy as it was left by Leibnitz, it will be evident to our readers that it was proceeding in quite a different direction from the English and French philosophy of the same periods. Its character was, as we said, even more mathematical and subjective

VOL. II.

than that of Descartes had been. This tone had been preserved among the disciples of Leibnitz. A very eminent thinker, *Wolf* of Breslau, followed in his train. He did not adopt the grand scheme of Leibnitz concerning Monads and the Harmony of the world, and on Wolf that very account he gave a more decided emphasis to the other parts of his creed. The *Theodicaea* was, as we have seen, an attempt to reconcile the understanding with revelation. Wolf appears to have thought that all the principles of morals and metaphysics, nay the principles of all sciences, lie in the understanding, and may be deduced from it. He considered it possible to construct a complete scheme of ethics and philosophy from the data supplied by the mind itself. Probably no man had arisen since the middle ages who had so many features in common with the schoolmen. He differed from them, because he, like every philosopher since the Reformation, was consciously studying his own powers and perceptions, and not merely contemplating them as involved in the general science of Being. But in his resolute adherence to *a priori* dogmas rather than to the deductions of experience, he caught their likeness even while he wandered furthest from their positive conclusions.

The fact that a philosopher of this kind was the one Kant, who exercised most influence in Germany at the time when *Emmanuel Kant* appeared, ought to be well taken notice of by the English student. For he is apt to fancy that the critical philosophy of that great man was a scheme merely set up in opposition to the school of experience which prevailed in England, in Scotland, and in France. This is far from being the case. The studies of Kant were directed quite as much to the object of vindicating a domain for Experience, as of showing into what region its authority does not extend. We have seen that since Logic lost its supreme authority, another science, the one which is the great instrument in all physical studies, had been assuming importance in the speculations of one large and profound class of thinkers. Mathematics had been felt as at once the witness for our need of certainty, and as the means of attaining it. It was evident to a careful observer of the course of speculation during the last century and a half, that this science was the great staff of the *a priori* thinkers—of those we mean who sought for the grounds of knowledge in themselves—while the facts and appearances of nature were the foundation of all teaching in the other school. Kant's first important position then was a severe blow to the Cartesian and Leibnitzian school. Mathematics, he said, like logic, embody forms of our own minds; the one expresses the forms under which the outward world presents itself to us, the other the forms under which the understanding conceives and generalizes the sensible impressions that are submitted to it. Space and time are the forms under which outward things reveal themselves to us; the conditions and categories of logic those under which we judge and discourse of things. But yet it is obvious that mathematics and logic do connect themselves, and have been always felt to connect themselves, with different parts of our being. The line and method of thought into which they conduct us are most distinct from each other, oftentimes one would say most opposite. It is equally certain that the organ of mathematics must be distinguished from the organs of sense, to which it serves as a handmaid, and acts as a corrector. Is it not evident then that here are two distinct faculties—one the

Metaphy-
sical Phi-
losophy.

abstracting, generalizing, logical faculty, the other the properly mathematical faculty, that whereby we are able to take account of the conditions and forms under which the things exist that our senses report of? Would it not be well to restrict to the first the name of *Understanding*, and to find another name for the second, both being evidently powers or faculties of the mind? In asserting this distinction, Kant was asserting the freedom of experimental observation. He was contending that it should not be confined by mathematical fetters any more than by logical fetters; that we see things under certain conditions, just as we form our judgments under certain conditions; but that we are not to impute those conditions to the things that we see any more than we are to impute the conditions of our own judgments, our theories and classifications, to them as the schoolmen did. So far it will be admitted that Kant was strictly Baconian. He was in fact carrying out the very principle which Bacon asserted.

How he
asserted the
existence
of prin-
ciples an-
terior to
experience.

But while we have thus been defending the cause of experience against those who impugn its verdicts, what have we been compelled to say? We have been compelled to assume that there is some organ in us which has to do neither with the beholding of things nor with the merely abstracting and reducing them under heads, one which does not deal with facts submitted to experience, but affirms principles antecedent to experience. There is no distinction between the mathematical organ and the logical organ, unless we admit this. But if this be the case, if there be this capacity of acknowledging data which experience has not supplied, Hume's positions are at all events most unstable. Leaving all the results of them out of the question, treating the matter as dryly, hardly, formally as you can, we have been obliged to recognise some faculty in us which looks straightly and directly at principles not derived from experience, but at principles which surpass experience and regulate it. You say; but this has merely reference to certain mathematical forms, to the possibilities and conditions of things, not to realities. Most true; it has been our object to show this very thing, that this faculty of which we have been speaking does only deal with conditions and possibilities. But if even in things sensible, in things notoriously and confessedly submitted to the eyes and ears, we require some faculty to tell us principles antecedent to experience, who shall dare affirm that all the witnesses which men's minds have borne to principles and objects which are either nothing or most real, are false because they cannot be referred to the rules which experience supplies? You require us to bring the belief of a Cause, of our own Freedom, of our Immortality to some sensible standard. But there is no such thing as a sensible standard. The very facts of sense appeal to another standard. They must be tried by laws antecedent to experience. Which then is most wise, most accordant with the facts of experience, with the actual history of the world, to believe that these ideas of God, of our own freedom, of our immortality, have been established in the world by a succession of frauds and impostures upon the fears of men—to believe that they have been obtained by some laborious generalizations and deductions from outward nature, or from the laws of our own mind—or to believe that, as there is a faculty, which even in matters of sense affirms principles antecedent to sense, so there is a corresponding faculty affirming these great realities, a *Practical Reason*, as the other is a *Speculative Reason*?

The spe-
culative
and prac-
tical Rea-
son.

You say that all demonstrations of the being of God or immortality have been ineffectual. True, they have been so, and you see why they must have been so. It was not by the logical faculty that such truths ever could be arrived at. The plausibility of such arguments and demonstrations, whether deduced *à posteriori* from nature, or *à priori* from the human understanding, lay in this, that there was a higher witness of them present within all of us. We impute its testimony to the arguments, and so make them valid, when, in truth, according to any conditions of the understanding, they are not valid. Let them all be shaken to pieces, but let those who shake them explain whence the faith in them was derived, and say whether this faith be not a greater confirmation of them than the demonstrations would have been if they had been ever so solid and clear.

Such were the conclusions at which Kant arrived by a process of thought and reasoning certainly as severe, as little affected by any influences from the imagination, as little determined in one direction or another by reverence of authority or dread of consequences, as any that were ever followed by any thinker in the world. To adopt them in their fullest extent is not to avow ourselves Kantists, either in a sense which sets at nought the labours of previous inquirers, or in one which supposes him to have constructed a great philosophical system. We have shown our readers how we can recognise Locke as the assertor of an important truth, the remover of some confusions, and the originator of a line of inquiries, without being Lockites, nay while professing the strongest dissent from those who call themselves by that name, and while believing their master to have narrowed most grievously the limits of human belief. In like manner we could acknowledge that Leibnitz maintained a most important truth consequent upon and connected with Locke's, while yet the theory or system which he strove to ground upon it seems to us of comparatively little worth. And generally, in reference to all the thinkers of this period, we have contended that just so far as they were occupied in the search after human powers and perceptions they were proceeding in a profitable course; that just so far as they were attempting to set forth the objects upon which these powers were to exercise themselves, or to deduce any theory from the existence of these powers, they were going beyond their province, and attempting what they could not perform. At all events, therefore, we are consistent in applying this distinction to Kant. We hold that he alleged the most serious grounds for believing in the existence of faculties which had not been recognised by any of those inquirers who, since the time of Bacon, had devoted themselves to the examination of man's nature and to a comparison of it with other natures. We hold that this discovery, so far from setting at nought those which we owe to Leibnitz, Hutcheson, or Butler, illustrated and confirmed them, enabling us to see a warrant for their language which they could not see, and relieving it of many confusions and embarrassments. We think further, that Kant's principle throws back the greatest light on Berkeley's Idealism, Hume's Scepticism, Beattie's Common Sense, and Reid's Instinct; showing why Berkeley was driven to rest satisfied with the impressions on his own mind, and so to doubt the evidence of his senses, just because he did not feel that there was a power in that mind which had to do with invisible laws and realities, as those senses have to do with what is visible; how Hume was led to outrage the

conclusions of experience, because he could acknowledge nothing besides experience; how truly there must be a Common Sense in mankind respecting that which has not to do with outward experience, if the Practical Reason be indeed the great common inheritance of all, and yet how certainly that witness is not one lying on the surface of our minds, and capable of abetting all the fantastic conclusions which may have mingled themselves with deep truths through sensible idolatries, and ill understood experiences; but the deepest thing of all, testifying of that which is the most pure and necessary, and absolute; how certainly there must be high Instincts and Consciousnesses in the mind, but how they point to a ground above all instincts and consciousnesses to that which is most constant and permanent. But we hold at the same time that *Kantism*, or the attempt to build upon this doctrine of a practical and speculative reason, has inevitably led to the loss of all these good consequences, to the denial of that which other men had established, to the practical renewal in their worst form of all those confusions from which the Critical Philosophy, properly used, may be the deliverance. Our meaning is this. It was, as we have seen, part of Kant's object to set men free from the bondage to certain Forms which had taken the place of or else mingled themselves with those logical forms by which men had been enslaved in the scholastic ages. To accomplish this object, he was obliged to use language in which there lurks at least a possibility of much perplexity. He was obliged to say, "Space and Time are forms of our own mind."

Perversion
of his doc-
trine to the
denial of
other men's
facts and
the con-
fusion of
his own.

When he explained himself, it was quite evident that this assertion implied something very different from the corresponding one, that the forms of logic are forms of our own mind. By logic we compare different words and notions which are presented to us. The laws then which the understanding takes notice of are expressly and strictly its own laws; the laws which the reason takes notice of can only be considered as the laws which determine the relation between it and external things. We may therefore say, and we conceive ought to say, that Space and Time are the laws of nature just as much as that they are the forms of the speculative reason. We do not express the whole truth, except we resort to both these modes of speech. It does not lie in either, but it lies between them both. Space and time are not in nature as actual objects; to suppose this is to confuse all our experimental studies. But on the other hand, if we do not speak of them as being presented to us as well as existing in us, we shall unquestionably lose the very distinction which Kant realized, confound the forms of the reason with the forms of the understanding, and make them as tyrannical and dangerous as ever the others had been. Now to what extent Kant devised a nomenclature which could guard against this evil in respect to the speculative reason, and how far, if he did, his disciples have profited by it, we shall not stop to inquire. But the corresponding danger with respect to the Practical Reason many of them certainly have not avoided, and we believe while they consider Kant as their exclusive teacher they cannot avoid. As Kant said that the forms or laws of the external world were in the speculative reason, so he said that the ideas of freedom, of immortality, of God, are in the practical reason. In what sense such language may be used, without danger or irreverence, we endeavoured to explain when we were speaking of the Platonic philosophy. But it is quite obvious that the peril in the case of Kant is

much greater than in the case of Plato. Plato was not investigating the nature of a faculty. He was considering under what form truths present themselves to us, so that they may be at once our own and not our own, that we may recognise their self-existence, and yet feel that we possess them. The mischief to be guarded against was constantly present to the mind of the Greek. His doctrine of ideas was the strange, and to a person who had not felt the confusion, the incomprehensible and contradictory language by which he escaped from it. With Kant it was far otherwise. He was asserting distinctly and formally the existence of a certain faculty, and he was to define the nature and the limits of that faculty. How easily then might he slide into expressions which signified, if not to his own mind, at least to that of eager disciples who looked upon him as the great prophet of the world, that these truths are actually embodied in the reason; that all notion of them as objective truths presented to us has been once and for ever confuted; that all revelations pretending so to present them are merely the delivery, in confused forms suitable to vulgar apprehensions, of that which was already in us beforehand, which sages of old knew perfectly well, and which modern sages are to separate from all their inconvenient drapery, and exhibit so far as opportunity and prudence permit in their naked and original simplicity. The true answer to such notions, we conceive, will be found in a calm and clear explanation of Kant's doctrine, and of the steps by which he was led into it. We shall then see that any view of the reason which does not make it a Faculty of Apprehension and Converse, which does not suppose it to require objects, and to have its life only in the beholding of them, destroys its nature and definition. It will then be felt and understood, that the discoverer of such a faculty did not by discovering it make us better acquainted than we were before with the Objects upon which it is exercised; that he may not have been the least qualified to throw any light upon that matter, and yet that he may have been doing the greatest service by showing that those Objects are not addressing themselves to creatures with no capacity for comprehending them, but to a being whose deepest necessities are unsatisfied, whose deepest powers are unexercised till he can recognise them.

The metaphysical philosophy of this period (so far as it appertains to the nature of our perceptions or knowledge) had now reached the highest point which it was capable of reaching, and at that point had become mixed with the most important moral principles. It had also reached a point at which school philosophy became obviously connected with human life. The laws of the human understanding, and even the maxims of experience, may belong to learned men. The demonstrations about Being and Will had little to do with the multitude. But if Kant's doctrine be true, that there is that in every man, which not by slow processes of proof, but directly, testifies of the most absolute and essential verities, the whole race was interested in that as a fact which as a speculation belonged only to the few. Many other contemporaneous events indicated that a crisis was approaching when the deepest principles would be found to have the closest and most vital connection with the movements of men of whom philosophers knew nothing, and from whom, by their idolatry of their own peculiar gifts and methods of knowledge, they are often as widely separated as the worldly great by their idolatry of fortune and fashion. Something of this might be traced

in the kind of theories about this time coming into vogue in regions which German metaphysics had not penetrated. It was not strange to see the chosen friend of David Hume devoting himself to so purely experimental and objective a study as the *Wealth of Nations*. But it was somewhat prophetic of the approaching time, that he should set forth the feeling of *sympathy* as one of the leading principles of human nature, which accounted for that marvellous tendency to combine and associate discoverable among men, and for the action and reaction of huge masses upon each other—facts which would indeed soon require all the wits of all the philosophers to expound them. It was not an uninteresting or unimportant circumstance, that a friend of Adam Smith, nearly the greatest man of this age, *Edmund Burke*, began his remarkable career with a parody of Bolingbroke, teaching how the principles which philosophical aristocrats had advocated respecting natural *religion*, and its superior value to every thing revealed, might lead humbler folks to prefer natural *society* to that which gave titles and seignories. The step from the prophecy to the fulfilment, from the pretended vindication of natural society to the actual vindication of it by Jean Jacques Rousseau, is not long, but it is filled up with some facts which we must take notice of as most important in the illustration of philosophical opinions as well as of their relation to the history of mankind.

The great question of this age had turned upon the relation between human nature and other natures. Thus we must for the present express the question, though the language is not that which we might ourselves prefer, because, as we stated before, the point at issue really was whether man is or is not a *super-natural* creature. If we believe Kant's decision to be right, that man has a reason which is capable of conversing with that which is transcendent and absolute; we shall consider that, in reference to his capacities of *knowing* at least, this question was settled in the opposite way to that in which Hobbes had settled it. But there was another denial of Hobbes which had been felt by all men, by all religious men especially, to touch the vitals of truth even more nearly than this. He had denied man a *will*. He had taught that he is subject to the same kind of necessity as all other creatures. Hobbes believed himself—all his opponents believed—that in this principle his other conclusions were involved. Neither he nor they could understand what a scheme to redeem man could mean; what the idea of an intercourse between man and his Maker could mean if the fact were once established, "Man neither actually is nor is intended to be any thing but the obedient subject of certain motives or influences external to himself." But we have seen how strangely religious men had suffered the ideas of nature and God to mingle together in their speculations, and how deeply the habit of confounding them had worked itself into the mind of this age. It is not, therefore, matter of wonder that a man should have arisen, of strong logical power, and of great moral excellence, who proposed to himself the task of constructing a scheme of Christianity from which the idea of a Will should be formally banished. We use this language advisedly in speaking of *Jonathan Edwards* the American philosopher. For it is not true, as he and some of his admirers pretend, that he was merely reasserting in a more logical form the doctrine of Augustine, or at least the doctrine of Calvin. Between the principles of Augustine and those of Edwards there is a distance actually impassable;

nor do we believe that the Helvetian reformer would have protested much less vehemently than the African bishop against this supposed reproduction of his opinions. The redemption of the will out of its slavery to nature—including under the term nature all influences and motives whatsoever which prevent it from enjoying the perfect freedom of intercourse with, and subjection to the divine will—was the end which Augustine recognised in all the interferences of God on behalf of his creatures. Calvin may, no doubt, have sympathized more in that part of his writings which asserted the absolute power and dominion of the divine will over the human, than in that which spoke of its own cries for deliverance. But we do not think that even for a moment he conceived the subjection to a set of external motives, which Edwards spoke of as the proper condition and constitution of the human Will, was otherwise than the badge and proof of its bondage. We have a right then to say, that this theory, when connected with Christianity, was a new one; that it was an attempt to make the principles of Hobbes support a creed which he, on account of these principles, rejected. We are quite aware that Edwards rejected with indignation the idea of a natural law as governing human actions, and that his disciples believe him to have relieved the question of all its difficulties by introducing the phrase *Moral Necessity*. Our statement of his opinions will not, however, be disputed. He does treat man as properly and by constitution subject to a certain set of motives, let these motives be called by whatever name they may. Edwards does not believe that he is intended for freedom, or that freedom, in reference to him, means any thing. And this proposition his followers say that he made good by the most irresistible logic. We believe them just as we believe that by a train of logic equally irresistible Hume proved that there can be no Cause. Once admit that there is nothing above logic, once agree to deny the idea of a mystery which man owns, though his understanding cannot comprehend it, and we acknowledge that the belief both in a divine Cause and in a human Will must disappear. But it cannot disappear: that very Will which your logic has proved not to exist rushes in and tears its conclusions to atoms, and that Being of whom your logic can take no account demonstrates his own reality. Of such confutations of theories by facts we are about to speak; in the mean time let us do homage to the thorough honesty of Edwards's mind, an honesty which, though shown in following his premises to their actual conclusions, is shown also far more satisfactorily in surmounting these conclusions, and in penetrating into regions which they could have never led him. He speaks of Religious Affections as one who had them, and who could not therefore really assent to mere conclusions of the understanding, and he describes *The Being* as the end of all desires and contemplations in language familiar to Platonists, but which to the majority of his disciples must be utterly incomprehensible.

One would have thought that the events which were connected with the appearance of the Methodists in England, Scotland, and even in America, events which no doubt interested Edwards beyond all others, would have been enough to demolish his hypothesis; for surely their preaching was an appeal to the Will which lay deep in the peasants of these lands, and by that Will it was answered. That it could not have come forth except it had believed that it was summoned by a Will higher than its own, we are well con-

vinced. That it was the recognition of such will—such a *Spirit* which gave all the worth to this excitement, though, being mixed with confused human and natural notions, it may have given also the particular shape to its superstitions, we are also assured. This was the theological truth which upheld the newly developed sense of a Will in our countrymen, and prevented it from being destructive, as the belief of a Deliverer and Mediator was the theological principle which upheld the newly developed sense of an *Intelligence* at the time of the Reformation, and which prevented that from producing an immediate and universal scepticism. But under whatever condition, it *was* this sense which was stirring here and in all parts of Europe, and which was to prove what reality and might it has either for the highest good or the most fearful ruin.

Conclusion.

And now we are arrived at that great practical experiment which was to confute or establish the logic of Hobbes. Rousseau, the beginner of the new era, proclaimed that the savage state which Hobbes had denounced was the best for man. He proclaimed too the doctrine of a Social Contract with all the pomp and circumstance which Locke had been unable to impart to that theory. A whole nation was roused by such words from its slumber. The principle of savage life, the right of each individual man separate from his fellows, was asserted; governments were built upon this foundation, and fell to the ground; at last the strongest man prevailed and despotism followed. Were not the positions of Hobbes demonstrated? Assuredly, so far as this they were demonstrated. It was shown that man cannot exist out of society, that it is a dream to think of his existing out of it, that he must be held by some other bonds than by the imagination of a Social Compact. But in the mean time it *had* been proved that man has a *Reason* and a *Will*. A *reason* which, if it has not some absolute infinite object to satisfy it, will strive to make the finite infinite, to deal with facts of experience as if they were absolute truths, reconstructing a nation or a universe upon a theory—a *will* which must either acknowledge the mysterious government of a will higher than its own, or must work the confusion which Hobbes fancied in his dream that a human despotism could restrain. These were conditions which Hobbes had not taken account of. What result should they have upon our minds? Do they not seem to show that Society itself is a transcendent thing, that it cannot dispose itself according to any accidents and conventions, that its foundations lie where Plato fancied that they lie, and that every particular society which does not do homage to some universal society based upon a deeper ground than itself, is doomed to inevitable destruction? If this be so, then we may believe that those two lines of thought which began to diverge after the time of Bacon, those which we called the political and mathematical lines, have found their meeting point. Kant's discovery of a Reason in man is the termination of one line, and the discovery that a Society is necessary which deals with that Will and Reason as supernatural faculties, is the termination of the other. Still there was a third line of thought which has been running on beside these two through all these centuries. From the time of the Reformation we saw men beginning to feel the necessity of another and more human form of morality than that ideal morality which had belonged to the middle ages, or that transcendent form of Christian devotion which had characterised the age of the Fathers. We have seen men at a loss to understand what this

lower morality might be, resolving it into pure selfishness with Bossuet, treating it as mere Manners and Conduct with the Englishmen at the beginning of the XVIIIth Century. Yet it must be more than this, for Butler in that very time found that we had a Conscience, and he said also that we had *Social Affections*. May not these Social Affections be the link between the lower and the higher morality, not perhaps being separated by any wide chasm from those *religious* affections of which Edwards spoke? The reformers we remember discovered in our human relationships more than the symbols of a relationship between man and his Creator; they said that through the fulfilment of one he ascends to the knowledge of the other. If this were the case, we can better understand why the assertion of a solitary individual existence in France was connected with the denial of any relation to God, and why the Universal Society which the reason and will of man seem to require, must be one which is not merely Platonic, not merely based on Absolute Truths, but united with all Family Relationships, and with the distinct ordinances of National Life.

We have not scrupled to enter upon topics of this kind in a sketch of moral and metaphysical inquiries, because we know no other way in which we can so effectually prove that these inquiries have reference to realities and not to dreams, and that they have not been conducted in vain, but have led to results which are confirmed by as certain evidence, and are at least as important to the welfare of the human race as any that physical science can boast of. When we set down a number of warring opinions as the dogmas of particular thinkers or sects, we are easily led to believe that there is no moral Science, that all manner of questions have been discussed, and that nothing has been proved. But when we connect together the speculations of different periods, and mark how they bore upon the events transacted in these periods, we acquire a far more cheerful and hopeful feeling. Then it seems evident that no earnest thinker has lived in vain, that the conclusions of no age have been ultimately superseded or displaced by that of the one which has succeeded it. We find that in every time principles have been submitted to the severest discipline of opposing feelings, notions, and passions, of unwise and dishonest advocates, of cruel persecutors and dangerous patrons. We find that they have been overlaid with theories and schemes the most fantastical and incongruous—that they have been applied to cases to which they had no relation—that they have been distorted till they became curses instead of blessings, and yet we have seen them coming out of this ordeal only clearer, brighter, and stronger. This being the case, we cannot but account that doctrine a most narrow one, injurious to man, and blasphemous against God, whatever pretences of enlightenment or piety it may put in, which would disparage any portion of the world's history. Whether it assume the form of a reverence for the Past or the Present, whether it lead us to think that no light or wisdom has been vouchsafed to men in later days, or that all light and wisdom are with us, and that our fathers either dwelt in utter darkness, or were only catching a few glimpses of truth which we possess in clearness and fulness, we think it is equally at variance with the witness of our own consciences, the evidence of

history, and the promises of revelation. Nay, we believe, in both cases, such an opinion operates against the reverence which it pretends to encourage. The feeling that we are hopelessly incapable of thinking and feeling for ourselves destroys all affectionate sympathy with those who came before us, causes us to regard them with fear and prostration of spirit, not with cordial admiration; as harsh pedagogues, not as friendly teachers. The habit of believing that the concentrated essence of spiritual and moral truths is contained in the speculations of our own day, makes those speculations an intolerable bondage, stifles all freedom and originality under the pretence of fostering them, and ties us down to transitory notions and modes, while perhaps we are in the very act of boasting that we have thrown off such modes, and have attained to the knowledge of that which is pure and permanent. Against these diseases no remedy, we believe, will be found so effectual as the patient study of history. Many indications seem to point out this as the particular work of the time upon which we have entered. Everywhere men will be found attempting upon some scheme or other to combine and reconcile opinions. Everywhere men will be heard talking about comprehension and universality, till others, disgusted by the hollowness of their language and their practical inconsistencies, strive to shut themselves up in some exclusive circle; but soon experience there the very same impulse, and repeat the experiment in some newer method. Everywhere, we think, it will be seen, that those who are labouring to devise theories and plans of their own exhibit a lamentable want of originality, and that those who spend most labour in studying and recording the doings and thoughts of others, kindle in themselves a true and native spirit. A glance at the progress of thought in the three principal nations of Europe since the French Revolution, will, we believe, confirm this opinion, and may help to show us in what kind of work a student of moral and metaphysical philosophy may now most profitably engage.

It is natural to turn first to Germany as to the country in which the philosophical spirit has most strongly manifested itself. About the time that the critical philosophy was promulgated, the creative powers of the Germans began to be awakened, and a race of eminent Poets and Critics arose in that country. How much this new literature was connected with the use of a native language and the growth of a national feeling we need not stop to explain. Any strong efforts of the imagination must, as we have often had occasion to remark in the course of this sketch, be national, and will generally be observed only at some great national crisis. But it is important to notice wherein this literature mainly differs from any previous European literature. It is characteristically historical and critical, reproducing old forms, bringing back the study of authors and the remembrance of traditions which had been lost, commenting upon the forms of poetry and art generally as manifestations of particular forms of feeling—in all respects acknowledging the past at least as a storehouse of facts and images. Whether this kind of writing may not ultimately have cultivated that idolatry of this age which it seems to be resisting; whether the great men of Germany may not have felt, that they who could look back upon past ages, and take note of the peculiar features in each, must needs be superior to all who went before them—that the faculty of criticism is the great faculty of all, and that he who can

use it is more wonderful than he who possessed the thoughts which are criticised—and whether this feeling may not have communicated itself in a tenfold degree to their disciples and successors, who, if they have none of their creative or their critical power, at least talk of each, till they work themselves into the sense of possessing it, are points upon which we are not qualified to express an opinion, though they are doubtless important for the consideration of Germans themselves. At all events, that effort at comprehension which we spoke of, accompanied with a zealous contemplation of the past, has belonged in a high degree to these German artists, and the systems of philosophy which have grown up during the period in which they flourished, seem to show that the inquiries with which we are more immediately concerned must eventually take the same direction. It is to the object and central point of those systems, not to any of their formal dogmas, that we shall refer. If the reader can allow for the difference between the periods in which they appeared, he may find in *Fichte* and *Schelling* parallels to some of the eminent doctors who divided the schools in the middle ages. The first a noble and earnest spirit, formed in a time of the greatest national excitement, and possessing the strongest national feeling, rose up to assert that the individual, the “I myself,” is the groundwork of all philosophy. He could not find in Kant, or in any other philosopher, a satisfactory recognition of this personality, without which he was sure that life is a dream, and therefore without the confession of which all philosophy must be a dream too. The intense necessity of this feeling we hope our readers will be as ready to recognise as they will the conviction in the mind of Schelling, that the attempt to ground a system upon it is hopeless. The need of an absolute ground of things was that which presented itself to him with as great force as the other thought had presented itself to Fichte, and this need he fancied in like manner that a system might satisfy. We are not obliged to inquire into its nature, seeing that it is said not to be satisfactory to its author. At any rate the want which each system expressed was felt and realized by innumerable minds, who, having felt it, probably became soon dissatisfied with the form wherein it had first made itself known to them. Another amiable and benignant philosopher complained of the harshness and dryness of Kant’s speculations. The heart (said Jacobi) demands satisfaction as well as the reason, and what is there in the critical philosophy which supplies it? Jacobi sought to supply it himself. We are not aware that he succeeded, though if he led others to feel the necessity, he surely did not live in vain, whatever his scheme may have done for them. But the German mind, while fully capable of sympathizing with all these vital principles, has unquestionably a craving after system and order for their own sake. When the tumult of national feelings had subsided, a scheme became popular, which aimed at the most extensive combination and comprehension, not starting from the lowest point, and gradually feeling its way upwards, but beginning from the highest ground, and reducing all the thoughts, speculations, intuitions, projects, expectations, sciences of men, to their proper compartments. This vast doctrine of Hegel alarmed the mind of a deep and earnest thinker, who knew from history how much such grand conceptions had in all ages done to stifle the thoughts and destroy the reality of the feelings which they so skilfully arranged. As we said in our notice of

Plato, his method was in the most direct opposition to all such projects, and only by overthrowing that method can they ever effectually establish themselves. This seems to have been Schleiermacher's opinion. By developing with great clearness and power Plato's method, by distinguishing the faculties which he supposed to be occupied with the different subjects that Hegel's system endeavoured to bring into fellowship, and by cultivating a practical Christianity in the minds of his countrymen, he hoped to deliver them from the mischiefs of an all-embracing theory. Still we believe it is felt in Germany that something is wanting which Schleiermacher did not supply; something which should be a substitute for the Hegelian system, if that must be abandoned as dangerous; some scheme which shall begin as his professes to do from the highest ground, instead of ascending from the lowest. We have already expressed our opinion that Plato, though he always failed and sacrificed his own method when he attempted to construct such a scheme, yet had the deepest feeling that it was necessary. We looked upon the *Timæus* as his awkward endeavour to create a universal system—upon the *Republic*, as a wonderful attempt to discover what system is implied in the actual constitution of things. We ventured to intimate a doubt whether Schleiermacher, with all his knowledge of Plato, had not failed, partly through over ingenuity, partly owing to a disadvantageous position in discovering the meaning of the *Republic*. If he had seen this, and if with his study of the Gentile elements which enter into the composition of the Christian church he had meditated more deeply on its Jewish origin, we believe he might have been able not only to oppose Hegel, but to show that an actual Polity grounded upon an actual Revelation is the only effectual substitute for a circular System grounded upon a philosophical Notion. We cannot, therefore, help listening with the greatest interest to the reports which reach us concerning one of the philosophers of whom we have spoken already; who, it is said, is occupied with considering what there is in our minds which answers to and realizes those ideas which are presented to us in the Scriptures, and are embodied in the creeds of the early church. Not to provide a substitute for these, but to show how they concur with the needs and anticipations of the human spirit, is, we are told, the present purpose of Schelling's meditations. With a full sense of the hazards and temptations which may accompany such an inquiry, we yet believe that it is the most promising and the most truly rational upon which German students have yet entered, the one which gives most hope that philosophy will assert its true position, and will not intrude into a position that was never intended for it. A thinker, who has propounded a system and owned it to be inadequate without losing his hope, has passed through a discipline which promises well for his future inquiries, and we may venture to believe that they could not be better carried on in any part of Germany, than in a neighbourhood which is occupied with an earnest practical discussion between Protestants and Romanists.

Indications
in France.

Ultra-ma-
terialism.

If we turn to France, we shall find tokens of the same character, only the more remarkable for their opposition to the habits of thought which had for so long a time been established in that country. Some appearances there were for a long time after the peace of a tendency to carry on the speculations of the analytical and materialist philosophers further than they had been

carried even during the philosophical tyranny of the XVIIIth Century. But a vigorous, we might say a violent reaction has taken place. The Scotch philosophy of Reid first found its way into the French capital, and began to displace the more ultra Epicurean doctrines; then by degrees German metaphysics also came thither, and were eagerly studied. Translations of Plato, and histories of ancient philosophies, speedily followed, and of late it has been a great ambition with Frenchmen, under the guidance of M. Cousin, to combine together all the systems, or at least fragments from all the systems that have ever existed, and to frame out of them a complete psychological and ontological theory which shall account for the dogmas, as well as for the thoughts, feelings, wishes, and hopes that have been entertained by mankind. We have already expressed our opinion of such projects. We have said that in a great system of Ontology we suspect *Being* will cease to be; that in every comprehensive eclectic psychology you destroy the feeling in order to examine it. Nevertheless the indications that some principle of reconciliation, as well as some kind of system, is necessary, and that our business is rather to recognise the old, than to establish any thing new, are as strong in this case as in the last that we were examining. And the historical feeling in France has not merely wasted itself in attempts to conglomerate different speculations. It has taken another and a much healthier direction. Thoughtful men there have caught the spirit of Montesquieu, have inquired into the meaning and origin of institutions which their fathers despised, have acknowledged the existence of deep thoughts in men whom their fathers believed to be the dupes and slaves of designing priests, and have bowed to the necessity of a deeper wisdom than any which they could refer to particular men in linking together the thoughts of one generation to another, and directing the course and influences of outward events. That this critical spirit is liable to the same danger in France as in Germany—that men there are even more likely to exalt themselves, because they can appreciate the wisdom of their ancestors, as they once exalted themselves for scorning it—that a hollow fashion of reverence for antiquity is likely to take its turn with other fashions, and that there is much in these speculations themselves which leads us to fancy that we are on the highway to an almost perfect state of existence, because the thing or the abstraction called Civilization has been continually in progress, we fully acknowledge. Still we cannot help hoping that good results will ultimately come from a change so very remarkable and unexpected as this, which has taken place against the strongest resistance from all the worst and some of the most powerful elements in the French character.

The first signs that present themselves when we turn to our own country, would seem to betoken a remarkable difference between our state and that of our continental neighbours. A foreigner who should hear that Paley's *Moral Philosophy* was the recognised text-book in one of our Universities, and should inquire what the nature of that book was, would undoubtedly be surprised to learn, that though written by an eminent, and, in many respects, admirable divine, it made the good or evil of an action depend wholly upon its results, and taught in what ways we may arrive at right conduct by calculating those results. A book wholly overlooking or denying the facts which were established in the

XVIIIth Century by different independent thinkers, to say nothing of the principles which were held sacred in earlier ages, would seem to have very little of the comprehensive historical character which has discovered itself in philosophy elsewhere. And indeed it has not. Yet we are by no means anxious to take advantage of the plea, that this book belongs rather to the past age than to the present, or to see in it no indication of the tone which we believe philosophy in the present day must assume if it is to maintain its ground.

Politics and
morals
united.

Paley's is a moral and political philosophy. It deals with morals as related to politics, as being by some link or other inseparably united to them. This we fancy is an important and characteristic difference between it and most of the writings of the XVIIIth Century, even those to which upon other grounds we should attach a much higher value. It is an instance, we think, of that remarkable clearness which accompanied in Paley what we fear must be called a superficial method, and even a superficial habit of mind, that he perceived the necessity of treating morals under its political aspects. It gives him a title to rank with Locke—a person much resembling him in character, though inferior to him in a certain transparency of intellect as the beginner of a new era of study, however differently from his conjectures it might be destined to terminate.

Metaphy-
sics sepa-
rated from
human
interests.

We are strengthened in this view of Paley by comparing him with *Dugald Stewart* and the philosophers of the Scotch school, who for a while held a divided empire with him. This school assumed in Stewart's hands a kind of eclectic character. It professed to deal with the mind upon the principles of Experiment and Induction, and was willing to pay all fitting respect to previous teachers. It took to itself somewhat more credit than it deserved for its principle of Induction, seeing that this was the principle upon which most of the inquirers since the time of Bacon had actually gone, and seeing that Mr. Stewart, though admiring experiment, would tolerate experiments only up to a certain point. As long as they took note of no principles antecedent to experience, external or internal, he admitted their validity. But without attempting to show that Kant had used a less severe method of induction than previous philosophers, without showing wherein his experiments had been fallacious, Mr. Stewart's faith fails him just as he reaches one particular crisis in philosophical inquiry, and he determines that to such strange doctrines as come from Germany he will give no ear. All this would have been very well borne in England, at least for a time, if these Scotch teachers had not laboured to keep their speculations free from any allusion to the actual life and business of men. They were philosophers, and philosophers merely. What had they to do with laws, and governments, and religions? Such matters lay entirely out of their cognizance; they would observe the most rigid silence upon them. Now seeing that they profess to be emphatically the practical philosophers, that they proclaim the schoolmen to be dreamers, and Plato and Kant to deserve no better name; this seems to our English tastes and apprehensions a little puzzling. What means a philosophy, and a practical philosophy too, which has no concern with any thing that we are thinking or caring about—which talks to us indeed about our own instincts and consciousnesses, but leaves us to fancy that these instincts and consciousnesses have no real objects in the heaven above or in the earth beneath. Such speculations might be very good for

creatures of another race, but they seem to be exceedingly unsuitable for toiling human beings.

We cannot wonder then that a philosophy which vigorously applied itself to human objects, should very soon have displaced one which seemed wholly fantastic. Paley was better for us than Stewart. But we could not stop where Paley stops. The scheme of utility was in him mixed with many incongruous elements, and he had followed it out very imperfectly to its consequences. Acknowledging expediency as the only guide in politics as well as in morals, he had yet defended institutions and revered creeds which had clearly not this basis, or are full of the most strange and incongruous materials if they have. Mr. Bentham could endure no such inconsistency. Starting from the one simple hypothesis, that Pleasure and Pain are the ultimate laws of the universe, he determined, not as former Epicureans had done, to invent a scheme of life for himself, but to model society upon that principle. As we have already examined this doctrine in its simple form, we need enter into no fresh discussion respecting this modification of it. Indeed, even if we had not that excuse, the task would now be unnecessary. The scheme of Mr. Bentham was brought forward as the last achievement of the philosophical spirit, the highest possible result of an advanced state of civilization. These phrases which worked most powerfully in its favour have of late been turned with deadly effect against it. Persons as utterly averse as he could be from ancient forms and institutions have attacked him on this express ground, that he has not kept up with the march of knowledge, that he adopted a narrow theory of human nature from a narrow induction, and wanted the capacity for acknowledging the discoveries of those who had taken in a more enlarged sphere of observation. But it has also been represented, we think very unjustly and very injuriously to his reputation, that we can abandon his moral and metaphysical theory, and yet maintain the political deductions from it. Now it seems to us, that one great and deserved cause of Mr. Bentham's popularity was his bold and honest assertion that these cannot be separated. We owe him, we conceive, very great gratitude for overturning the dilettantism which had become fashionable in philosophy, and for showing that the test of principles is their application to practice, and the test of practice its power of being referred back to principles. He was besides a powerful and consistent logician, who might be mistaken in premises, but who in the steps from his premises to his conclusion would very seldom stumble. We are bound, therefore, to consider that his utilitarian philosophy and his theories on practical legislation and politics must stand or fall together. He is, we think, the completest form of the utilitarian philosopher that has ever appeared, or is ever likely to appear. The influence he has exercised upon the times is not wonderful, when we consider either the plausible doctrine which he defended, the confusions in the minds of his opponents, or the real intellectual power and moral earnestness with which he assailed them. The rapid decline of his fame it requires some more words to account for.

The strong political bias of the English mind has been constantly urged as a reason why any deep philosophy must be always uncongenial to it. We have seen what confirmation this opinion seems to receive from the prevalence of Paley's doctrines, and the indifference with which Stewart, in spite of powerful patronage from a powerful body of Scotch friends or disciples, has been

regarded. But we have already hinted our belief that these indications are fallacious, and that wherever practical feelings are most alive, there ultimately, if not immediately, men will be driven to seek for the deepest foundations. In Greece we observed, that the most flourishing times of philosophy were the times of strong political feeling, and that it grew weak as those feelings decayed. We are not ashamed then to confess that we believe the doctrine of expediency which Paley sanctioned might have continued to prevail among us, if men had not been startled by observing to what practical conclusions that doctrine led, when it was fairly and consistently followed out by Bentham. To find plausible arguments against some of these conclusions was easy, to find a strong *vis inertiae* in the public mind which could withstand them was not impossible. But various experiences show, that neither the special pleading of clever men, nor the reluctance to move in comfortable men can be always trusted in an hour of need. Something more than this was wanted, and however imprudent many might deem it to examine the grounds of that which age and custom had made venerable, such an investigation was inevitable. The question was in what spirit should it be undertaken. If carried on at all, it must be carried on not timidly but boldly; the examination must be not partial but complete. But should it be pursued in a spirit of hatred or of love, of contempt or of reverence? The first method has been tried to the utmost by Mr. Bentham and his followers. If it is the most effectual, it should assuredly be persevered in. But a set of persons have arisen to say that it is not effectual; instead of going too far, you have not gone far enough. Instead of judging practices and institutions by tests which are too severe, by principles of human nature which are too deep, you have made use of the most weak tests, you have brought the most shallow principles to bear upon them. We demand a more rigid scrutiny: instead of a few flimsy inductions from a few facts which present themselves on the surface of society in the present day, we must look into history, and study the growth of our institutions, that we may know really what they mean. We must look into the same history to know what men have been thinking about in past ages, that we may see whether this doctrine of Pleasure and Pain is really that in which all other doctrines begin and terminate, or whether it is merely the deposit or scum that is left after all that is strong and vital in human thoughts and feelings has evaporated. To such inquiries men have addressed themselves; some beginning with an aversion from that which afterwards, by slow degrees, they were led to admire; some beginning with a confused sentiment of admiration, as well for institutions as for all the practices of those who administer them; but both agreeing at last in the confession, that the more their sympathies have been awakened for what was truly and permanently good, the more keenly they are able to distinguish between it and any evil innovations which fashion or selfishness may have grafted upon it; the more anxious to remove, though with a delicate and careful hand, all such unnatural excrescences. In this *Encyclopædia* at least, the plan and method of which were originally suggested by Mr. Coleridge, we should be most ungrateful not to own, that of all those who have assisted in imparting this feeling to the English mind, he was incomparably the first in genius, in knowledge, and in moral influence. We are anxious in this

place and in this connection to introduce his name, because the impression has been very widely diffused, both by his enemies and his admirers, that his mind was wholly cast in a foreign mould, and that all which Englishmen hailed or disliked as novel in his writings was already familiar to thoughtful men in Germany. For novelty, no one more eagerly disclaimed it on all occasions than he did. It was his greatest desire to revive and reproduce the old; he left it to the original writers in journals and magazines to supply the public with what is new. He was also most anxious to testify his obligations to the German writers, and that at a time when it was not a credit, but a disgrace to be suspected of any sympathy with them. But that a man who had been educated at an English public school and university, who had entered earnestly and passionately, yet, even in his most extravagant moments, with ardent patriotism, into the questions which agitated the people of England, and had produced his noblest poetry before he entered upon his German studies, should be supposed not to be truly and originally national is most unreasonable. In later life he was in the habit of connecting, even in a forced and unnatural manner, the language of Hooker and our early English divines with that of Kant—as if he felt almost reluctant to receive any thing from abroad which he could not associate with some national feeling or recollection. He did, however, most earnestly assert the truth of Kant's positions, believing that men had been withdrawn from their faith in those transcendent truths which their creeds and institutions embody by the loss (for such he deemed it) of the conviction that they had a faculty within them to which these truths could appeal. But on the one hand, no person was ever more zealous to maintain that the Practical Reason which demands these truths is not the inheritance of philosophers, but of every poor man in the land; on the other, no one ever took more pains to show that these truths must be proclaimed to both rich and poor by an organized body, whose understandings were to be diligently cultivated and exercised, and whose teachings were most profitable when they were not captiously disputed, but humbly received. He may possibly have dreamed, like other great thinkers, of constructing a philosophical system. If he had accomplished such a task, we should probably have found the same reason to complain of it as of any other which has passed under our review in this article. But in the writings which he has left, he has been happily preserved from this infirmity of noble minds. All the principles which he has developed refer to some practical subject, either connected with the regulation of our lives or with the political circumstances of the country. In his books he has thrown out many thoughts with which taken singly we entirely disagree. But we are convinced that he did not mean them to be taken singly. He had confidence that his readers, if they thought it worth while to study any part of his utterances, would study the whole of them, and would gather his meaning not from detached sentences, but from the impression which after a careful and affectionate study remained upon their minds. He felt, perhaps, more strongly than any philosopher since Plato the worth of the principle, that every deep truth comes forth in two imperfect and even apparently contradictory forms; in neither of which singly, but in the result of both, we have that wherein we can permanently rest. We should say, that in the development and application of this truth consisted his great and peculiar

Moral and
Metaphy-
sical Phi-
losophy.

merit as a philosopher. He derived it not from the schools of Germany, but of Greece. But he owed the clear sense of it to his English education. He had received from that our English habit of balance and compromise, which leads in low and feeble minds to the sacrifice of every thing positive and true; but which becomes in our practical Jurists an exquisite tact in deciding the worth of contradictory evidence; which leads our wiser Statesmen to seek after a constitutional equilibrium not in theory but in fact; which disposes our working Divines to be discontented till they can find some point of practical reconciliation between two opposite opinions; which has enabled our Philosophers and Theologians to recognise the Platonic idea as not the more visionary, but the more real, because it cannot reduce itself under the conditions of human logic, and to believe that the deepest principles of Christianity would want one sure test of their derivation from God, if they did not possess the same characteristic.

We have made these remarks, not for the sake of exalting our own countryman, but in order to show that each of the three nations has had its own appropriate task to fulfil, and that its philosophers cannot avail themselves of the labours of foreigners, unless they are content to assist in fulfilling it. If Coleridge understood the Germans better than Bentham, it was because he was a more truly English philosopher, because he possessed that national spirit in which the other was wholly wanting. The Englishman who derives his wisdom from France or Germany, the Frenchman or German who merely sits at the feet of English teachers, will, we are sure, be utterly unable to sympathize with those whom he copies and affects to admire. At the same time it is quite evident that the courses of thought which have been followed in Germany, France, and England, though starting from such different points, cannot be kept separate from each other, and that there is a common characteristic belonging to them all. It would be difficult to say in which country the historical spirit has had most opposition to encounter—whether in Germany, from the subjective tendencies of its philosophy; in France, from the worship of the present age; or in England, from the selfishness by which we have corrupted our institutions, and thus made the doctrine plausible that they were the work of barbarians. It would be difficult to say in which of these countries this spirit has put itself forth most strongly in defiance of all these contradictions, and often in spite of the very habits and tempers of those who have assisted in diffusing it. The mind of Schelling is probably much disposed to look upon truths as derived from the reason rather than as recognised by it. The mind of Guizot must be naturally much inclined to honour the time in which he lives, and to disparage the past. Coleridge's mind was essentially poetic and creative; to him of course the acknowledgment of truths, as given to us not as originated in us, must have been most difficult. Yet each of these men was by different processes led to feel that the highest vocation of the philosopher is to perceive that which is, to discover a meaning in that which has happened, to receive that which has been bestowed. To cultivate this spirit in the students of

Moral and Metaphysical Philosophy should, we conceive, be the great aim of the teachers in these nations. For the most plausible sophisms of our day are upheld by vague notions respecting the history of human progress, and can only be confuted by a patient meditation upon it. We are told in dim prophetic language that certain great metaphysical Ideas have ever clothed themselves in religious forms and notions, which after a while became antiquated, and are exchanged for others; that the period is come when the creed which our fathers have believed must be discarded like the Paganism of former days; that a free and glorious Pantheism will, in the minds of the wise few at least, supersede all the mythical, superstitious, and partial worships which have existed among men. It may be that the phrases of this rhetoric have made an impression upon the European mind which nothing but experience can efface. It may be that we are destined to learn by a discipline perhaps the most tremendous that the nations have ever undergone, what Pantheism is worth, what it can do for mankind, and what huge, shapeless, monstrous superstitions must emerge out of it, before the Light which we have scorned shall burst forth to restore Distinction and Order, and form the Universe anew. But the utterers of this language appeal to History, and by History they should be encountered. Let the records of Greek speculation be calmly studied that it may be seen what they could, and what they could not do; how much truth there was in them; how utterly false they must have been if there be no such divine and transcendent Facts as Christianity consists of. Let it be seen whether Jewish History be really a collection of startling prodigies, or whether it be not the most orderly coherent narration which the world possesses, revealing the deepest principles through events which make those that are happening to us intelligible. Let it be seen from the History of Modern Europe, whether the human spirit does not owe all its emancipation and all its progress to the belief that it is connected by an actual bond with its Creator; whether it did not fall again into bondage and confusion when it lost sight of the Facts by which that Union is declared; whether any attempt to establish Human Society and Human Life upon any other basis than these facts has not ended in the degradation of both. These things if the student diligently ponder in the only temper which can make History or Philosophy profitable, he will find the difference between receiving the truths which any age was appointed to impart, and making that age an object of idolatry; between an affectionate sympathy with those who proclaimed the wants and hopes of man, and the fancy that the announcement of these wants is a substitute for the satisfaction of them; between the belief that the philosopher has faculties given him which he is not to hide, but to use for the good of mankind and the glory of his Creator, and the notion that he can dispense with one of those helps in attaining a knowledge of himself and of God, which are necessary to the meanest peasant. Above all he will see these words inscribed upon the Halls of Philosophy not less legibly than upon the Temple of Religion, "WHOSO HUMBLETH HIMSELF SHALL BE EXALTED, WHOSO EXALTETH HIMSELF SHALL BE ABASED."

Law.

Jurisprudence distinguished from Ethics.

PRELIMINARY OBSERVATIONS.

1. BETWEEN the sciences of Ethics and JURISPRUDENCE, or LAW, there is a connection so close that it is not very easy to determine accurately the respective limits of each. But in a general way, the circumstance which occasions the distinction between them is *compulsion by public authority*. The science of ethics acquaints us with our duty, and the reasons of it. Jurisprudence proceeds to the consideration of the means of enforcing that duty, by the artificial institution of a public and regular system of compulsion, and it inquires into the rules ordained for this purpose. A distinction of another kind is sometimes made. Morality, it is said, relates to principles of action; law, to precise and definite rules of conduct. There is some foundation for this distinction, arising from the peculiar object which each science has in view, though the fundamental principles, and, in a great measure, the practical rules also, are the same in both. In morals, we seek for a just method of self-government; our aim is the private regulation of our own conduct; and we look, not so much to the outward form of our actions, as to the spirit and intention by which we are actuated. Here then we may refer our conduct immediately to the most general standard of right, whereas compulsory enforcement and prevention, which form the proper and immediate objects of law, must necessarily be exerted in single and definite acts, are applicable only to outward conduct, and therefore require precise rules for their application. And, accordingly, we find that Hooker represents law, in its essential character, to be both coercive and precise: "That which doth assign unto each thing the kind, that which doth moderate the force and power, that which doth appoint the form and measure of working, the same we term a law."*

Jurisprudence universal and particular.

2. Jurisprudence is either universal or particular. The former relates to the science of law in general: it investigates the principles which are common to all positive systems of law, apart from the local, partial, and accidental circumstances and peculiarities by which those systems respectively are distinguished from one another. Particular jurisprudence treats of the laws of particular states; which laws are, or at least profess to be, the rules and principles of universal jurisprudence itself, specifically developed and applied.

Conflicting opinions of the limits of jurisprudence.

3. According to some eminent continental writers of the present day, the science of jurisprudence properly admits of being treated in four different ways, philosophically, historically, didactically or dogmatically, and exegetically. The philosophy of law embraces those moral considerations and reasons upon which all laws are grounded: it investigates the origin and principles of natural justice or right, and the sources and object or purpose of positive laws. The history of law traces its actual rise and progress. The didactic branch is concerned with the formal rules and doctrines of law, without directly regarding its spirit and object. And lastly,

* *Ecclesiastical Polity*, book i. sec. 2.

it is the office of the exegetic department to interpret and explain these rules and doctrines.* Universal or general jurisprudence is sometimes called the science of *legislation*. Legislation indeed is occasionally considered as the *art* of the law-maker, whilst jurisprudence is treated as the science. An able living writer, however, of our own country, whose work upon the present subject has attracted a considerable share of notice both here and on the continent, contends that jurisprudence and legislation are entirely distinct sciences. "General jurisprudence, or the philosophy of positive law," says Mr. Austin, "is not concerned directly with the science of legislation. It is concerned directly with principles and distinctions which are common to various systems of particular and positive law; and which each of those various systems inevitably involves, let it be worthy of praise or blame, or let it accord or not with an assumed measure or test. Or (changing the phrase) general jurisprudence, or the philosophy of positive law, is concerned with law as it necessarily *is*, rather than with law as it *ought* to be; with law as it must be, *be it good or bad*, rather than with law as it must be, if it be good."† The learned author, it will be readily seen, dissents from the writers above referred to, and we believe from most others also, in his use and application of the term *philosophy of law*. Legislation, he says, is a branch of morals, and as such distinct from the science of jurisprudence. It is not very clear what limits he would assign to the latter, but apparently he would make it little more than a science of terminology. At the same time his book abounds with many accurate and useful definitions and distinctions; but, like Bentham, for whom he professes to entertain a profound admiration, he betrays an excessive anxiety to arrive at a degree of accuracy, probably unattainable in such a science as law. Attempts of this kind tend rather to perplex than to assist the student. Some of the most instructive works relating to or connected with the science of jurisprudence, are such as it would be difficult to class under any single recognised head or division of the subject; nor, in our opinion, would any great advantage follow, were it possible to satisfy the most restless inquirer upon this point.‡

Law.

* *Introduction Générale à l'Histoire du Droit*; par M. E. Lermier, ch. iii. Warnkœnig, *Doctrina Juris Philosophica*, cap. i. sec. 1.

† *The Province of Jurisprudence determined. Preliminary Observations*, p. iii.

‡ "Of what stamp," asks Mr. Bentham, "are the works of Grotius, Puffendorf, and Burlamaqui? Are they political or ethical, historical or juridical, expository or censorial? Sometimes one thing, sometimes another: they seem hardly to have settled the matter with themselves. A defect this to which all books must almost inevitably be liable which take for their subject the pretended *law of nature*; an obscure phantom, which, in the imagination of those who go in chase of it, points sometimes to *manners*, sometimes to *laws*; sometimes to what law *is*, sometimes to what it *ought* to be. Montesquieu sets out upon the censorial plan: but long before the conclusion, as if he had forgot his first design, he throws off the censor, and puts on the antiquarian. The Marquis Beccaria's book, the first of any account that is uniformly censorial, concludes as it sets out with penal jurisprudence." *Morals and Legislation*, ch. xvii. vol. ii. p. 264, n. He elsewhere

Law.
Lord
Bacon.

4. Lord Bacon has afforded us one of the clearest and most satisfactory descriptions with which we are acquainted of the science now under consideration, whether we designate it by the name of legislation, or of universal jurisprudence; and he enumerates several of the principal problems of which it is the object of that science to offer a solution. "All those," he observes, "which have written of laws, have written either as philosophers or as lawyers, and not as statesmen. As for the philosophers, they make imaginary laws for imaginary commonwealths; and their discourses are as the stars, which give little light, because they are so high. For the lawyers, they write according to the states where they live, what is received law, not what ought to be law: for the wisdom of a law-maker is one, and of a lawyer is another. For there are in nature certain fountains of justice, whence all civil laws are derived but as streams; and like as waters do take tinctures and tastes from the soils through which they run, so do civil laws vary according to the regions and governments where they are planted, though they proceed from the same fountains. Again, the wisdom of a law-maker consisteth not only in a platform of justice, but in the application thereof; taking into consideration by what means laws may be made certain, and what are the causes of the doubtfulness and uncertainty of law; by what means laws may be made apt and easy to be executed, and what are the impediments and remedies in the execution of laws; what influence laws touching private right of meum and tuum have into the public state, and how they may be made apt and agreeable; how laws are to be penned and delivered, whether in texts or in acts, brief or large, with preambles or without; how they are to be pruned and reformed from time to time, and what is the best means to keep them from being too vast in volumes, or too full of multiplicity and crossness; how they are to be expounded, when upon causes emergent and judicially discussed, and when upon responses and conferences touching general points and questions; how they are to be pressed, rigorously or tenderly; how they are to be mitigated by equity and good conscience, and whether discretion and strict law are to be mingled in the same courts, or kept apart in several courts; again, how the practice, profession, and erudition of law is to be censured and governed; and many other points touching the administration, and, as I may term it, animation of laws."*

His
maxims.

5. He attempted to supply in part the deficiency here complained of, by his short but highly valuable treatise entitled *Exemplum tractatus de justitia universali sive de fontibus juris*, appended to the eighth book of his great work *De augmentis scientiarum*. This treatise consists of ninety-seven aphorisms upon the heads enumerated by him as above. The consummate ability, learning, and skill of its author, added to his extensive experience as a practical statesman and lawyer, eminently qualified him for advancing the science of legislation; and these aphorisms are deservedly held in high estimation. By many their appearance is regarded as an important epoch in the history of legal science. Some even

expresses himself dissatisfied with Blackstone, on similar grounds. See Bentham, *Fragment on Government*, Pref. p. xii. &c.

Some sensible remarks, bearing upon the present discussion, may be found in Lieber's *Political Ethics*, part i. ch. iv. sec. 31, p. 67. London, 1839.

* *Advancement of Learning*, book ii.

go the length of asserting that Lord Bacon was the first, in modern times, who conceived the idea of an universal jurisprudence; that it was he who first sowed the seed which has only of late sprung up and produced fruit, in the shape of a more exact theory of law, and improved methods and principles of legislation, though as yet the science is far from being complete. It must indeed be admitted with Mr. Hallam, that the maxims in question are an admirable illustration of the principles which should regulate the enactment and expression of laws, as well as of much that should guide, in a general manner, the decisions of courts of justice, and that they furnish principles of general application, inasmuch as they are not limited to the circumstances of particular societies.* But others again bestow less unqualified praise on the services of our great philosopher, in relation to the advancement of the science at large. Thus M. Lermnier remarks the cautious timidity of Bacon with regard to political philosophy. "Concerning government," says Bacon, "it is a part of knowledge secret and retired, in both these respects, in which things are deemed secret, for some things are secret because they are hard to know, and some because they are not fit to utter;" and, accordingly, the only part which he handles of this branch of the subject, regards the means of extending the bounds of an empire. As to the science of law, considered apart from what belongs more properly to politics, M. Lermnier thinks it may fairly be questioned, whether Lord Bacon has, in reality, given us a treatise on universal justice; for he does not attempt to examine the rational foundation of society, or the basis and groundwork of law. He contemplates laws merely in the outward form they present, and the only principles with which he furnishes us relate exclusively to their practical regulation and administration. So far he is admirable, it is conceded; but with respect to the theory and philosophy of law, his maxims cannot, as this ingenious writer contends, be allowed any rank or importance in the history of the science.†

6. For the philosophy of law we may go back to the ages of antiquity, to those philosophers of whom Lord Bacon says, *proponunt multa, dictu pulchra, sed ab usu remota*; who have explored the fountains of justice without pursuing its streams. We do not now refer to works exclusively or principally of a moral as opposed to a political cast, however such works may assist the jurist, by the light which they afford him in his search after the common foundation of morals and law. At present, we are concerned only with such writers as have directly contributed to promote the science of jurisprudence. Plato is generally ranked amongst the earliest and most remarkable of these writers. His views are comprehensive, noble, and just; though perhaps his diffuse and unsystematic style, and the form of the dialogue in which he has chosen to clothe his ideas, may be looked upon as defects by the rigid lovers of system. Two of his dialogues, the *Commonwealth* and the *Laws*, are very commonly, though erroneously, supposed to be connected with one another, as if in the latter he intended to follow up and complete the plan which he

Law.

The phi-
losophers

Plato.

* See Hallam's *Introduction to the Literature of Europe in the XIVth, XVth, and XVIth Centuries*, vol. ii. p. 444, &c. See also the remarks of Mr. Basil Montagu, the learned editor of Lord Bacon's Works, vol. ii. p. lxvii., and note U.

† Lermnier, *Introd. Gén. à l'Hist. du Droit*, ch. vii.

Law. commenced in the former, by furnishing his imaginary community with imaginary laws. The two works in question, however, are wholly unconnected. Plato had no intention of representing any actual or probable condition of society, in his *Commonwealth*, a work which has reference to morals, rather than to our present subject. The supposition, therefore, occasionally entertained, that he seriously countenanced doctrines much resembling those which are attributed to the Saint-Simonians and certain other modern sects on the subjects of property and marriage, is equally absurd and groundless. In his *Laws*, he appears more properly in the character of a politician and a statesman; and if we consider the age in which he lived, and the lights which he possessed, he stands unrivalled as a *political philosopher*. We are to look to him chiefly for general views, respecting the true object of government, the duties of a legislator, and the fundamental principles of legislation; at the same time he is highly valuable on several matters of detail and of a practical bearing. In some respects, he seems to have anticipated the doctrines of modern theorists, as, for example, where he treats of the nature, object, and proportion of legal punishments, and the circumstances which he thinks ought to accompany the promulgation of laws. The concluding books of this work contain a system of municipal and international law.

Aristotle. The depth and precision of Aristotle, the anatomy of justice, which he gives in his *Nicomachean Ethics*, and the unrivalled sagacity, diligence, and exactness, with which he has traced and explained the structure of human governments, place him, even now, in the very first rank of political writers; but he far surpasses them in general, in one most important respect, namely, in the regard he pays to experience, and in his close observation of human nature. His theory of justice is encumbered with a whimsical attempt to establish a sort of moral arithmetic, justice being made to depend upon a geometrical proportion; but when he extricates himself from this, his good sense is apparent. His political doctrines are to be found in his *Politics*. The first book contains the theory of slavery and sociability. His doctrines with regard to the former are amongst those which have been most frequently and severely censured: whole races of human beings, he asserts, are decreed by nature to be slaves; and on this unsatisfactory principle he justifies the practice of reducing our fellow creatures to the mere condition of *things*. In the second book, he criticises the theories of Plato and of other philosophers, and reviews the constitutions of Sparta, Crete, and Carthage. In several succeeding books, he establishes the principles on which civil society is instituted, and traces the nature and forms of the various sorts of government, simple and compound, the course of revolutions, and the causes of the decline of states. That he did not theorize without regard to facts and experience, appears from the circumstance, that, as a preparatory step, he examined and compared one hundred and fifty-eight different constitutions of Greece and Italy. Afterwards, he proceeds to investigate the conditions of private justice and of social happiness, and many points of practical legislation and government. The eighth and last book is occupied with the subject of education.

Cicero.

7. The next philosopher to be noticed is Cicero. But he is distinguished, not so much for having advanced the principles of the science, by any original discoveries of his own, as for the conspicuous place which

he occupies in Roman jurisprudence, which first began, in his day, to be enriched and improved by its alliance with Grecian philosophy then recently imported into Rome. Before the time of Cicero, law was merely practised there as an art. He entertained the idea of reducing it to a regular science,* a task which was partly executed by his friend and contemporary, Servius Sulpicius. Cicero was not a professed jurisconsult, but he was intimately acquainted with the Roman laws and constitution, and to him we are indebted for some of the most valuable information we possess respecting them. He may justly be regarded as pre-eminently the philosophical jurist of Rome. Two treatises of his, on political and legal philosophy, have been transmitted to us, but in a very mutilated condition, about one half of each being lost. One of these, his treatise *De Legibus*, has long been known. Of the other, bearing the title *De Republica*, we possessed only a few fragments, chiefly quoted by Lactantius, until, in the present century, the work, as we now have it, was brought to light by the learned Cardinal Mai. In the titles of these works, in his adoption of the form of a dialogue, and in his general philosophy, Cicero has imitated Plato. His political science, relative to the structure of governments, is chiefly borrowed from Aristotle. In his *Commonwealth*, he discusses the excellences and defects of the different forms of government. In remarking upon the excellence of the Roman constitution, he attributes its superiority over those of the states of Greece to the fact, that whilst they were originally framed or largely reformed by the single efforts of distinguished individuals, the Roman constitution was slowly and gradually developed in the course of many ages, and by the successive labours of many statesmen.† Such, he maintains, must always be the process, by which a constitution is brought to maturity and rendered really and substantially good. Hence he proposes, as the most proper and rational method of prosecuting his inquiry into the best form of government, to trace the rise and progress of the Roman constitution from its earliest infancy; a method, in his opinion, far preferable to that adopted by Plato, who feigned an imaginary commonwealth. He then proceeds, with consummate ability, to review the principal epochs and changes in the constitution of his country; but, unfortunately, we are prevented from following him to the end, by the loss of the latter portion of this work. In his *Laws*, Cicero eloquently maintains the divine origin and immutable character of natural justice or right, independent of all human conventions and opinions. He shows the connection between law and religion, and strenuously asserts the obligation of states to support a national faith and established religious institutions. He then passes on to the appointment and

* "Si enim aut mihi facere licuerit, quod jamdiu cogito, aut alius quispiam, aut, me impedito, occuparit, aut mortuo effecerit, ut primum omne jus civile in genera digerat, quæ perpauca sunt; deinde eorum generum quasi quædam membra dispertiat; tum propriam cujusque vim definitione declaret; perfectam artem juris civilis habeatis, magis magnam, atque uberem, quam difficilem atque obscuram." *De Oratore*, i. 42.

† "Is (scilicet Cato) dicere solebat, ob hanc causam præstare nostræ civitatis statum cæteris civitatibus, quod in illis singulis fuissent fere, qui suam quisque rempublicam constituissent legibus atque institutis suis, ut Cretum Minos, Lacedæmoniorum Lycurgus, Atheniensium, quæ persæpe commutata esset, tum Theseus, tum Draco, tum Solon, tum Clisthenes, tum multi alii; postremo exsanguem jam jacentem doctus vir Phalereus sustentasset Demetrius. Nostra autem respublica non unius esset ingenio, sed multorum, nec unius hominis viâ, sed aliquot esset constituta sæculis et ætatibus." *De Rep.* lib. ii. 1.

Law.

functions of magistrates, the constitution of senates and popular assemblies, and the other topics of constitutional law and policy. The imaginary republic, represented in this work, bears a close resemblance to the Roman state, for which it has frequently been mistaken.

8. Of the ancients, those whom we have noticed are commonly regarded as the chief promoters of philosophical jurisprudence. After them, we do not, until we come to modern times, meet with the names of any writers in this particular department, of sufficient importance to render their appearance an epoch in the history of the science. We shall now proceed to mark out the principal eras, and notice a few of the chief events connected with the gradual development and progress of practical jurisprudence.

The Roman law.

9. The science of positive or artificial law in general may be considered to have but recently emerged from a state of infancy, in the time of Cicero, when, as we have already intimated, the Roman law first attained the rank and dignity of a science. "From that time," to use the language of Lord Bacon,* "there was such a race of wit and authority, between the commentaries and decisions of the lawyers, and the edicts of the emperors, as both law and lawyers were out of breath." Without pausing to enumerate the particular circumstances which led to such a result, it is sufficient at present to notice the fact, that the Roman law gradually lost much of the narrow character of a purely national system, intended for the regulation of a single people, and accommodated itself to the widely differing manners, customs, and ideas, of the various nations composing the empire. The progress of the system towards maturity, and its ultimate establishment on a broad philosophical basis, was materially promoted by the labours of a series of profound and accomplished lawyers, who followed each other in uninterrupted succession down to the age of Alexander Severus; in and about whose reign the illustrious names of Papinian, Paul, Ulpian, and Modestinus occur. So far as principles were concerned, the Roman law had now attained its full maturity; for the lawyers of the next three centuries possessed no originality, but contented themselves with a tame use of the rich materials left to them by their predecessors, without attempting to develop any new principles. Their highest ambition did not rise above several attempts,—some of them tolerably successful,—to reduce and abridge into a more convenient size and form, the contents of the unwieldy mass of their law books. Gregory and Hermogenes, two private lawyers of the age of Constantine, collected and arranged, in the Gregorian and Hermogenian Codes, the imperial edicts down to their times. Nearly a century after, a similar collection, in continuation of the others, was made by order of the Emperor Theodosius the younger. This collection was called the Theodosian Code, and it was the first work of the kind undertaken by public authority. But the most remarkable achievement in this way, indeed we may perhaps say, the most remarkable event in the annals of jurisprudence, was the remoulding of the whole body of Roman law, in the early part of the VIth Century of our era, by command of the Emperor Justinian. Tribonian, an eminent lawyer of the day, was the chief instrument employed in this task. The body of law, as digested and arranged by him assisted by other lawyers, comprehended origin-

The classical juris-consults.

Codes.

The civil law.

ally three distinct works: 1. the Code in twelve books, consisting of the imperial constitutions methodically arranged, from the earliest times of their promulgation; 2. the Digest or Pandects, in fifty books, containing the opinions and writings of the most eminent lawyers, digested in a systematical manner; 3. the Institutes, being an elementary treatise on the Roman law, in four books. To these were afterwards added the Novels, or imperial constitutions of posterior date, which formed a supplement to the Code; for, notwithstanding Justinian's determination that the first three works should form the only standard of reference in all civil matters, for his own and all future times, it was found impossible to dispense with subsequent legislation. These four compilations together compose what is technically called the *Civil Law*, in contradistinction to the Roman law, which is a more general term, and includes the ante-Justinianean jurisprudence as well, though frequently the two names are used indifferently to denote the same thing. With the compilation of the *Corpus Juris Civilis*, the history of the Roman law, properly speaking, ends.

10. During the dark ages, which succeeded the final The dark overthrow of the Roman empire, legal and all other ages. science was overwhelmed in confusion and ignorance.

The descendants of the ancient Romans, however, were still permitted, by their barbarian conquerors, the use of their own laws; and, though jurisprudence was no longer cultivated as a liberal science, the books of the civil law, as Savigny has clearly proved,* were in the hands of the lawyers of those days, and, however imperfectly understood, formed one source from which a knowledge of Roman law was derived. For a long time,—indeed the general impression so long cherished is yet far from being entirely removed,—the favourite theory, so successfully overturned by Savigny, was, that the Theodosian Code and other inferior compilations were the only known repositories of Roman law, until accident led to the discovery of a copy of the Pandects at Amalfi, in the beginning of the XIIth Century. While the civil law,—so far as its liberal cultivation, as an object of science, was concerned,—was thus in abeyance, two other great systems were partially brought to light. These were the Feudal and the Canon laws. The former The feudal law. was that system of polity which was introduced by the northern nations who overran the Roman empire, and whose customs were, for the most part, nearly similar. It is generally supposed to have acquired something like a systematic form about the time of Charlemagne, who was desirous of effecting, as far as possible, an uniformity of law throughout his extensive dominions; but the principal collections of this law were not compiled until after the dark period we are now considering. The account which is given in our HISTORICAL DIVISION of the Rise, Progress, and principal Features of the Feudal system, will supersede the necessity of saying much upon it in the present article. The Canon law was the rule of the Christian church, and, properly speaking, it The canon law. was coeval with the general adoption of Christianity in Europe. But before the Papal dominion attained its full height in the latter part of the XIth Century, this system was described simply as a *rule*; it then was dignified with the name of a *law*; and thenceforward it

Law. obtained great influence in most countries of Europe. Several collections of canons were made in the dark ages, but the chief collections, forming what is called the *Corpus Juris Canonici*, were not compiled till a later period.

Jurisprudence of the middle ages. 11. The subsequent history of jurisprudence is separable into two grand periods, that of the middle ages, and that of modern times. The former begins about the year 1100, and occupies a space of about four centuries; and it is remarkable principally for the zealous cultivation of the civil law in Italy, and, in a subordinate degree, for the ulterior developement of the feudal and canon laws. The Italian civilians of the middle ages are commonly divided into three schools, those of Irnerius, Accursius, and Bartolus. Irnerius was a native of Bologna, where he professed and taught the civil law, with such remarkable success, that it soon became the favourite study, and continued to hold the chief place among the sciences throughout the whole period now under consideration. Students from every quarter of Europe flocked to the Italian universities, for the purpose of gaining an intimate acquaintance with this law; and such was the estimation in which it was held, that in a short time it was adopted by almost all the European nations as the basis of their legislation.

The Italian civilians. Irnerius. The Glossators. Irnerius was the founder of what is called the school of the glossators, from the glosses or marginal notes which the professors of the civil law were in the habit of writing upon the text. After some time, these glosses usurped, in a great measure, the place and authority of the text, and at length they multiplied to such an extent, that a general digest of them was thought desirable. The project of composing such a digest was conceived and executed by Accursius, who compiled his *Glossa Ordinaria* about the middle of the XIIIth Century. This compilation had immense and rapid success, for it soon obtained the force of law in the public tribunals, and it put the old glosses so completely out of fashion, that they were soon forgotten, and in many instances destroyed as useless lumber. Savigny speaks very slightly of it, and he says that its indifferent execution, and the extraordinary favour it met with, attest the decline of the science since the times of the earlier Irnerians.

Accursius. Bartolus. Bartolus, the chief of the third school, flourished about a century later than Accursius. He was chiefly celebrated as a commentator, and it was for his great superiority over his predecessors in this department, more than for any thing original in the character of his writings, that he was regarded as the head of a school. Zeal and industry constituted a large portion of the merits of the Italian civilians, for they had neither philosophy, history, nor polite learning, to aid them. Of all the collateral departments of knowledge, logic alone, at a somewhat advanced stage of this period, was blended with jurisprudence, but that in a way rather to encumber than to assist the latter science.

The feudal and canon laws. 12. Whilst the feudal law regulated the tenure of property, and the canon law the ecclesiastical relations of the states of Europe, each of those systems, in a scientific point of view, occupied, during the middle ages, a very inferior position to the civil law, which was regarded as the great repository of legal science, embodying all the essential principles of universal jurisprudence; and it continued to be viewed in this light till after the Reformation. The feudal and the canon laws borrowed largely from it. Codes and digests of feudal and canonical learning were from time to time compiled

on the model of the books of the *Corpus Juris Civilis*. Like the latter too, these compilations became the subject of numerous glosses and commentaries. Bulgarus an eminent civilian of the XIIth Century, supposed to have been a pupil of Irnerius, is said to have been the first who wrote a gloss on the Book of Feuds, the principal collection of feudal law. His example was followed by many others, who were, for the most part, civilians likewise. With regard to the canon law, when it obtained the influence we have above alluded to under Pope Gregory VII., in the XIth Century, a knowledge of it became a common road to the highest honours, and hence it had many followers. For some time the glossators and the canonists formed two entirely distinct classes; occasionally too, some degree of rivalry and jealousy was observable between them. By degrees, however, the canonists regarded the civil law as an integral part of their studies; and, on the other hand, the civilians, in their works, made use of many principles derived from the canon law. The first instance of the same individual professing both laws at once, occurs about the beginning of the XIIIth Century, in the person of Lanfrancus, a professor at Bologna. Afterwards the practice became not uncommon.

13. The modern period begins in the XVIth Century, about the time of the Reformation, when the science of jurisprudence underwent a complete revolution. Towards the close of the preceding period, the defects of the existing modes of studying and cultivating the civil law began to be pretty generally felt and acknowledged, and some eminent scholars, such as Politian, brought history and polite learning to bear upon the civil law. These latter, however, studied and wrote upon the books of the civil and Roman law, as philologists, not as lawyers, and until the following century, no material improvement took place amongst the regular professors, who still persisted in the old barbarous and vicious system. France, Holland, and Germany, may be singled out as the three countries where the civil law has been most successfully cultivated in modern times, though other countries as well have produced many eminent civilians. The founder of the *Erudita Jurisprudentia* was Alciatus, an Italian by birth, who settled in France, originally at Avignon, from whence he was removed in 1529 by Francis I., who was ambitious of promoting the study of the civil law in his dominions, and, with that view, placed Alciatus as professor of it at Bourges. The attempt of Francis completely succeeded, for the French became the most illustrious of all the modern schools. Of the many most learned and accomplished lawyers whom it produced, we need only mention the names of Duaren, Govea, (by birth a Portuguese,) L'Hospital, Hotman, Cujacius, Donellus, Brisson, James Godefroi, Domat, D'Aguesseau, and Pothier. Of all these, the reputation of Cujacius, or Cujas, stood so high, eclipsing that of the founder Alciatus, that the French is commonly called the Cujacian school. He is supposed to have been the profoundest civilian who has appeared since the days of Justinian. His works are very numerous. Most of them are of an expository character; hence he was regarded as the head of the exegetic, whilst his contemporary and rival Donellus, who wrote treatises, was considered as the chief of the didactic school of their day. Cujas died in the year 1590.

14. France took decidedly the lead for nearly two Dutch centuries, until it found a rival in Holland. The Dutch school.

Law.

school may be considered to have commenced with the founding of the university of Leyden in 1575, to which place Donellus was invited about that time, he being obliged to leave France on account of having embraced the reformed religion. It was he who gave the first great impulse to the study of the civil law in Holland. Other universities were subsequently founded, each of which had its law professors. Grotius and Vinnius flourished about the middle of the XVIIth Century; Van Leeuwen and Huber towards its close. In the following century we have the names of Voet, Westenberg, Schulting, Noodt, and Bynkershoek. These raised the reputation of the Dutch schools so high, that students in general repaired to Leyden and Utrecht, instead of to Bourges and Toulouse. In the political changes and revolutions which afterwards took place, the universities and law schools of Holland suffered; and though these afterwards partially recovered, Holland has not regained its former position. It has now a respectable school of law, but it cannot pretend to vie with the schools of Germany.*

German school.

15. Zasius was the founder of the German school. For a long time the voluminous works of the civilians of that country were extremely heavy and barbarous in their style, though exhibiting much industry and research. Haloander, who died in 1531, is one of the first names really deserving of notice. He was distinguished chiefly for his learned edition of the *Corpus Juris Civilis*, in which the Greek Novels, hitherto known through a Latin translation, were for the first time given in the original. During the latter part of the same century many professors of distinguished merit appeared; most of them, however, were foreigners, as Giphanius "the boast of Germany," Donellus,—already noticed as adorning the jurisprudence of France and Holland,—Balduinus, and Gothofredus the elder, whose edition of the *Corpus Juris Civilis* makes an epoch in jurisprudence, being the text-book generally received. In the XVIIth Century, this school degenerated; but towards the close of the same century, the historical study of the Roman law began to make some progress. The most conspicuous German civilian of the XVIIIth Century was Heineccius, whom Sir James Mackintosh designates as the best writer of elementary books with whom he was acquainted on any subject.† At present Germany is unrivalled in this branch of learning. A new school of historical jurisprudence, founded several years ago by professor Hugo, who is now living at an advanced age, has firmly established itself there, and is gradually extending its branches to other countries. A conspicuous ornament of the same school, Haubold, died a few years ago. The works of these two authors are extremely valuable. But its acknowledged chief is professor Savigny of Berlin, the learned historian of the Roman Law in the Middle Ages. The field of historical jurisprudence is comparatively new, for none of the French Cujacian school undertook a work strictly historical, unless Gruchy and a few others can be considered as exceptions; and although something was formerly done in Germany and Italy, much yet remains to be explored.‡

† *Discourse on the Study of the Law of Nature and Nations*, p. 27.

‡ Irving's *Introduction to the Study of the Civil Law*, p. 165, &c.

16. The civil law has been cultivated with more or less of success in other countries. Spain and Portugal have produced some eminent civilians. So has Italy; though, as compared with other countries, it has never in modern times resumed the rank it formerly held. Gravina, however, a native of Calabria, and professor of civil law at Rome, somewhat more than a century ago, deserves to be singled out as the most elegant and classical of modern civilians. His *Origines Juris Civilis*, is a work of learning, and of great taste and judgment. In England the civil law has been much neglected, though it has contributed very largely,—much more largely than is commonly imagined,—to our national jurisprudence. Dr. Duck, the author of an elaborate and very useful treatise on the Use and Authority of the Roman Law in the Dominions of Christian Princes, is one of the few English civilians who enjoy any share of continental reputation. He lived in the earlier part of the XVIIth Century. For a fuller account of the principal civilians and their works, our readers may consult with advantage Dr. Irving's useful publication on the *Study of the Civil Law*, to which we are indebted to some extent in the preceding observations. Although the civil law has ceased to be regarded with the same unqualified deference which was paid to it in former times, although, too, modern changes have in several instances superseded its direct authority, and given it but a secondary place in countries where it formerly held the first, it still forms a most important object of study for all who would wish to become acquainted with the origin of a very large portion of the jurisprudence of the modern world. A strong testimony is borne to its philosophical excellence, by several modern theorists, who often silently borrow many of their principles and distinctions from it, whilst they affect to be wholly independent of any positive system.

17. Under the effects of increasing civilization, the rigour of the Feudal law was gradually modified and softened, and many of its incidents were at length superseded. Yet it has left so many and deep traces behind it, that a knowledge of it is not only interesting, but indispensable, in order to understand the principles which govern the modern laws of property. Feudal learning received a considerable share of attention in France from the contemporaries and successors of Cujacius, as well as from several writers of other countries, according to the various national forms in which that law was modified. In Germany, this, like every other branch of jurisprudence, has been assiduously cultivated. In England, we had our own Littleton, before the commencement of the modern period; and afterwards, Spelman, Wright, Gilbert, and many others. In Scotland, the feudal law, as there applied, has been illustrated with much learning and ability by Sir Thomas Craig, one of the greatest lawyers whom his country has produced.*

18. With regard to the Canon law, the different authoritative collections contained in the *Corpus Juris Canonici*, were completed before the commencement of the modern period. Though the authority of the Canon law was much impaired by the Reformation, it still forms the basis of the ecclesiastical law of every country where the Roman Catholic religion is professed, and even in Pro-

Law.

Cultivation of the civil law in other countries.

Law.

testant countries, generally speaking, it has the force of law, where it is not repugnant to the law of the land.* The most distinguished canonist of the last century was Van Espen of Louvain. Spain has generally been distinguished for its canonists. In Germany, the Canon law has received much attention, even at the Protestant universities; we are told that when Boehmer was dean of the University of Halle, early in the last century, he acquired so great a reputation in Italy as a canonist, that difficult and complicated processes were frequently sent for the decision of the law faculty in that Protestant university. At the present day, the Canon law is by no means neglected in Germany. Though, in point of importance, it cannot be placed upon an equal footing with the feudal and civil laws, it is nevertheless a study of occasional importance even to lawyers.

19. Without going too much into detail, or anticipating what remains to be said in the body of this essay, the preceding observations may suffice to convey some general notion of the advance and progress of the three great systems which together constitute the triple basis of the national jurisprudence of Europe. Modern times have been tolerably fruitful in theories and speculations on the abstract principles of law; they have also developed another great positive system, regulating the intercourse of civilized states, and called the Law of Nations.

Modern
speculative
writers.

20. The spirit of free inquiry which accompanied the revival of learning and the Reformation, extended itself to politics and jurisprudence. Machiavel first reduced statecraft to system; but his works, though nearly related, scarcely belong to our present subject. Several theoretical writers on law and politics appeared in the latter half of the XVIth Century, of whom Bodin, an eminent French lawyer, held by far the most distinguished place. "No former writer on political philosophy," observes Mr. Hallam, "had been either so comprehensive in his scheme, or so copious in his knowledge; none perhaps more original, more independent and fearless in his inquiries. Two names alone—Aristotle and Machiavel—could be compared with his."† The work of Bodin which elicited this eulogium, is his *Republic*, written in Latin; a work which has often been compared with Montesquieu's *Spirit of Laws*, and which in many respects bears a close resemblance to it; and a comparison of the two together will go far to lessen Montesquieu's claims to originality, in some important respects. The *Republic* excited extraordinary interest in its author's own day, and it became and continued to be the text-book of political students until the time of Grotius. An erroneous idea has gained ground with some persons, that it was made the subject of public lectures at Cambridge in the lifetime of its author, an error probably arising from the favour the book met with, as an object of private study, at that university. At present, it is not much read or known. The first book commences with an inquiry into the end or object of political society. Man is considered successively in his private and in his public relations, as a member of a family, and a member of the state. Under the former relation, the subjects of marital and paternal authority, and domestic servitude, are discussed; under the latter, the origin of commonwealths, (which Bodin founds in an original compact,) the general rights and privileges of

Bodin.

citizens, and the nature of sovereign power. The second book is occupied with an examination of the different forms of government. The third book treats of senates and councils of state, of the powers and duties of subordinate magistrates, of corporations and other public bodies, and of the different orders of citizens,—freemen as well as slaves,—considered in their relation to the state. The topics discussed in the fourth book, which is disfigured by some strange astrological fancies of the author, are the rise and fall of states, and the causes of revolutions, the impolicy and danger of sudden changes, the extent and limits of the judicial authority of the sovereign, and toleration in matters of religion. In the fifth book, he examines at large the influence of climate upon the principles of government. Here he anticipates Montesquieu, this being one of the main topics for which the latter is celebrated, and on which his claim to originality is chiefly founded, however little value the theory itself may be thought to possess. Bodin next proceeds to consider the means of checking luxury, and obviating great inequalities in the possessions of individuals; how property confiscated for crime should be disposed of; and how the state should regulate its rewards and punishments; lastly, he considers the subjects of war, domestic and foreign, alliances, and the rights of ambassadors. The first part of the sixth book relates to the public census of property, public revenues, taxation, and coining. The author then proceeds to a comparison of several forms of government, in which he gives the preference to the monarchical form; and he concludes his treatise with a theory of justice.

21. Bacon, the next great name that follows in chronological order, directed his attention chiefly to the machinery of law; but it is unnecessary to add any thing further to our previous observations respecting this great philosopher. Selden, who succeeded him, and was one of the most learned men whom England has produced, enriched the literature and jurisprudence of his country by his researches into legal and constitutional antiquities. In his celebrated treatise entitled *Mare Clausum*, he claimed for England the exclusive dominion of the seas, in opposition to Grotius, who espoused the cause of his countrymen, the Dutch, in their claim to the right of fishing upon the British coast. The general principles involved in this controversy invest it with an interest beyond the mere matter in dispute. Selden is also considered to have made some advances towards a development of the law of nature, in his treatise *De jure naturali et gentium juxta disciplinam Hebræorum*; in which he separates what he considers to be of universal and essential obligation, from the more positive and purely national parts of the Jewish law.

22. But the man who has done the most, in modern times, for the science of jurisprudence, is Grotius. Dr. Adam Smith considers him to have been the first who attempted to give the world any thing like a system of those principles which ought to run through and be the foundation of the laws of all nations.* It is true, that before Grotius wrote, Bacon started the idea of an universal jurisprudence; yet, after all, the latter did little more than suggest the existence of such a science, and offer a few though valuable axioms, of general application. Grotius investigated the subject in all its bearings. He placed the science on a sure and sound footing, and may justly be regarded as the parent of what has since

Law.

Law.
The law of
nations.

been called the Law of Nature and Nations. The same remarks will apply to him considered as the author of the positive Law of Nations, meaning thereby, that system of artificial rules and customs by which the intercourse of civilized independent nations is governed; for the labours of Albericus Gentilis, and other authors of inferior note, who preceded Grotius in this department, were not so successful as to entitle any of them to be accounted the parent of International Law. The two sciences, here spoken of as distinct, were blended and treated of together in the celebrated work of Grotius *De jure Belli et Pacis*; and they have since been frequently regarded as parts of the same science. In more recent times, a clearer and more marked distinction has been drawn between them; and it is now pretty generally admitted that there is no more necessary or intimate connection between the Law of Nature and the Law of Nations, properly so called, than there is between the former and the municipal law of any well regulated state. The Law of Nature contains in itself the seeds of all positive laws, national as well as international. It is true, indeed, that in discussing and deducing the rules of the Law of Nations, we are necessarily compelled, from the absence of any common and paramount authority over nations in general, to resort more frequently to reasons derived from principles of universal right; yet, in examining the municipal laws of any particular state, in discussing what the laws of such a state *ought to be*, a similar reference to universal justice is no less strictly necessary. Such was the opinion of Grotius himself, when he pronounced the Laws of Nature to be the *proavia juris civilis*. The phrase, Law of Nature and Nations, is open to some criticism. When it is intended to embrace international law, we should understand the phrase, *of nations*, in the same sense in which the Roman classical jurists understood their *jus gentium*, corresponding more nearly to our *law of nature* than to our modern international law. Perhaps it would have been desirable that this confusion had been avoided. The phrase here criticised seems, however, in a great measure, to be going out of fashion in the present day. As we shall have occasion hereafter to notice the work of Grotius, we shall at present abstain from offering any further remarks upon it.

Puffendorf. 23. Grotius was followed, at an interval of half a century, by Puffendorf, who, in his *Law of Nature and Nations*, further developed and methodized the system of his illustrious predecessor. In the year 1661, he was nominated by the Elector Palatine professor of the law which forms the title of his work, at Heidelberg; and this is the earliest instance of the foundation of such a professorship in any university. Similar professorships were afterwards instituted elsewhere, at Coimbra, for example. Puffendorf separates the law of nature from the law of nations properly so called, and though far inferior to Grotius in genius and learning, he effected an improvement by introducing a better order into the system.

Vattel. 24. A century later, Vattel's *Law of Nations* appeared, which, though it by no means supersedes the works of Grotius and Puffendorf, is more generally used as a text-book; and, as such, it is, in many respects, superior to them. In general, the author adopts the principles of the Saxon philosopher Wolff, and he is therefore regarded as belonging to a different school from Grotius and Puffendorf. Other writers of name have illustrated this science, but it is unnecessary to

swell these observations, by enlarging at present on this branch of the subject. We must, however, mention Law. Burlamaqui, a contemporary, though not the country-
man, of Vattel, and an author of sound principles and superior merit. His treatise on Natural Law is a favourite text-book on the general principles of morality and politics; but the law of nations is not indebted to him to any material extent.

25. In modern political philosophy, amongst a crowd Locke. of inferior names, we may select that of Locke, than whom few have acquired a higher celebrity, or exercised a greater influence on speculative opinions. His *Essay on Government* tended so powerfully to bring the doctrine of the Social Compact into fashion, that although that doctrine was by no means new, it is frequently ascribed to him.

26. Half a century later, we have Montesquieu, who Montes- belongs to a different class, but attained a still higher quieu. celebrity than Locke. His *Spirit of Laws* was published in the year 1748, and it placed its author nearly if not quite at the head of modern legal philosophers. At one time, few books were more read and studied, and though it has now lost much of the great popularity it once enjoyed, it still bears a high reputation. "What former age,"—says Sir James Mackintosh, with reference to the superior advantage in historical knowledge enjoyed by writers of the last over the preceding century,—“could have supplied facts for such a work as that of Montesquieu? He has been, perhaps justly, charged with abusing this advantage, by the undistinguishing adoption of the narratives of travellers of very different degrees of accuracy and veracity. But if we reluctantly confess the justness of this objection; if we are compelled to own that he exaggerates the influence of climate, that he ascribes too much to the foresight and forming skill of legislators, and far too little to time and circumstances, in the growth of political constitutions; that the substantial character and essential difference of governments are often lost and confounded in his technical language and arrangement; that he often bends the free and irregular outline of nature to the imposing but fallacious geometrical regularity of system; that he has chosen a style of affected abruptness, sententiousness, and vivacity, ill suited to the gravity of his subject: after all these concessions, (for his fame is large enough to spare many concessions,) the *Spirit of Laws* will still remain not only one of the most solid and durable monuments of the powers of the human mind, but a striking evidence of the inestimable advantages which political philosophy may receive from a wide survey of all the various conditions of human society.”*

27. Towards the end of the last century, two distinguished political writers appeared in Italy, Filangieri. Filangieri and Beccaria. The former of these, a Neapolitan, was a political speculator of a high order; and the work for which he is celebrated, on the science of legislation, (*Scienza della Legislazione*), published between 1780 and 1789, though it does not appear to have led to any remarkable practical result or movement, is yet deserving of notice, for the learning and knowledge it displays, the spirit in which it is written, and, on such a subject, the rare qualities of temper and moderation in its author. Shortly before this work was published, appeared Beccaria's *Essay on Crimes and Punishments*, ap- Beccaria.

* *Discourse on the Law of Nature and Nations*, p. 24.

Law. one of the earliest works in which attention was much called to criminal jurisprudence. More than two centuries before, Sir Thomas More had condemned, as wanton and unjust, the bloody severity of our own criminal code,* which, during a single reign, consigned to death no fewer than 72,000 thieves and rogues, exclusive of all other malefactors.† Beccaria called in question the necessity of inflicting the punishment of death in any case whatever. "This treatise,"—we quote the words of an anonymous writer,—“contains many acute and just general observations, but applies chiefly to the codes of criminal law which at the date of its appearance were in force throughout the states of Italy; and its principal value, in the present day, must be admitted, even by its greatest admirers, to consist not so much in what the author has himself done, as in what he has taught others to do. His well-founded aversion to the cruelty which marked the administration of criminal justice in his own country seems to have driven him to an opposite extreme, and he now and then suffers language to escape him, which cannot fail to bring the whole of his doctrines into suspicion with those who reverence the foundations on which the good order of society has hitherto been supposed to rest. Such as his doctrines were, however, they were approved and followed by some of the most popular and powerful princes then reigning in Europe. The Grand Duke Leopold of Tuscany took the lead in the career of reform, and from the success which that sovereign says had attended his previous mitigation of the penal code of his dominions, he was induced, on the 30th of November, 1786, to issue that celebrated edict from Pisa, by which he proclaimed the total abolition of capital punishment throughout the states of Florence.”‡ Subsequently, Austria, Russia, and France, followed the example thus set, and revised their criminal codes; and although the well-meant endeavours of these and other states have not in all cases been crowned with success; though they have been obliged, in many instances, to retrace their steps; yet, on the whole, an improvement has been effected by the introduction of a milder spirit into modern legislation; and some part, at least, of the merit belongs to Beccaria.

28. For the last three-quarters of a century, dating from the rise of Kant and his school, a number of philosophers and theorists, in addition to those we have noticed, have appeared in Germany and France. Our readers may find the chief of them mentioned, and distinguished into schools, in the works of two living authors, to whom we have already referred.§ One of these authors, M. Lermnier, seems to make it a subject of reproach to England, that it has contributed so little

* *Forte fortuna, quam die quodam in ejus mensâ essem, laicus quidam legum peritus aderat; is nescio unde nactus occasionem, cepit accurate laudare rigidam illam justitiam, quæ tum illic exercebatur in fures, quos passim narrabat nonnunquam suspendi viginti in una cruce; atque eo vehementius dicebat se mirari, cum tam pauci elaborarentur supplicio, quo malo fato fieret, uti tam multi ubique grassarentur. Tum ego, (ausus enim sum libere apud Cardinalem loqui,) nihil mireris, inquam: nam hæc punitio furum et supra justum est, et non ex usu publico. Est enim ad vindicanda furta nimis atrox, nec tamen ad refrænanda sufficiens. Quippe neque furtum simplex tam ingens facinus est, ut capite debeat plecti, neque ulla pœna est tanta, ut ab latrocinii cohibeat eos, qui nullam aliam artem quærendi victus habeant.—Utopia, lib. i.*

† Hume, *History of England*, vol. v. p. 533.

to theoretical jurisprudence.* Until very lately, Bentham appeared almost alone to remove the reproach, and he is open to objection for his strong utilitarian views and principles, and for his disregard of and contempt for all past experience. For our own parts, we can scarcely consider this dearth of speculative writers in England as a subject of regret. In too many instances, the modern principles which have been broached, are either very unsound, or very fanciful; and where this is not the case, we question whether the science of jurisprudence, or legislation, has derived much benefit from the labours of the writers in question. The love of system and method, however, which has given birth to or been engendered by this philosophizing spirit, has been attended with one remarkable effect in recent times. We allude to the rage for codification, which took its rise in the latter part of the last century, and which has led to a general revision and systematic arrangement of their laws in codes, by several of the governments of Europe. The subject of codification engaged the attention of the principal lawyers of Germany, in a remarkable controversy which took place among them about the year 1815. The immediate subject of discussion concerned the propriety of making one general code for the whole of that country. MM. Thibaut and Savigny, professors of law at Heidelberg and Berlin respectively, were the leaders on either side, the former in favour of such a code, the latter against it. Savigny's views upon the subject are contained in a little work, which he entitled the *Vocation of the present Age for Legislation*. This, like every other work of the same profound writer, has met with a very extensive and favourable reception. A translation of it into English has been written and privately printed by a learned member of the English bar. On the question of codification at large, Savigny considers that, in a general revision and consolidation of the laws of a state, codifiers too often lose sight of, or are unable to trace, the true motives and reasons which led to each particular enactment, and that in endeavouring to arrive at an ideal perfection, they are too apt to neglect the peculiar wants, feelings, and customs of the people whose laws it is proposed to remodel and systematize. What though there be some confusion and difficulty, (affecting chiefly the regular professors of the art or science of law,) arising from the variety of customs prevailing in the different provinces of an empire, added to the multiplicity of the laws themselves. Such a state of things is not inconsistent with prosperity and order, with happiness and justice, among the people at large. But these blessings might be endangered by a rash attempt to introduce simplicity and uniformity, on the part of those who are presumptuous enough to imagine themselves competent to provide, at a single stroke, for the multifarious exigencies, which had singly demanded all the care, vigilance, and abilities of generations of bygone statesmen. If ever a measure, of such vast extent and importance, as a new general and uniform code for a large empire, is at all likely to be attended with happy results, it is when the science of jurisprudence has attained its very highest point of perfection, and when men are found fitted for the task of codification, by the greatest abilities and the most profound knowledge, historical, philosophical, and practical, of the

Law. whole subject submitted to them. These qualifications were not sufficiently possessed by the compilers of the three principal codes of modern times, those namely which were in force at the time when Savigny wrote the treatise above referred to,—the French, the Austrian, and the Prussian codes. Savigny considers them to have been signal failures, and the influence which they exerted on legislation, he thinks, was any thing but salutary. Of late, the rage for wholesale codification seems to have subsided in a great measure.

English
legislation.

29. In our own country, which has always been distinguished for its sober good sense and distrust of abstract theories, no universal revision of our laws has been attempted in the way of a general code. Bentham, indeed, who entertained any thing but respect for the jurisprudence of his country, vehemently urged the necessity of a totally new code for England, and proposed that the duty of compiling one should be intrusted to a foreigner! But very few, we imagine, could be found to second him in such a scheme. In the mean time, however, the task of consolidation and revision has been carried on in England, in a much more safe and wholesome manner; not by pulling our system to pieces under pretence of imparting to it an appearance of greater regularity, and dressing it up in what might be considered a more scientific form, but by taking up successively different branches of our law, expunging what is obsolete or useless, curtailing redundancies, supplying what is manifestly wanting under those heads, and arranging the rules under them in a better order. Whatever exception may be taken by self-styled philosophers to our laws and constitution, as an unsightly and unscientific mass of heterogeneous materials, not only have those laws and that constitution been productive of unexampled prosperity and happiness at home, but for a length of time they have been so largely the theme of admiration, and the object of imitation to foreigners, that English jurisprudence must form a prominent object of attention to the general lawyer. On this account, therefore, in addition to a just national predilection, English law, though a private national system, deserves a place in an Article like the present. Before, however, we proceed to notice any of the positive systems we have alluded to above, we propose to give a very brief consideration to the philosophy of law, chiefly with a view to explain what we conceive to be the true grounds upon which all human law and legislation rest; a subject, which, though frequently abused by sciolists, and therefore sometimes liable to suspicion and distrust, is nevertheless of deep interest and momentous importance. Without further preface, we shall now proceed with that part of the subject.

CHAPTER I.

THE PHILOSOPHY OF LAW.

Sect. 1. *Of the Nature of Laws in general.*

A law in its
most gene-
ral sense.

30. Various definitions have been given of a Law by different writers; as, a Rule of action;* a Necessary Relation arising from the nature of things;† &c. But whatever definition we may accept, a law, in its most extensive signification, involves two essential properties, generality and necessity. A law is general, inasmuch

as the mode of action or relation which it implies, is not confined to a few objects or a single occasion, but embraces a number of objects, and operates constantly and uniformly. By the second property, we understand that this general relation or systematic mode of action is not the effect of chance, nor spontaneously or capriciously adopted by those who observe it, but that it is produced by some external necessity or coercive power prescribing the relation or form of action, and compelling its observance. We may once more refer to Hooker's definition given at the commencement of this Article, (No. I.) as containing, perhaps, the most general, and, at the same time, the most exact description of a law with which we are acquainted.

Law.

31. Much discussion, and, as it appears to us, much verbal trifling, has been expended to little purpose, by some recent writers, in endeavouring to fix with precision the degree of generality necessary to constitute a law, in what they consider to be its only strict and proper sense. We shall, however, give the result of their ex-cogitations, so far as we think them worthy of remark. A law, in its only proper sense, say these writers, by which they mean a law imperative, or a mode of conduct prescribed by one intelligent agent to others, must be strictly general, in the two respects mentioned in the preceding paragraph. First, it must apply to a large though indefinite number of individuals; and although it may allow of numerous and extensive exceptions, although not only single individuals, but even large classes placed under the authority of the same lawgiver, may be privileged to be exempt from its observance, a law must be so general, in respect of its objects, as to form the rule, and not the exception. Secondly, it must prospectively have a perpetual or rather indefinite duration; it must not even be temporary, much less limited to a special occasion. When either of these requisites be wanting, call the prescribed rule what you will, it is not, they assert, a law. They profess to determine, in the following manner, the names properly applicable, where that of law is improper. When a mode of conduct is prescribed to all or the greater part of the members of a community, but on a special occasion only, it is an *Order*. When it is prescribed, though perpetually, to one or a few comparatively out of the whole number of members of the community, it is a *Privilege*, as the Roman jurists would have understood the term, for we have none exactly answering to it. Lastly, when not only the occasion is special, but the number of persons affected is limited, the order or privilege is narrowed into a simple *Command*.

32. So far with regard to the generality of a law. Various What we have above designated by the general name of necessity, is of various kinds; and laws may primarily be classified according to the particular species of necessity which occasions them. Thus there is a mathematical necessity, on which depend the general relations, or laws, of numbers, lines, spaces, &c. Again, there is a physical necessity having for its objects passive agents, and giving rise to the various physical or material laws of the universe. We however are concerned with a different species of necessity, that namely which is applicable to moral agents only; which directs and influences their conduct, without absolutely coercing their will or destroying their freedom; and which is commonly known by the name of *Obligation*. Upon this moral necessity depend all the laws, human and divine, by which man, considered as a rational and conscious

Obligation.

* Blackstone, *Commentaries*, vol. i. p. 38.

† Montesquieu, *Spirit of Laws*, book i. ch. i.

Law.

being, is governed. Burlamaqui has written so clearly, and so much to the purpose, upon this topic, though with some slight drawbacks, that what he has said may not upon the whole be unacceptable to our readers. "When we mention necessity," he says, "it is plain we do not mean a physical, but a moral necessity, consisting in the impression made on us by some particular motives, which determine us to act after a certain manner, and do not permit us to act rationally the opposite way."

33. "Finding ourselves in these circumstances, we say we are under an obligation of doing or omitting a certain thing; that is, we are determined to it by solid reasons, and engaged by cogent motives, which, like so many ties, draw our will to that side. It is in this sense a person says he is obliged. For whether we are determined by popular opinion, or whether we are directed by civilians and ethic writers, we find that the one and the other make obligation properly consist in a reason, which, being well understood and approved, determines us absolutely to act after a certain manner, preferable to another. From whence it follows, that the whole force of this obligation depends on the judgment by which we approve or condemn a particular manner of acting. For to approve, is acknowledging we ought to do a thing; and to condemn, is owning we ought not to do it. Now *ought* and *to be obliged* are synonymous terms."

34. "We have already hinted at the natural analogy between the proper and literal sense of the word *obliged*, and the figurative signification of the same term. Obligation properly denotes a tie; a man *obliged* is therefore a person who is *tied*. And as a man bound with cords or chains cannot move or act with liberty, so it is very near the same case with a person who is *obliged*: with this difference, that in the first case, it is an external and physical impediment which prevents the effect of one's natural strength; but in the second, it is only a moral tie, that is, the subjection of liberty is produced by reason, which, being the primitive rule of man and his faculties, directs and necessarily modifies his operations in a manner suitable to the end it proposed."

35. "We may therefore define obligation, considered in general, and in its first origin, a restriction of natural liberty, produced by reason; inasmuch as the counsels which reason gives us are so many motives that determine man to act after a certain manner preferable to another."*

Reason and conscience. 36. The only fault we find with this clear statement is, that here, as elsewhere in the same work, Burlamaqui seems to give a somewhat undue preference to human reason over conscience. The *sense* of obligation, which forms a distinct subject of consideration from the *nature* and *origin* of obligation viewed objectively, may be presented to the mind in either of two ways—by reason or by conscience—and in either way may produce its due effect. By reason, we not only conclude that a certain line of conduct is our duty, but we arrive at that conclusion by a rational process; and in consequence of having first satisfied ourselves of the existence of some adequate cause to make that line of conduct obligatory upon us, we distinctly see that the observance of such conduct tends to our good, and therefore we conclude that we ought to observe it. Conscience, on the other hand, simply judges a thing to be right, without con-

Law. sidering or inquiring how or why it becomes a part of our duty. Reason and conscience have each had their advocates among moralists; of whom some have chosen to name reason, and others conscience, as the sole or chief guide in moral conduct. Neither reason nor conscience, however, should be exclusively favoured: each of them in its proper place has its distinct function to perform. At the same time, we cannot for a moment hesitate which of those classes of moralists ought, in our estimation, to be preferred. In all the more important questions relating to our moral conduct, conscience is the safer and the better guide: it is less liable to be deceived, and exercises a more salutary influence than reason.

37. The question, however, with which we are now Their pro- concerned, is not what should be the practical test and per office, criterion of duty or right, in matters of difficulty and doubt; nor whether, or in what respects, we ought, as a general rule, to obey the dictates of either reason or conscience, or both. At present we have to consider, philosophically, the ground and cause of that obligation, which, whatever be the sentiments of those whom it affects, imparts to law its real force and efficacy. Let it then be remembered,—in order to separate two distinct questions, frequently confounded,—that reason and conscience are simply informants, and nothing more; that, as such, they are not infallible; but that each of them is liable occasionally to be impaired, abused, or deceived. When we say that our conscience or our reason deceives us, what do we mean? We mean that it makes a false representation; either that it suggests the existence of an obligation to do a particular act, where no obligation really exists; or that it represents an act as improper or indifferent which we are under an obligation to perform. Our conscience and our reason, therefore,—whatever may be their absolute or relative value as guides and informants,—can never, properly speaking, *create* an obligation; they can never make that to be intrinsically right, which is essentially wrong. Obligation and right, it may not be improper to remind our readers, are here considered objectively.

38. Keeping the above distinction in view, we must look for the philosophical ground and reason of obligation beyond and independently of any persuasion or feeling entertained by the person obliged respecting his duty. The true reason of obligation, then, is implicitly contained in the fundamental axiom in moral science, that every rational being is bound to consult his own true welfare and happiness. This proposition, properly understood, is an ultimate truth which does not admit of discussion or proof. The only question can be respecting the application of so strong a term as *obligation* to the expediency of acting in accordance with one's interest. But surely no term can be too strong, which is intended to express the reasonableness, the propriety, of choosing happiness, or the gross folly of wilfully abandoning it, when attainable by us. As such an abandonment, on the part of a free agent, would imply a forfeiture of his claim to be regarded as a reasonable being, so long as he sustains that character, he may, without much impropriety, be considered to be *tied down* to the choice of happiness. An obligation therefore supposes, first an action proposed to a free agent, for his voluntary observance; secondly, some consequence of good or evil, connected with that action; either a good consequence, as the reward of his compliance with the proposed condition, or an evil consequence, to punish

* *Principles of Natural Law*, part i. ch. vi. sec. 9.
VOL. II.

Law. him in case of non-compliance. The consequence, good or bad, must be such as the agent cannot of himself otherwise command or avoid; and it is called the **Sanction of law.** *sanction*. It may, we see, be either a reward or a punishment. Some jurists, indeed, contend that the latter only can properly constitute the sanction of a law; but as the attainment of a positive good affords as rational a ground, and, in many cases, as efficacious a motive, for directing the agent in the choice of his conduct, as the avoiding of a positive evil, we feel fully warranted in classing rewards amongst legal sanctions. Whether, under particular circumstances, punishments may not be preferable to rewards, with a view to effect the main purpose for which positive laws are instituted, is quite a distinct question, and one into which we decline entering at present. In another aspect, the attainment or the loss of a good may be regarded, respectively, as the avoiding or the incurring of an evil; and in this way, sanctions of both species may be reduced to a single class.

Errors of utilitarianism. 39. The connection, however, between interest and duty, though rarely questioned, is apparently regarded by some moralists, of a high order too, as accidental rather than essential. Their disinclination to adopt, fully and explicitly, the doctrine of obligation as above stated, may be ascribed, in a great measure, to the prevalence of two dangerous errors in connection with that doctrine, and to their wish to discountenance them. The first error assumes that no obligation, however solemn, ought to be recognized as such until the sanction be perceived, and the force of the obligation actually proved. Not content with establishing interest as the true and only basis of obligation, the holders of this opinion seem to require that motives of interest should always be present and uppermost in the mind. Any faculty, which enables us to apprehend moral truth, without going through the preliminary steps requisite to satisfy our purely intellectual inquiries, is apparently treated by them as fallacious. So that they not only would destroy one of our most useful faculties, conscience, but would necessarily confine all duties within the narrow limits of each individual's own weak and fallible intellect. This is one of the worst errors into which Paley and others of his school have fallen. Or if he is not justly chargeable with this error in its full extent, he has at least spoken of conscience in terms so disparaging as to convey the impression that it ought to be disregarded as a worthless prejudice.* We have already endeavoured to show the distinction between the ultimate reason and the practical apprehension of obligation; a confusion between these two has in no small degree given birth to the error here pointed out.

Motives of expediency. 40. The other error consists in partial and inadequate conceptions of true expediency, which is confined, for the most part, to advantages of an inferior order. Paley endeavours to obviate any objection on this head, by defining obligation to be a *violent* motive or inducement. This however does not afford a complete or accurate explanation of the matter, and his use of the word *motive* is calculated to mislead. On the one hand, obligation,—unless we would affix a purely arbitrary meaning to the word, as expressive merely of a certain though indefinite amount of expediency,—is susceptible of every degree of strength, from the lowest to the highest we can imagine. It would be no less unphilosophical than

untrue, to deny the reasonableness, and therefore the obligation, of endeavouring to procure even a slight good, where the pursuit of it does not interfere with the attainment of a higher good. All that can be said in such a case is, that the obligation is less stringent indeed, but not on that account the less reasonable. On the other hand, a particular inducement, viewed separately and apart from ulterior considerations, may be extremely violent, without affording any true and rational motive for action; as where there are conflicting inducements of a still more powerful nature, suggesting a contrary line of conduct. In such a case, reason would suggest the propriety, and therefore the obligation, of pursuing that course which is sanctioned by the most powerful inducements. An obligation, therefore, may be distinguished from a simple motive, however violent: strictly speaking, we should estimate the former from a consideration and comparison of all the separate consequences, good and bad, present and future, attending the action which it involves. The obligation consists in the resulting motive of all such consequences. In the case of our most important obligations, indeed, there are consequences so momentous and overwhelming that, in comparison with them, all inferior inducements may safely be disregarded. To conclude, any theory of obligation must necessarily be false which adopts a low and incomplete standard of expediency.

41. We have now sufficiently explained the nature of obligation, or that moral binding power which is derived from the existence of a sanction. A sanction may be specially annexed to a single prescribed action, and so create a special obligation. It is only where it is generally and permanently annexed that we have a law.

42. But in order to render a law operative, a third condition, besides generality and obligation, is required, viz., that the law be promulgated or made known to those who are to be bound by it: first, with regard to the rule, as distinguished from the obligation. This being the standard and measure by which they are to regulate their conduct, an accurate knowledge of it is indispensably necessary; otherwise they would be left in the dark how they ought to act. But with regard to the sanction, a far less precise knowledge will often suffice. A simple persuasion of duty, without any attempt to investigate its cause and nature; a knowledge of the existence of some superior agent, with the will and power to reward or punish the observance or breach of the law; or even a general and indistinct apprehension of some impending but undefined good or evil, connecting itself with the rule, may be, and often is, sufficient to influence the agent, and dispose him to compliance. The modes and instruments used for imparting a knowledge of laws and of their obligations are various; but the examination of these belongs rather to the discussion of the different species of laws than to the abstract description of law in general.

43. A law is commonly distinguished from some other things, which bear a near relation to it: 1. From *counsel* or *advice*; which is the communication of a binding precept by one who has no share in imposing it; 2. From *covenants* and *contracts*; which are made between equals, and do not suppose any superiority to reside in either of the parties over the other; 3. From a *liberty*, or simple *permission*; which, however, is often confounded with a *right*. These distinctions relate chiefly to positive laws. Some jurists have

* *Moral and Political Philosophy*, book i. ch. v. &c.

Law.

taken the trouble of discussing whether a simple permission be an effect, or a mere negation, of law. Those who hold the former opinion, sometimes make a distinction between Preceptive and Concessive law. The preceptive part is the law properly so called: it includes the whole of the commands and prohibitions of the lawgiver. The concessive law marks the extent of the subject's liberty. A liberty implies, simply, indifference on the lawgiver's part: it does not necessarily include protection for its exercise. When protection by the lawgiver is added to either a liberty, or a duty, the latter becomes a right. It is a liberty or a duty, in relation to the lawgiver. It is a right, as against those who are prohibited from interrupting its exercise or performance. As they are prohibited by means of legal obligations, right and obligation are correlative.

A liberty distinguished from a right.

Sect. 2. Of Necessary Laws.

Laws either necessary or positive.

44. Having explained the chief properties of all laws in general, we next distinguish their several kinds. And first, laws are either Necessary or Positive. Necessary laws are those inevitable relations of right which must exist in the very nature of things, and which cannot be ascribed to the institution of any lawgiver. Some writers, indeed, contend, that the name of laws cannot properly be applied to such: however, we have Hooker's authority for our application of the term. "They apply the name of law unto that only rule of working which superior authority imposeth; whereas we, somewhat more enlarging the sense thereof, term any kind of rule or canon, whereby actions are framed, a law."* Positive laws are artificially instituted by a lawgiver; and they are occasionally designated by such names as *arbitrary*, or *voluntary*, implying that they were established at the will, as well as through the power, of the lawgiver.

Discordant opinions respecting the division and nomenclature of laws.

45. No small difficulty and confusion have been occasioned by the disagreement of jurists, not only respecting fundamental principles, but also with regard to the nomenclature and division of laws. The most common primary division is into Natural and Positive. The term *natural law*, however, is ambiguous, the same writers frequently using it in different senses. The meaning of it which most nearly combines the various significations generally attributed to it, is that law which, antecedently to all human institutions, is binding on the whole of mankind. So far most authors are agreed; but in other respects, where this law is in question, many points of difference are observable among them. Several writers—and Grotius is of the number—make the law of nature to be the supreme law of all, and regard it as purely necessary, or independent even of Divine institution.† The great jurist just named distinguishes natural law from a Divine positive law;‡ but then he mixes up the former with many principles peculiar to mankind; thereby proving that his natural law partakes of both the *Eternal* and the natural law of Hooker. Hooker's Law of Nature is subordinate and specific, being that particular modification of the Law Eternal (or supreme necessary law) which the Almighty has adapted to the state of man.§ The most common idea of the law of nature regards it as of Divine institution: consequently, when so regarded, it is in strict-

ness deemed to be positive, because instituted by God; and, therefore, when it is opposed to positive law, the latter must be understood to mean *human* positive law. But then, with some inconsistency, a third species of law is introduced, and opposed in turn to each of the others: viz. a Divine positive law, not natural. The Roman jurists understood the law of nature in a different sense from any of the above, for with them it included the brute creation.* Lastly, some modern writers, bewildered amongst all these conflicting meanings, cut the matter short by denying that there is any such thing at all as the law of nature. An illogical division of the subject matter has occasioned much of the confusion in the question. With a view to avoid it, we have adopted division stated at the commencement of this section. We shall class the law of nature, then, amongst positive laws, giving it a limited meaning, and, with Hooker, regarding it as a positive, or artificial modification of the necessary law, which is the supreme rule, not only of mankind, but of all moral beings. To this necessary law our attention must now be specially directed.

Law.

46. In one respect, every law is necessary; that is, In what respect a law is said to be necessary. as it affects those who are subject to it; for as they cannot, at their pleasure, command the reward, or evade the punishment, which constitutes the sanction of the law (No. 38), they are under an unavoidable or necessary obligation to observe it. In the case of positive laws, this necessity extends no further: the good or evil of the sanction has no necessary or inevitable connection with the law beyond the pleasure of the lawgiver, who may repeal the law by withdrawing the sanction. But the necessary laws, of which we now treat, cannot be so annulled. Their sanctions are, in relation to every moral being without exception, the inevitable consequences of certain actions, or rather, we should say, of certain active habits and dispositions, involving the unalterable and essential laws of morality, and constituting the fundamental rule of right.

47. The existence, however, of necessary laws has not always been asserted in sufficiently clear and distinct terms; occasionally, too, it has been called in question. We do not now allude to such writers as Hobbes, who holds that "we ourselves are the authors of the principles of justice, of right and wrong, by making those laws and compacts whence the measures of justice are taken: since before any such laws or compacts were instituted, there was no such thing as justice or injustice, public good or evil, among men, any more than among beasts." Assertions of this kind are scarcely deserving of serious refutation. Those whose opinions upon such matters are really entitled to respect, agree in recognizing some paramount and invariable law, or rule of justice, independent of and superior to all human institutions and opinions. The only question is respecting the source of this law. A practice has very extensively prevailed of ascribing it, in terms at least, to an arbitrary or positive institution of the Almighty, as if it were within the range of possibility for him to have approved of or sanctioned another and different rule. One slight observation will go far to place the matter in its true light. The very practice of styling God *just* and *good*, shows that we acknowledge some original and independent principles of

The existence of necessary laws asserted,

* Jus naturale est, quod natura omnia animalia docuit. Nam jus istud non humani generis proprium; sed omnium animalium, quæ in terra, quæ in mari nascuntur, avium quoque commune est.—Dig. I. i. l. 3.

Law. justice and goodness. Leibnitz remarks, that justice would not be an essential attribute of the Deity, if he by Leibnitz, had established it by an arbitrary decree of his own. Justice, he adds, observes laws of equality and proportion as certain and unchangeable as those of arithmetic and geometry. Hooker speaks to much the same effect. In treating of the Law Eternal, as of that law which God himself observes, he remarks, "that counsel is used, reason is followed, a way observed, constant order and law is kept." "They err, therefore, who think that of the will of God to do this or that there is no reason besides his will. Many times no reason known to us; but that there is no reason thereof, I judge it most unreasonable to imagine." And he concludes the first book of the *Ecclesiastical Polity* with that noble, but now somewhat trite passage, wherein he says of law, that "all things in heaven and earth do her homage, the very least as feeling her care, and the greatest as not exempted from her power."* Expressions such as these, sufficiently indicate Hooker's recognition of one essential, necessary law; and we are left to infer that, had not God chosen and observed it, he would not be the reasonable, good, and perfect Being that he is.

by Grotius. 48. The emphatic language of Grotius should not be omitted here. No writer we are acquainted with has been equally explicit on this topic. After maintaining, against Carneades and all such objectors, the immutable character of right, and its nature as it applies to man, he adds, that "all he had said would take place, though we should even grant, what without the greatest wickedness cannot be granted, that there is no God, or that he takes no care of human affairs." We have already (No. 45) pointed out the sense in which Grotius understands the law of nature, which, we have also stated, he distinguishes from a voluntary Divine law. The latter, he says, "does not command or forbid such things as are in themselves, or in their own nature, obligatory or unlawful; but, by forbidding it, renders the one unlawful, and, by commanding, the other obligatory." But, "the law of nature," he shortly afterwards adds, "is so unalterable, that God himself cannot change it. For though the power of God is infinite, yet we may say that there are some things to which this infinite power does not extend, because they cannot be expressed by propositions that contain any sense, but manifestly imply a contradiction. For instance, then, as God himself cannot effect, that twice two should not be four, so neither can he, that what is intrinsically evil should not be evil."†

49. Those who, without fully comprehending the meaning of Grotius, and startled by his decided language, have objected to his view of the subject, when they come to reason upon it, cannot help arriving at the very same conclusion with him. Puffendorf does so, apparently,

* *Ecclesiastical Polity*, book i. secs. 2, 15.

† *De Jure Belli et Pacis*, ubi supra. It would be superfluous to multiply authorities to establish what perhaps is already sufficiently evident. But we cannot forbear noticing that the profound Bishop Butler hints at the existence of similar moral impossibilities. "Why the Author of nature does not give his creatures promiscuously such and such perceptions, without regard to their behaviour; why he does not make them happy, without the instrumentality of their own actions, and prevent their bringing any sufferings upon themselves—is another matter. Perhaps there may be some impossibilities in the nature of things which we are unacquainted with." *Analogy of Religion Natural and Revealed*, ch. ii. See also, Burlamaqui, *Natural Law*, part 2, ch. v. sec. 5.

without being aware of it.* He felt alarmed, it seems, because he imagined that Grotius favoured the idea, that without supposing a Divine Creator, there could have been room for the actual exercise of the necessary law. But Grotius contended for no such thing. He contended only for necessary *relations* of right and wrong. His meaning is identified with that of Montesquieu, who says, that "before [positive] laws were made, there were relations of possible justice. To say that there is nothing just or unjust, but what is commanded or forbidden by positive laws, is the same as saying that before the describing of a circle, all the radii were not equal."† In other words, he meant, that wherever Omnipotence interposes, and establishes the requisite conditions for the possible breach or observance of the necessary law under any particular form,—wherever God creates free agents, endows them with moral and intellectual faculties and perceptions, and places them in juxtaposition with objects of the same nature with themselves, towards whom it is in their power to exercise benevolence, justice, truth, &c., and without whose existence and presence it would be impossible for them to exercise those virtues,—there nothing further is required on the part of God to determine in general what shall be right or wrong; for that it would be impossible, in the very nature of things, for any exertion of power to annex moral happiness, and therefore an obligation (No. 38), to the habitual exercise of malevolence, injustice, and falsehood; or moral misery,—involving its inevitable consequence, wrong,—to benevolence, justice, and truth.

50. Of the virtues here named, and assumed as constituting the essential relations of right, no one will feel disposed to question the intrinsic excellence and paramount obligation. Yet we do not consider the preceding discussion by any means superfluous. By having a clear and definite knowledge of the foundation of our duty, we are enabled to form a better estimate of the stability and just proportions of the superstructure; many difficulties, otherwise wholly inexplicable, are accounted for; Divine wisdom and justice are vindicated by the removal of all suspicion that we are subjected to a law capriciously chosen; we become satisfied that there is, that there must be, one paramount rule, absolutely binding upon us and all moral beings; a rule which it is of the highest moment that we should observe, which no power can surmount or annul, and which therefore offers an end worthy of the greatest efforts of Divine and human wisdom, labouring to establish the supremacy of that law in and over us. Having fully satisfied ourselves of the reality and nature of that law, and taken it as the basis of all our obligations in particular, we can the more readily disembarass ourselves of the many groundless theories with which the science of jurisprudence has been encumbered. But first we should observe, if any such observation is now required, that the necessary moral law strictly fulfils all the conditions of a law enumerated in the preceding section. Its obligation we have already shown to be necessary and essential. That it is more than general—that it is universal—follows from its essential character. With regard to its promulgation, whatever occasional mistakes and misapprehensions may occur respecting its

* *Law of Nature and Nations*, book i. ch. ii. sec. 6; book ii. ch. iii. sec. 4.

† *Spirit of Laws*, book i. ch. i.

Law.

application in particular cases, there is no reasonable human being so devoid of moral sense, as not to feel its paramount obligation, without any formal announcement of it to him. It is on this latter account that it is frequently styled *natural*; though, as we have stated, we reserve that term for one particular and positive form of it.

Man necessarily a social being.

51. A particular consideration of the *social* character of the necessary obligations of benevolence, justice, and truth, will serve to remove the charge of selfishness, sometimes, though without much reflection or justice, brought against the account of obligation, which takes interest for its basis. (No. 38.) Recollecting how large and important a share of our duty is included in the obligations we have named, and how, in their very nature, they imply that our immediate regards should be fixed on others, and therefore withdrawn from self, all objection of the kind alluded to ceases. A like consideration enables us to expose the very imperfect, and therefore false, view, not unfrequently taken of the ultimate end and purpose of human societies and laws; a view, which regards the ends of government to be merely temporal, and intended only for protection against the material wants and dangers to which man is exposed in a state of unassisted nature. It is true, that the existence of such evils furnishes the immediate occasion for the institution of temporal government, and that one important end of the latter is protection against them. But this is not all. The social nature of man is not a mere accident of humanity; it belongs to him essentially, as he is a moral being; and sociability is enjoined as an indispensable part of the necessary law, because it is inseparable from the cultivation and exercise of benevolence, justice, and the other social virtues. In the more complete and correct view of the subject, human laws are subsidiary to the necessary moral law; and the material wants of man are only so many artificial bonds, for uniting our species in a society which is designed to be matured into one of a superior nature.

Sect. 3. Of Positive Law in general.

Standard of perfection.

52. The necessary, or, as we may now call it, the moral law, furnishes the only true ultimate standard of right. And that standard, though there are various degrees of approximation towards it, cannot itself stop short of absolute perfection. Now moral perfection implies a complete and spontaneous accordance with the high requisitions of the moral law: it is not enough that the outward actions be right: the principles and motives must be so too; the moral taste and disposition must be so entirely in harmony with the dictates of the highest morality, that no suggestion, either of reason or of conscience, much less any external compulsion, can be required, as an incentive to habitual active good.

Positive law a process of moral regulation.

53. So far with respect to the standard of right. We have next to regard man as a moral being, whose proper aim, therefore, is his perfection, and whose duty it is to make the nearest practicable approach towards it. The natural or ordinary processes, which may be put in action for promoting his moral advancement, comprehend the regulation of his spirit and inward principles, and the regulation of his outward actions. It is the former which it is proposed ultimately to affect; but though a direct appeal may, in some measure, be made to them; yet this cannot be done effectually without the concurrent regulation of his external conduct. The converse of this is also true; that is to say, even supposing there

Law.

were only some subordinate object, depending on man's outward actions, in view, such as his temporal welfare, this object could not be promoted in any tolerable degree, by simply attending to his conduct, without at the same time endeavouring to guide his principles. Thus there are two essential processes, distinct, though intimately related. They are distinct, not only in their immediate objects, but in the instruments they employ, and the methods they pursue, and they require distinct agents to put them in motion, though their ultimate aim be directed to one common point. In civil society, the regulation of the inward principles belongs to the Church; that of the outward actions,—in those respects, at least, where the standard of conduct is rendered compulsory,—to the State. *Government*, in a somewhat enlarged sense, may be considered to embrace both departments, as subordinate and necessary branches of the same whole, its ultimate object being to promote, chiefly and principally, the moral welfare of the community over which it is set.* Having premised so much, our attention must now be directed to outward actions, and to positive law, which comprehends the rules framed for regulating them.

54. Positive law is a rule of conduct, instituted by a lawgiver, and enforced by artificial sanctions.

55. I. Positive law is *instituted*. It therefore presupposes a lawgiver or sovereign; and this suggests a question respecting the right in general of imposing laws, or the right of sovereignty. As an abstract proposition, this right is commonly stated to depend upon the possession of the three qualities necessary for good government; namely, wisdom to discern the real interest of the governed, and the best mode and means of promoting that interest; goodness, to dispose the sovereign to pursue those means; and power to apply them effectually. The application of this principle to establish God's right to the government of mankind is easy enough; for granting that he possesses the three qualities here mentioned, it follows that his government cannot be otherwise than beneficial in the highest degree to man, who is therefore morally bound to submission, inasmuch as he is bound to pursue his highest interest. And obligation and right being correlative, (No. 43.) man's obligation to submit, involves God's right to govern. It would be absurd to reduce God's right of government to his supreme power alone, though such an opinion has occasionally been put forward; for could we suppose the case of a being of transcendent power imposing laws unnecessarily severe and unjust, he must of necessity be an evil and malignant, not a good being; and as he could not change the eternal laws of right, nor oblige beings of less power to any course morally injurious to themselves, his right could not extend to any unjust exertions of power, which are mere

Institution of positive law.
Right of sovereignty.

* Our greatest political philosopher, Burke, observes, "An alliance between Church and State in a Christian Commonwealth is, in my opinion, an idle and a fanciful speculation. An alliance is between two things, that are in their nature distinct and independent, such as between two sovereign States. But in a Christian Commonwealth, the Church and the State are one and the same thing, being different integral parts of the same whole." See the whole passage in his works, vol. x. p. 43. ed. 1818. The reader will find the same idea more fully expanded in Coleridge's essay *On the Constitution of the Church and State, according to the Idea of each*, and in Mr. Gladstone's Treatise, *The State in its Relations with the Church*. Cicero, it may be observed, dwells especially, and with more than his ordinary force and eloquence, on the moral purpose of law and civil government. *De Legibus, passim*.

Law.

tyranny. We can therefore admit no such modification of the principle which establishes wisdom, goodness, and power, as the three essential elements of the title to sovereignty.* How to apply this principle, however, to human potentates, is much more difficult; but at present we shall not enter into the question as applicable to them. Only we may observe that rightful human authority is a *moral* right, or, still more strictly, a *natural* right, because it precedes human law, and generally arises upon a state of circumstances, which happen in the ordinary course of human affairs, and without the device and contrivance of man.

Positive law concerns specific actions.

56. II. Positive law is a rule of *action*; it "appoints the form and measure of working." In this respect it is distinguished from moral law, which is not restricted to any specific mode of action, but inculcates, as a principle, the performance of right, and the abstinence from wrong, universally, and under all circumstances, but without particularizing any of such circumstances. We need not here repeat what has been said on this topic, in the first paragraph of this article. At present we must observe, that positive law, having to deal with the baser part of our nature, applies itself exclusively to the coarser and more mechanical department of our moral training, namely, the regulation of our *conduct*. Because it would be useless to lay the abstract truths and principles of morality before rude and untutored beings whom it is necessary to compel, it embodies those principles in some selected and definite form, and prescribes rules of conduct more or less specific. The natural order of progress in practical morality is from single actions to habits, from habits to principles, and from principles to a confirmed disposition. Positive law having guarded the outward and visible conduct of man, and having laid the foundation of right habits, in the most ordinary and obvious cases, can do no more. It is the business of other and higher appliances, and of self-regulation, to confirm, enlarge, and mature those habits into a settled principle of right.

Artificially enforced.

57. III. Positive law is enforced by artificial sanctions. The potency of a sanction, as theoretical writers inform us, depends on four circumstances, the intensity of the good or evil it involves, its duration, its certainty, and its proximity in point of time. With regard to the first three, wherever they can be known and measured, they afford a fair test for estimating the genuine degree of obligation, and therefore they ought, in reason, to possess an influence proportioned to their amount. It is otherwise with regard to the last. We can only allege the frailty and imperfection of man as the cause of those remarkable differences which are observable, in the present power of sanctions over him, proportioned to their relative proximity or remoteness. "Whatever withdraws him from the power of the senses, whatever makes the past, the distant, or the future, predominate over the present, advances him in the dignity of thinking beings." But this power of realizing what is distant, does not belong to him in his natural state, nor is it readily attainable. Hence the sanctions of the moral law, which are commonly supposed to be remote, lose much of their just influence; and, in a multitude of instances, it would be unable to act upon man, without the artificial institution of more immediate sanctions. The compa-

rative violence with which the latter act, gives them, in a measure, the character of compulsion; but this is a moral and not a physical compulsion: man is still left a free agent, and the feeling of restraint occasioned by the trammels of positive sanctions will gradually subside, in proportion as he rises to the influence of higher motives.

Law.

58. As to the subject-matter of positive laws, they may include any human actions, those which terminate in the person himself, as well as those which affect others. Subject-matter of positive laws.

It would be impossible, however, by any abstract rule, to assign the just limits of legal enforcement. "To distinguish," says Mr. Austin,* "the acts and forbearances that ought to be the objects of law, from those that ought to be abandoned to the exclusive cognizance of morality, is, perhaps, the hardest of the problems which the science of ethics presents. The only existing approach to a solution of the problem, may be found in the writings of Mr. Bentham. (See, in particular, his *Principles of Morals and Legislation*, ch. xvii.)" Mr. Bentham, however, has not solved the problem, and for the simple reason, that it does not admit of a general solution: the selection of topics for enforcement depends upon a number of circumstances constantly varying. There are some obligations and rights, indeed, so obvious and clear, and so necessary to be observed and respected, that there can scarcely ever be a question about the propriety of enforcing them. Jurists have distinguished such by the name of *perfect* obligations and rights.† There are others, of a more refined morality, not less certain it is true, at least in the apprehension of a sound moralist, but unsuitable to be extorted by force: these are called *imperfect*. But there is no well-defined line separating the two sorts of obligations and rights. The progress of society and civilization has a tendency gradually to advance the recognised boundaries of perfect obligations. We have a remarkable proof of this in the Law of Nations, a complicated system of acknowledged perfect obligations, but of modern growth. All laws, properly speaking, are of perfect obligation, since without sanctions they would not strictly be laws. However, the Roman jurists gave the name of *laws of imperfect obligation* to such imperfect rules as the legislator, accidentally or designedly, had omitted to provide with sanctions. Perfect and imperfect obligations.

59. A positive law must be sufficiently notified to those who are to obey it. But no general rule is laid down respecting the mode. The remaining conditions, commonly stated to belong to positive laws, are, 1. that they be *possible*, or such as the subject can fulfil; 2. that they be *just*, or conformable to the moral law, and the constitution of man; 3. that they be *useful*, or ordained, not simply for the sake of restraint, which would be unreasonable and tyrannical, but with a view, and in a manner, to secure some benefit or advantage to the subject on whom they are imposed.‡ Other conditions.

Sect. 4. The Law of Nature.

60. Having settled the general principles of law,—of moral or necessary law as the foundation of all other, and of positive law, as a means to an end,—our next business is to apply these principles to the Law of nature.

* Burlamaqui, *Principles of Natural Law*, part i. ch. ix.; Puffendorf, *Law of Nature and Nations*, l. 6. 10, 11.; 1 Blackstone's *Commentaries*, 40, 48.

† Puffendorf, *Law of Nature and Nations*, l. vii. 7. The expression, *sum jus*, used by Latin writers, denotes a perfect right.
‡ Burlamaqui, *Natural Law*, part i. ch. x. sec. 9.

Law. Nature in particular, or to that positive system which God has established for the government of his creature man, and upon which all human laws are built. The questions that we shall have to examine are, what the law of nature is; in what its obligation consists; how we become assured of its existence and reality, and acquainted with its rules; and how human laws connect themselves with it. But first in searching for a deter-

Meaning of the word natural. minate meaning of the word *natural*, amongst the various loose, and confused, and confusing senses in which different authors use that word, we cannot find a better explanation of its true meaning, than that given by Butler, who says that it signifies *stated, fixed, or settled*;* in which sense, it is opposed to what is commonly considered as supernatural or miraculous, because of rare or extraordinary occurrence. So that Natural Law, or the Law of Nature, will mean that stated, fixed law, which governs the human race, considered as one general community. It will appear, that, as a law, it possesses the two essential requisites of permanency and universality. (No. 31.) As the law of nature, its authority will be shown to be coextensive and coexistent with nature, or with the human race and the constitution of man in all ages. Again, it will be seen that, as a positive law, it possesses all the properties of such a law enumerated in the preceding section:— that it is instituted by God, with a view to perfect our nature; that it is most wisely and beneficently adapted for that purpose, first, by the definite form of its rules, as compared with the larger principles of the moral law, and, secondly, by the sensual character of its sanctions; in both these respects accommodating itself to human weakness. Lastly, it will appear to be sufficiently notified to all mankind. (No. 42.) Though this law be, in the highest degree, *possible, just, and useful*, (No. 59.) and though we are bound to receive it without questioning the wisdom, goodness, or power of Him who has ordained it, yet for any thing that we can know, or may observe in the law itself, God might have effected his purpose equally well, by a measure of a different form: the law of nature, like every other positive, or *arbitrary* (No. 44.) law, implies a certain choice of means on the part of the lawgiver, but without supposing that he could do violence to the end proposed by a wanton exercise of power. But though we must ascribe so much to God's power of choice, the indulgence in any speculations of what he might have done, can only lead to the most absurd results or perplexing confusion.† “Let us

then, instead of that idle and not very innocent employment of forming imaginary models of a world, and schemes of governing it, turn our thoughts to what we experience to be the conduct of nature with respect to intelligent creatures; which may be resolved into general laws or rules of administration, in the same way as many of the laws of nature respecting inanimate matter may be collected from experiment.*”

61. In speaking of natural law, we have hitherto adopted the definition given by Butler, but it is necessary to go a little more into detail, to explain the several senses in which ethical writers understand the term. Not only are different authors inconsistent with each other in the meaning which they attach to it, but scarcely one of them can be found who is throughout consistent with himself. Many of them appear to have had no very definite idea on the subject; and even those who set out by defining what they understand by the expression, “Natural Law,” yet afterwards employ it in such a manner as proves they have forgotten their own definition.

Law. Further explanation of the term natural.

62. A little attention will enable us to discover that the predominant idea which this term conveyed to the minds of the writers on this subject was one or other of the following:

63. 1st. The universality of the extension, and perpetuity of the continuance, of this law. Being a law imposed by the Deity upon the whole human race for their universal and perpetual observance, it is used in this sense in contradistinction to all those practical propositions of which the obligation is special or variable, and which might be ranked among natural laws, only that they want the qualities of universality and perpetuity. Thus the preservation of our health might be deemed a natural law; but not so the obligation to consult or follow the prescription of any particular physician, although there can be no doubt that the latter is morally binding.

2dly. The natural character of its sanctions; the rewards or punishments by which its observance is enforced; being such consequences as follow generally from human actions in the ordinary course of nature, without any miraculous interposition on the part of the Deity, or any systematic interference on the part of man. By systematic interference, we mean the interference of the human magistrate in execution of the sanctions imposed by a human legislator, in contradistinction to the casual interference of man, such as the pain which he inflicts on an offender who has provoked his resentment; this casual interference being ordinarily looked upon in the light of a natural sanction.

64. 3dly. The nature of its promulgation; where the law is such that it may be readily discovered by the ordinary exercise of reason and observation, in tracing the connection between human actions and their consequences. The word ordinary is here employed in contradistinction to any of the more subtle and far-fetched

* “Though we were to allow any confused undetermined sense, which people please to put upon the word *natural*, it would be a shortness of thought scarce creditable to imagine, that no system or course of things can be so, but only what we see at present. . . . But the only distinct meaning of that word is *stated, fixed, or settled*; since what is natural as much requires and presupposes an intelligent agent to render it so, i. e. to effect it continually, or at stated times, as what is supernatural or miraculous does to effect it for once.” *Analogy*, ch. i. sub fin.

† For example, such as the following. “Considering the Creator only as a being of infinite power, he was able unquestionably to have prescribed whatever laws he pleased to his creature, man, however unjust or severe. But as he is also a being of infinite wisdom, &c. 1 Blackstone's Commentaries, 40. “The Creator might certainly have formed all men at the same time, though separated from one another, by investing each of them with the proper and sufficient qualities for this kind of solitary life.” Burlamaqui, *Natural Law*, II. iv. 11. When we recollect the moral necessity of sociability, (No. 51.) and the provisions in nature for maintaining and strengthening it, even the momentary supposition of such a possibility as that hinted at by Burlamaqui, however subsequently explained, at once perplexes our reason, by the confusion

it makes between moral and human nature, and revolts our ideas of God's goodness and justice, by supposing he could do any thing so absurd and unjust. Burlamaqui, indeed, afterwards explains his meaning. But why suppose an absurdity for the sake of afterwards answering it? We quote the passage on account of the principle it involves. “These (the laws of nature) are not arbitrary laws, such as God might not have given, or have given others of a quite different nature. Supreme wisdom can no more than supreme power act any thing absurd and contradictory. It is the very nature of things that always serves for the rule of his determinations.” *Ibid.* II. v. 5.

* Butler, *Analogy*, Introd.

Law. deductions of reason. All men are not competent to carry out a long series of reasoning; many are not capable of understanding such a process when discovered and communicated to them by others. These more refined deductions of reason, therefore, because of their difficulty and consequent infrequency, are not considered to come within the meaning of the term natural, using that term in reference to the ordinary depth of men's understandings, and not to the abstract nature of things.

Uncertain limits of natural law.

65. It is scarcely necessary to observe, that when the signification of the term "natural law" is so unsteady, the limits of this law cannot be fixed, but will vary according to the particular sense which each individual jurist attaches to this term, and according to the particular notion he may entertain of the degree of generality, kind of consequence, or amount of intelligence and acuteness, which may, in his opinion, be requisite or sufficient to constitute *natural*.

66. Having premised thus much, in reference to the various significations of the term natural law, we will now proceed to consider the subject under the three following heads:—

1st. The proofs and sources of our knowledge of natural law.

2d. Its sanctions.

3d. Its rules and precepts.

Proof and sources of our knowledge of the law of nature.

67. I. The proofs and sources of our knowledge of natural law. On the source from whence the knowledge of natural law should be deduced, and the mode of proof by which it should be established, jurists have not agreed. Some rest their system on the foundation of revelation; some on the universal consent of mankind; whilst the generality of more modern jurists, since the time of Bishop Cumberland, reject these two foundations, and rest entirely upon that of reason, observation, and experience. We shall proceed to consider each of these three sources in order, premising that any system of morals which does not derive its supply from them all, must be incomplete.

Revelation.

68. 1st. With regard to revelation. A distinction has frequently been taken between the law of nature and revelation, to which we cannot assent. The law of nature does not prescribe one thing and revelation another. Revelation therefore is not a distinct code; it is only a peculiar expression of the natural or moral law, one or the other; in fact, it is not a substantive law in itself, but rather a distinct version of the moral law, impressed with the high authority of supernatural testimony. If we take the law of nature in its widest sense, as embracing the whole compass of morality, any system must be very incomplete which fails to include revelation among its sources. Whence but from revelation can we derive any knowledge of the great leading principles of morality? It is true the Deity has implanted in man a moral sense or faculty, and that moral sense suggests to some extent the precepts by which our conduct should be governed; but if we desire an acquaintance with the great and *perfect* moral scheme, we must look for it in the Scriptures, since there, and there alone, we find the great principles of eternal morality rising to their highest perfection, and the doctrine of universal love for the first time fully and clearly revealed as an established principle of action. It is true that among the speculations of the more enlightened heathens we find the love of mankind at large highly commended. Their mode of theorizing on the

subject is beautiful, but it never went beyond theory. In the Scripture it is, that the law of love is made the rule of life, and for the first time declared to be the only right and true law of human action.*

But although revelation be an indispensable foundation of a perfect moral system, yet it is not to be supposed that the moral code will be found there carried out into all its details, since, as has been well observed, "whoever expects to find in the Scriptures a specific direction for every moral doubt that arises, looks for more than he will find."† We must have recourse, in general, to other sources, for the details of duty.

69. 2dly. The consent of mankind. Grotius has used this mode of proof very extensively in establishing the law of nations. "I have likewise towards the proof of this law," he observes, "made use of the testimonies of philosophers, historians, poets, and, in the last place, orators; not as if they were to be implicitly believed; for it is usual with them to accommodate themselves to the prejudices of their sect, the nature of their subject, and the interest of their cause; but that when many men of different times and places unanimously affirm the same thing for truth, this ought to be ascribed to a general cause which, in the questions treated of by us, can be no other than either a just inference drawn from the principles of nature, or an universal consent."‡ Puffendorf rejects the consent of mankind as a proof of natural law;§ but it is evident that, in condemning Grotius, he has mistaken his meaning. The masterly defence of Grotius, by Sir J. Mackintosh, in answer to those who criticise his citation of authorities, is too good to be omitted:—"He was not of such a stupid and servile cast of mind as to quote the opinions of poets or orators, of historians and philosophers, as those of judges, from whose decision there was no appeal. He quotes them, as he tells us himself, as witnesses whose conspiring testimony, mightily strengthened and confirmed by their discordance on almost every other subject, is a conclusive proof of the unanimity of the whole human race on the great rules of duty and the fundamental principles of morals. On such matters, poets and orators are the most unexceptionable of all witnesses; for they address themselves to the general feelings and sympathies of mankind; they are neither warped by system, nor perverted by sophistry; they can attain none of their objects, they can neither please nor persuade, if they dwell on moral sentiments not in unison with those of their readers. No system of moral philosophy can surely disregard the general feelings of human nature and the according judgment of all ages and nations. But where are these feelings and that judgment recorded and preserved? In those very writings which Grotius is gravely blamed for having quoted. The usages and laws of nations, the events of history, the opinions of philosophers, the sentiments of orators and poets, as well as the observation of common life, are, in truth, the materials out of which the science of morality is formed; and those who neglect them are justly chargeable with a vain attempt to philosophize

* The mode in which the Mosaic law inculcates the universal law of love is beautifully exhibited by the late learned and pious H. J. Rose, in his *Notices of the Mosaic Law*, London, 1831.

Law.

Law. without regard to fact and experience, the sole foundation of all true philosophy.*

Observation, experience and reason.

70. 3dly. Observation, Experience, and Reason. As a source of our knowledge of natural law, revelation is not sufficient; its proper object, as we intimated above, is not the natural but the moral law. Neither is the consent of mankind alone sufficient, since this consent is not easily collected, and, even if it were, would still require the test of individual experience, to make our knowledge perfect. It is by examining nature, by observing human impulses and human actions, and their effects, in what general direction our instincts, prejudices, and passions point, and what are the external objects, in the attainment or avoidance of which the gratification of our physical appetites and preservation of our physical nature consist, that we perceive the primary indications of natural law. These general tendencies to action, when kept within due bounds by that sense of right which belongs to the moral nature of that complex being, man, constitute the system of natural laws. In tracing them out, it is not necessary to enter upon any profound metaphysical discussion; it is only requisite to observe the effects that follow from human actions, and to judge if those effects be universal. When we judge them to be so, it is impossible to attribute that universality to accident; we are irresistibly led to attribute that universal connection of our actions with their results, to an institution of Divine Providence, appointed for the purpose of indicating that law of our conduct to which they were calculated to lead us.

Sanctions of natural law.

71. II. We have next to consider the Sanctions of natural law. But in order to distinguish those sanctions from others to be presently noticed, to which they are nearly related, we must be careful not to confound man's moral with his human nature. As a moral being, man's perfection and complete happiness must ultimately depend upon his moral tastes and habits, and not upon his physical constitution. And it is essential to bear in mind that he was placed in the world for the purpose of exercising and improving, according to the opportunities afforded him, the several moral faculties with which he is endowed, but which as yet are imperfect and corrupted. Many writers, as, for example, Puffendorf and Burlamaqui, add considerably to the intrinsic difficulties of the subject, by regarding man, in the first instance, as a complex being, made up of soul and body, and then investigating the various provisions in nature, for satisfying his material concurrently with his moral wants; thereby unconsciously confounding together means and ends. The more proper, and, in our opinion, the only correct way of considering the subject, is the following. Granting man to be such an imperfect moral being as we have described above, how has God, by superadding the human nature which man now possesses, provided for his moral advancement? First, then, according to his human, and what we may regard as his purely adventitious constitution, man has many physical wants and requirements to be supplied and satisfied, and dangers to be avoided; and the supplying and satisfying of the former, and the avoiding of the latter, afford him an immediate object for active and strenuous exertion of a particular kind, and for the employment of all his faculties in a certain way. Thus a specific and definite form, or rule of action is marked

out for him, and not only marked out, but enforced through the instrumentality of those various wants and necessities to which his human nature is rendered subject. But in the mean time, while the outward man is thus acted upon, and by motives not of the highest kind, the moral man within is undergoing a salutary course of discipline, overcoming obstacles which stand in the way of his happiness, and gradually acquiring habits which will fit him for the purest enjoyments. The law of nature, then, regarded as a scheme of external compulsion, is subservient to moral discipline. Present or temporal good, which is promoted by observing the law of nature, is only incidental and subsidiary to the attainment of moral good, to the formation of habits, tastes, and dispositions, which are destined to have their full development and exercise in a future state of existence. Our attention must now be directed to the machinery by which the observance of the law of nature is enforced.

72. The sanctions of the law of nature consist in rewards as well as punishments; though, as already observed, (No. 38.) some writers have thought fit to make a gratuitous assumption that all sanctions consist exclusively of punishments. It does not appear under what category they would range rewards: that the latter certainly may and do form inducements, is apparent from the commonest observation of the ordinary course of nature, which not only allures to the performance of duty by the prospect of advantage, but deters from the commission of wrong by the dread of evil. The distinction after all is purely technical.*

73. Several of the most eminent and popular writers on the present subject, include among the sanctions of natural law, the moral happiness and misery which, considered as temporal consequences, result from our voluntary actions. They insist upon the intrinsic excellence of benevolence, justice, truth, and all the other moral virtues. They assert, what cannot indeed be disputed, that, even in the present life, the practice of virtue is attended with enjoyment of the highest and purest kind;† that putting aside all contingent and outward advantages, virtue is its own reward in the internal satisfaction, peace, and tranquillity of mind which it brings to its possessor; and this internal happiness they regard as the chief sanction of what they call the law of nature. As Cumberland states the proposition, all the virtues and that perfection of mind which accompanies them, are to be reckoned among the happy consequences or natural rewards of universal benevolence. Thus the practice leads to the growth of virtue; practical goodness becomes both means and end.‡ Vice is treated in a similar way. Its intrinsic evil is regarded as the chief discouragement to it.

74. Now this account of the matter is very beautiful, and in several respects perfectly true. And if the writers in question had confined their sanctions of natural law exclusively to moral good and evil, we could readily understand that by the law of nature they meant to express that which we have termed necessary law. But from the way in which they blend moral with physical

* See Puffendorf, *Law of Nature and Nations*, I. vi. 14. with Barbeyrac's notes; Burlam. *Nat. Law*, part i. ch. x. 11, 12; Cumberland, *Laws of Nature*, *Introd.* 14. ch. v. 40.

* Mackintosh, *Law of Nature and Nations*, p. 16.
VOL. II.

Law.

or material happiness and misery, from the co-ordinate rank which they assign to these two distinct species of good and evil,* considered in the light of sanctions, and from the indistinct mode in which they speak of the origin of these sanctions respectively, and of the final purpose of natural law, we are often left in some doubt as to their precise views or meaning. It is not very easy to discover, for example, whether their law of nature be a scheme of internal moral rectitude, or a rule of outward action; a law subsisting of itself, *i. e.* necessarily arising from the very nature of things,—or a positive institution of the Almighty; whether it be designed for man's ultimate moral perfection, or intended solely or chiefly to secure his present temporal welfare, morally as well as physically.† We have endeavoured, by the mode in which we have treated the subject, to avoid these sources of doubt and confusion.

75. Moral good and evil, then, must be regarded as the inevitable consequences of virtue and vice respectively. (No. 46.) They are not made the consequences of our voluntary actions, by an exercise of Almighty Power, in which respect they differ essentially from every species of good and evil depending purely on the physical constitution imparted to us by our Creator. Looking upon the law of nature therefore as a positive system, ordained by the will of God, we cannot properly consider moral good and evil as its sanctions, that is to say, as parts of the artificial machinery, by which God seeks to enforce the practice of virtue. An analogy in this instance holds with the municipal laws of a state. We are not at liberty to reckon among the sanctions of these, any consequences but those which the legislator himself may impose for the purpose of enforcing his will; though unquestionably obedience to the law is followed and may be further recommended by many ulterior advantages, which indeed suggested the reason for its institution. It was for the promotion of our moral good that the positive system of natural law was instituted by the Almighty. Moral good, however intrinsically excellent, however well calculated to recommend itself, without any adventitious inducements, to a mind duly prepared to appreciate it, demands a certain degree of moral proficiency in the agent before it can effectually influence him to any considerable degree. But such high proficiency is unattainable by man in the present life. Hence, then, the divine institution of the law of nature.

76. In another view, it will appear improper to class moral good and evil among natural sanctions. We can assign no bounds to the degrees or kinds of goodness and virtue to which a sincere desire of moral good would carry us, (for we may omit the dread of moral evil as belonging only to the lower degrees of virtue;) whereas the determinate, specific character of what are ordinarily regarded as natural obligations, and the distinction tacitly drawn between them and more imperfect obligations, show that they belong to a law whose

sanctions are applied to the enforcement of specific and limited rules.

77. Hitherto we have spoken of moral good and evil as they affect our happiness in the present world. For similar reasons to those above stated, the rewards and punishments of a future life should not be included among natural sanctions. Without any vain endeavour to pry into their precise nature, it is generally admitted that they are of a moral character, and that they are the necessary results of habits and dispositions acquired here. The soundest views commonly entertained of future happiness or misery, represent it as a continuation of that which is felt here, only greatly heightened. In the next place, future happiness is an end, and not a mean. It was with a view to it that the whole scheme of God's moral government was instituted; and it would therefore be incorrect to state, that future happiness and misery are imposed, in order to regulate our conduct here, as a final end or purpose. A future state of happiness or misery is disclosed to us by the Almighty as a distinct species of inducement: this disclosure partakes more of the nature of counsel than of law, the essence of which is enforcement. Lastly, the consideration of the happiness to be enjoyed in a future state of existence, like the desire of present moral good, is calculated to carry us much further than the mere observance of natural duties. These are our reasons for excluding future rewards and punishments from the category of natural sanctions. The hesitation of several moralists of the school of Cumberland and Puffendorf to admit these as sanctions, proceeds on a different ground; it is wholly connected with their peculiar acceptance of the word *natural*, which, according to them, includes whatever we are able to collect by the light of reason only without the aid of revelation; their recognition therefore of the sanctions here in question depends upon their opinion of the extent and power of our natural reason in arriving at the knowledge of a future state. Some of them, however, incline to the opinion that the system of nature must appear imperfect, unless we suppose a future life. The distinction indeed between natural and revealed law is very generally recognized; still we cannot help thinking that the ordinary method of explaining the subject does not sufficiently show the full force of the word *law*, in the phrase, law of nature.

78. The moral obligation of obeying God's will is wholly independent of natural law, as we understand it; that is, independent of those additional sanctions to which we now come, and by which He urges us to the outward practice of virtue. Motives of the highest self-interest—the consideration that practical discipline systematically enforced must be submitted to, in order to the acquisition of habits essential to our final happiness—ought in reason to have sufficient weight to induce us to observe any system of practical rules proposed to us by Infinite Wisdom, even if the rules of practice marked out for us were simply declared, without being enforced. But God's natural, which is subservient to his moral, government of mankind goes further than simple declarations; it consists, as Bishop Butler observes, in God's annexing pleasure to some actions, and pain to others, and giving us an opportunity of knowing beforehand that such consequences will follow. In our mode of treating the subject, we are obliged to restrict those consequences within narrower limits than Butler seems to have contemplated; we

Law.

Nor are the rewards and punishments of future life.

* See Paley's *Moral Phil.* book i. c. 6.

† Leibnitz, in a little tract, entitled *Monita quædam ad Samuelis Puffendorfi Principia*, charges the author whom he criticises, with the commission of three fundamental errors. First, with confining the science of natural law and its ultimate aim, within the limits of the present life; as if it were possible to afford a complete and correct view of the whole subject, without embracing the consideration of man's final destiny. Secondly, with paying too exclusive a regard to outward actions, as opposed to inward principles. Thirdly, with making all duty, right, and obligation to depend on the arbitrary will of a lawgiver.

Law. confine them to physical or purely material advantages. These constitute the artificial, positive, or compulsory part of the Divine scheme of government; and they consist in those external consequences which follow our outward actions, in the common course of nature.

Sanctions of natural law are of an external and temporal nature. 79. Under this view, these various sanctions of the natural law may briefly be asserted to consist in all the external consequences which restrain or impel human conduct; any temporal advantages or disadvantages, which, operating upon human instincts, passions, prejudices, reason, or forethought, induce mankind in general either to acts or forbearances; all those benefits which may be summed up under the general name of utility. The great difficulty and abstruse nature of this comprehensive topic must forbid an enlargement upon it in a treatise of this kind: more especially as the complex constitution of man's nature has blended together motives essentially different in themselves, and has induced jurists and moralists to confound them in their statements and definitions.

Reason not a sufficient guide, from man's imperfection. 80. It is a trite observation that, in order to follow the law of nature, "right reason" is to be our guide. It is unquestionable that by reason is exhibited the standard of what is right: but it does not express the successive steps by which we are led to that exalted height. Were man a perfect being, reason, under which we would include all higher moral motives, would be sufficient, since he would require no inducements: but the very existence of moral and physical pain and pleasure are not only inducements in themselves, but evidences that he stands in need of them. In fact, there is a mutual connection and dependence between reason and those subordinate matters which form the sanctions of natural law. Reason will instruct the instinct, correct the passions, soften, without eradicating the prejudices, and direct our views to more distant objects: while, on the other hand, all these call our dormant energies into action, when the reason would be too slow of itself to incite us.

81. "We can easily imagine," observes Sir James Mackintosh, "a percipient and thinking being without a capacity of receiving pleasure or pain. Such a being might perceive what we do: if we could conceive him to reason, he might reason justly; and if he were to judge at all, there seems no reason why he should not judge truly. But what could induce such a being to *will* or to *act*? It seems evident that his existence could only be a state of passive contemplation. Reason, as reason, can never be a motive to action. It is only when we superadd to such a being sensibility, or the capacity of emotion or sentiment, (or what in corporeal cases is called sensation,) of desire or aversion, that we introduce him into the world of action. We then clearly discern, that when the conclusion of a process of reasoning presents to his mind an object of desire, or the means of obtaining it, a motive of action begins to operate; and reason may then, but not till then, have a powerful though indirect influence on conduct. . . . The general tendency of right conduct to permanent well being is indeed one of the most evident of all truths. But the success of persuasives or dissuasives addressed to it, must always be directly proportioned, not to the clearness with which the truth is discerned, but to the strength of the principle addressed, in the mind of the individual; and to the degree in which he is accustomed to keep an eye upon its dictates. . . . It is apparent that the influence of reason on the will

is indirect, and arises only from its being one of the channels by which the objects of desire or aversion are brought near to these springs of voluntary action."*

82. That state of perfection which we have already intimated (No. 52.) should form the ultimate aim of every reasonable being, is such a condition of moral taste and disposition, as pursues *spontaneously* what is good. It is the spontaneous quality of that disposition which we now wish to point out. Religion and morality both concur in representing the most excellent state to be, without a figure, a state of perfect freedom. But how is man to be brought to such a condition, that every principle of good may be in full activity, without any tendency to deflect towards evil, and all this without any external coercion? The gracious arrangement of Providence is this: first, to impel him, almost mechanically, by means of those sanctions which take their rise in his instinct and passions: then, to influence him less coercively by motives still of a temporal nature, but more distant, more the objects of forethought and reason, and therefore more consistent with free-agency; and, by gradually withdrawing the objects of sense, in proportion as the distant and the future predominate over the present, to train him for the contemplation of things still more remote and exalted. We may observe, that in the course of nature the greater is made the more distant good. It is evident that in this last condition, he is a more spontaneous agent than when under the influence of the immediate and urgent pressure of the lower kind of natural inducements.

83. The attainment of this spontaneous condition is further promoted by the occasional uncertainty in the event of distant natural consequences. Were the results of our exertions undeviatingly successful, we should become the mere slaves of sensible objects. Whereas, by the present constitution of nature, the general event of our voluntary actions is just sufficiently certain to direct us in the right course, but is sufficiently uncertain to prevent the object originally in view from being the ultimate end of our pursuit. Further, by this occasional disappointment and uncertainty, the limits between spontaneous and coerced action is left somewhat indefinite; a circumstance evidently favourable to a gradual transition of the agent from the trammels of natural law to a state of moral freedom.

84. It thus appears, that the sanctions of the law of nature must be regarded only as helps to the sanctions of the moral law, that is to say, as additional and inferior inducements to the observance of that inward practice, which the moral law requires as an inward principle.

85. The sanctions or natural consequences which we have been discussing are universal, and therefore it must be that the law to which they are referable must be universal in its operation, being coextensive with the human race, and with the system of this world: having been instituted at the creation by the Divine Legislator himself, and sustained ever since by his perpetual ordinance. We do not of course here mean some of those consequences, which though on other grounds they might be called natural, yet, wanting the property of universality, cannot properly be considered as parts of the natural Law. Natural consequences are also perpetual or constant in their operation. "We may say, perpetual,

* Sir James Mackintosh, *Dissert. on Progress of Ethical Philosophy*, sec. 5.—p. 152—154.

Law. if we will, that the laws of nature are eternal: though, to tell the truth, this expression is very incorrect in itself, and more adapted to throw obscurity than clearness upon our ideas. Those who first took notice of the eternity of the laws of nature did it, very probably, out of opposition to the novelty and frequent mutations of civil laws. They meant only, that the law of nature is antecedent, for example, to the laws of Moses, of Solon, or of any other legislator, in that it is coeval with mankind; and so far they were in the right. But to affirm, as a great many divines and moralists have done, that the law of nature is coeternal with God, is advancing a proposition, which, reduced to its just value, is not exactly true; by reason that the law of nature being made for man, its actual existence supposeth that of mankind. But if we are only to understand hereby, that God had the ideas thereof from all eternity, then we attribute nothing to the laws of nature but what is equally common to everything that exists." *

and
generally
known.

86. The last thing to be observed with regard to these sanctions of natural law or natural consequences, is, that they are generally known: they are recognized and assented to by our instincts, our senses, our reason, and our experience; in short, they are universally promulgated, and written upon the heart of all mankind by Him who devised and framed them.

Rules and
precepts of
natural
law.

87. III. We now come to consider the rules and precepts of natural law. Being a positive law it is specific in its character. Though doubtless containing principles, yet these are of a less abstract character than those which belong to the moral law. This conclusion must naturally follow from what has just been said with respect to its sanction. As the moral law is too distant and elevated in its nature to be sufficient for inciting man, in his present state of weakness, without the intervention of these more proximate inducements which the law of nature affords, so is it too wide and expanded to guide his narrow and shortsighted will and judgment, without the interposition of certain landmarks, which may confine his steps within determinate bounds. The specific nature of these rules may best be shown by a few examples. To select, then, one among the most obvious and important of our instincts, namely, love. If this primary affection of our nature were, on the one hand, to indulge in a too extensive range of objects, it might be dissipated away, or, on the other hand, were it without immediate objects, it might perish for want of exercise: whereas, by the present constitution of nature, it is capable of being gradually refined into the highest and noblest affection, and indefinitely extended without danger of attenuation. Hence it is that love, in order to its ultimate purer and more perfect exercise hereafter, is here, under the influence of the law of nature, determined by the specific rules of domestic affections. And here it is observable, that the strongest affections are those which, in their legitimate exercise, are confined within the narrowest limits: the filial, or paternal, or conjugal affection for instance, is stronger than that which regards the domestic circle in general; the domestic affections are more powerful than the love of country; which, again, is more powerful than universal philanthropy. And it is further to be remarked, that the more confined and powerful the affection is, in the

Their
specific
character
exempli-
fied.

Law. same degree it the more nearly partakes of the character of animal instinct. To use the words of Hume, "This partiality, then, and unequal affection, must not only have an influence on our behaviour and conduct in society, but even on our ideas of vice and virtue; so as to make us regard any remarkable transgression of such a degree of partiality, either by too great an enlargement or contraction of the affections, as vicious and immoral. This we may observe in our common judgments concerning actions, when we blame a person who either centres all his affections in his family, or is so regardless of them, as, in any opposition of interest, to give the preference to a stranger or mere chance acquaintance." * The same considerations will obviously apply to other instinctive predilections: but it is not necessary to specify them here in detail. It may be sufficient to observe, that it is only by attending to the ultimate purpose to which they contribute so effectually, and for which unquestionably they were designed, that we are enabled to reason about them at all, or to view them otherwise than as so many unmeaning weaknesses, unworthy of rational creatures, and which ought therefore to be got rid of as speedily as possible. This indeed can seldom be the case with the social predilections above noticed. Their temporal, if not their moral utility is so obvious, even to shallow observers, that their propriety is seldom brought into question. Though even with regard to them, the world has occasionally afforded specimens, happily rare, of *philosophers*, who have betrayed a ridiculous ignorance of human nature and its requirements and an incapacity of taking a combined view of ends and means, by seriously advocating an universal philanthropy of the most impartial kind, at the expense of our more confined and therefore warmer affections; utterly forgetful that a pure, abstract, perfect justice, which bestows its regards strictly in proportion to the merits of its objects, can only be approached, by such a being as man, gradually and through the medium of that wisely adjusted scale of natural affections, which, though symptomatic of imperfection, and implanted in us because of such imperfection, constitutes nevertheless an essential element in human or *natural justice*.† The order of nature prescribes not that our primary and deeper and more partial affections should be depressed to the lower level of our more distant and extended, though more impartial regards, but that the latter should be gradually elevated to the higher level of the former.‡ So far

* Hume, *Philosoph. Works*, vol. ii. p. 258.

† "Eademque ratio fecit hominem hominum appetentem, cumque his naturâ, et sermone, et usu congruentem; ut profectus a caritate domesticorum ac suorum, serpat longius, et se implicet, primum civium, deinde omnium mortalium societate; atque, ut ad Archytam scripsit Plato, non sibi se soli natum meminerit, sed patriæ, sed suis, ut per exigua pars ipsi relinquatur." Cic. *De fin.* ii. 14.

"In omni autem honesto, de quo loquimur, nihil est tam illustre, nec quod latius pateat, quam conjunctio inter homines, et quasi quædam societas et communicatio utilitatum, et ipsa caritas generis humani; quæ nata a primo satu, quo a procreatoribus nati diliguntur, et tota domus conjugio et stirpe conjungitur, serpit sensim foras, cognationibus primum, tum affinitatibus, deinde amicitis, post vicinibus; tum civibus, et iis qui publice socii atque amici sunt: deinde totius complexu gentis humanæ: quæ animi affectio, suum cuique tribuens, atque hanc, quam dico, societatem conjunctionis humanæ munificet et æque tuens, justitia dicitur: cui adjunctæ sunt pietas, bonitas, liberalitas, benignitas, comitas, quæque sunt generis ejusdem." *De fin.* v. 23.

‡ It may be remarked that such passages as *St. Matth.* vi. 46, 47; *xxii.* 39; &c., do not depreciate the lower standard of

Law. with regard to our social predilections: their value and obligation depend altogether, it is generally admitted, on their ultimate moral effects. The same principle must hold good with regard to all other instincts and prejudices of universal occurrence, however unmeaning they may appear at first sight: they also must be judged of, not abstractedly, but by reference to the ends they produce. And it will be found, that several of the most valuable human institutions, property and government, for example, respecting which so many theories have been set afloat, depend, for their stability, on some divinely appointed and useful prejudice.

88. To give one other example: it was necessary that the principle of activity should be developed and exercised in man. But in this respect, he is not simply furnished with the principle, and left to discover for himself modes of exercising it. The necessity of providing for his physical wants directs his energies into certain determinate channels, in which they are nursed and matured. It is the law of nature that gives them that particular direction for purposes of discipline; it remains for morality to point them to higher and better objects.

Division of the laws of Nature. 89. But it is time to consider, in their proper order, the rules themselves of the law of nature. They may be divided, with reference to their immediate objects, into our obligations towards God, towards ourselves, and towards other men. We shall consider them under these heads with the utmost possible brevity.

Duties towards God. 90. To begin with our natural duties towards God. They include both speculative belief and practical observances. First, as to speculative belief, which must necessarily precede all external acts and duties of religion. The notion of a Deity is one which has been generally entertained, at all times, and in all countries, with the exception of a few of the most barbarous. It has been held, says Grotius, as well by those whose understandings were too gross to impose on others, as by those who were too wise to be imposed on themselves. Grotius attributes, with much apparent probability, this general persuasion to an universal tradition derived from the early patriarchs; for though, he observes, God's existence may be satisfactorily demonstrated by reasons and arguments drawn from nature, it is not every one that is capable of understanding the proof. In general, men are prejudiced in favour of their religion before, if ever, they reason about it. The ideas entertained of a Divinity are, in many cases, very imperfect and distorted; but there are two points essential to every religion, true or false, upon which the great majority of mankind are agreed, namely, the existence and the moral government of God. The notion of a divine providence is one which finds something congenial to it in the human mind, and it derives great strength from the authority which the mere fact of its general reception is calculated to convey. For these reasons it is a truth upon which jurists affirm no difference of opinion can be tolerated. We mean the doctrine of a moral Governor, for a perfect knowledge is not contended for.

Practical. 91. The practical part of natural religion includes worship, consisting in acts of prayer, thanksgiving, and adoration; and reverence, consisting chiefly in forbear-

our more common or natural affections; they only exhibit a still higher one to be aimed at. The sentiment in *St. Matt. xii. 50*, could not, with propriety, have been uttered by an ordinary man.

Law. ance from open disrespect.* It is natural, because man's natural constitution, by an impulse or instinct, leads him to manifest sentiments of respect, towards whomever entertained, in outward expressions and significant actions. Accordingly, some form of worship or other has always obtained in every place where a Deity has been acknowledged. What applies to worship will apply still more strongly to the negative duties of reverence, which can scarcely be withheld consistently with a true belief in a Supreme Governor of the world.

92. The outward part of religion is connected with the inward, both as *cause* and *effect*. Worship springs from inward reverence, and also contributes to it. It is from considering outward worship in the latter aspect, that we derive its moral obligation (No. 38.); because, by increasing our reverence towards, and therefore our love of, God, it promotes our highest happiness.

93. We next come to our natural duties towards ourselves, which may be disposed of in a summary way. They consist, according to Puffendorf, in duties of self-perfection and self-preservation. But the duties of self-perfection treated of by him have properly no place in a treatise on jurisprudence. The natural duties of self-preservation include all that relates to the preservation and integrity of our life and body, and consequently enjoins all the acts necessary towards their sustentation. They forbid self-destruction, and self-abuse of every kind. The natural sanctions by which these become laws of nature, after what has been said respecting natural sanctions, must be too evident to require any observation.

94. Our social or relative obligations form the third and largest class of natural precepts. We shall consider the several relations men stand in towards each other, first, in their personal capacities; secondly, in relation to things. To these a third division is sometimes added by modern writers, especially those of Germany; namely, the natural law of facts. Some censure the addition of this third division, as unphilosophical.

95. Were we to examine at length the various duties and rights incidental to the general relation in which all men stand towards each other, *as men*, it would lead to too long a discussion, and would be inconsistent with the plan we have adopted. Certain rights are represented as naturally belonging to every man, who has not forfeited them by his misconduct. They are principally four: viz. 1. a right to his life and the safety of his person; 2. a right to acquire property; 3. a right to his reputation; 4. a right to liberty. These are rights which every one will be disposed to claim, and which every right feeling man conceives himself under an obligation of conceding to others. It is evident that natural inducements will not be wanting to assert them. But some of them, the fourth especially, are somewhat indefinite; and under this general head, it will not be desirable to attempt a discussion of their exact limit. We shall therefore proceed with the particular relations of persons. "Almost all the relative duties of human life," observes a writer frequently before quoted, "will be found more immediately, or more remotely, to arise out of the two great institutions of property and marriage. They constitute, preserve, and improve society. Upon their gradual improvement depends the progressive civilization of mankind; on them rests the whole order of civil life. * * * These two great insti-

* Paley, *Mor. and Pol. Phil.*, book v. ch. 1.

Law.

tutions convert the selfish as well as the social passions of our nature into the firmest bands of a peaceable and orderly intercourse; they change the sources of discord into principles of quiet; they discipline the most ungovernable, they refine the grossest, and they exalt the most sordid propensities; so that they become the perpetual fountains of all that strengthens, and preserves and adorns society; they sustain the individual, and they perpetuate the race. Around these institutions all our social duties will be found at various distances to range themselves; some more near, obviously essential to the good order of human life; others more remote, and of which the necessity is not at first view so apparent; and some so distant, that their importance has been sometimes doubted, though, upon more mature consideration, they will be found to be outposts and advanced guards of these fundamental principles; that man should securely enjoy the fruits of his labour, and that the society of the sexes should be so wisely ordered as to make it a school of the kind affections, and a fit nursery for the commonwealth."*

Relation of husband and wife.

96. The liberty which has been just described as one of the rights naturally incidental to every person, includes the right of contracting marriage; from whence spring the two *private* natural relations of husband and wife, and parent and child. And first, of husband and wife.

97. The sexual appetite implanted in all animals serves to perpetuate their species, but in man becomes the instrument of still higher purposes, through the natural institution of marriage. If we look merely to the propagation of the species, or the general good of society, we get a very imperfect view of the importance and obligation of marriage. To estimate these fully, we should consider its lasting moral effects on the parties themselves; how their natural passion of love, by being permanently confined within strict limits, is refined as well as deepened, and gradually deprived of its selfish character by its extension to new objects, viz.—the offspring of their union.

The marriage contract.

98. The mutual consent of both parties is essential to establish the relation of husband and wife. But on the subject of the *natural* mode of signifying this consent, jurists seem to have forgotten that here, as confessedly on other subjects, *natural* admits of comparative degrees; whereas they assert that the lowest, that is, the least formal manner of signifying consent, which is only just sufficient to bind the parties, is the *natural* mode. Undoubtedly, where no particular form of compact is established by law, or prevails by custom, any mode, which in the eyes of the parties themselves amounts to such a compact, will be naturally sufficient to bind them. But there is, on the part of mankind, a disposition, if not universal, at least very common, to invest with importance the entrance into the state of marriage, by accompanying it with ceremonies, often of a religious cast. Men are also naturally disposed to observe engagements contracted with circumstances of solemnity, and above all of religious solemnity, with more scrupulous fidelity than any others. We state facts without attempting to account for them. It might therefore be fairly argued, both on the ground of general disposition and of reasonableness, that a solemn religious mode of contracting marriage is the *most* natural. The disclaimer, on the part of many jurists, of such epithets as *holy* or *sacred*, as applied to marriage

in its civil relations, is absolutely puerile. By whom ever the *state* of marriage (not the mere mode of entrance into it) is viewed, the importance of availing ourselves of all means to maintain its obligations inviolate, can scarcely be over-estimated.

99. It will be evident that the *moral* purposes of marriage above slightly traced out, involve two essential conditions, exclusiveness and permanence, and are best answered by making those conditions as strict as possible. Hence it appears that monogamy, terminating only with the life of one of the parties, is the most perfect form of conjugal union. Monogamy has therefore been established in all Christian communities, as Grotius expresses it, in order that the wife, bestowing herself entirely on the husband, may receive the equal return of his whole heart and affection. The equality of the sexes, and the general practice of mankind, point this out as the *most* natural form. Puffendorf remarks that, where a man has several wives, he usually singles out one as a favourite.* Polygamy has however been practised in many nations both ancient and modern, without disapprobation by the wise and good; and all the ends of marriage may be answered, consistently with it, though less perfectly than by monogamy. For these reasons it has been held that the law of nature does not absolutely forbid it, though it ought not to be tolerated in a Christian community. Observations not very dissimilar will apply to the power of terminating the matrimonial relation before its regular conclusion, by divorce. The law of nature at all times prescribes, as its *most perfect rule*, the indissoluble maintenance of the matrimonial relation during the joint lives of the parties, except in the single case of adultery; a rule generally followed, though with exceptions. Here it coincides with the only rule permitted by Christianity; but the law of nature tolerates an inferior rule of morality; as we find in the comparative facility of divorce indulged to the Jews, for example, and not condemned, even followed, by confessedly good men.

100. There is but one more topic connected with marriage, to be touched upon here; namely, respecting the degrees of prohibition, according to the law of nature, on account of affinity and consanguinity. Three classes of the natural degrees of prohibition are noticed by jurists: first between parents and children, and more remote descendants; these have been justly held in universal and unqualified detestation at all times and in all countries. Secondly, between brothers and sisters; which, though strongly condemned in general, as contrary to the law of nature, have been so in a somewhat modified degree. Thirdly, between more remote collaterals; about which there has been not only some variety of practice in different ages and countries, but some variety of opinion among jurists. Writers have attempted in several ways to account for such prohibitions; but our space will not allow us to follow their theories. Grotius alleges the question to be most nice and difficult, and that whoever attempts to assign cer-

* *Law of N. and N.*, VI. i. 19. On the subject of marriage, Puffendorf, though learned and methodical, is anything but profound. He takes a low view of its purposes, and argues upon the subject too much like a lawyer. He not only mistakes in some instances the *invariable terms* of the conjugal union, but he carries the initial compact with him throughout the whole matrimonial status, instead of treating it merely as the barrier which gave entrance, but prevents egress.

* Mackintosh, *Disc. on the Study of the Law of N. and N.*, 35.

Law. tain and natural rules why marriages in such cases are unwarrantable, in the manner they are prohibited by the laws and customs of nations, will find by experience that the task is both difficult and impracticable.* May we hazard the conjecture that the God of nature implanted these natural aversions, along with the physical defects incidental to unions of the kind here supposed, in order to induce mankind to extend their alliances beyond their own families, and thereby cultivate a more comprehensive social affection?

Parent and child.

101. On the relation of parent and child, little need be said. The right of parental authority is commonly stated by jurists to be founded in generation;† but this only indicates the person, not the foundation of the right. How, indeed, can the mere fact of having been the instrument of a child's earthly existence, abstractedly confer any authority of the kind? Puffendorf builds the right partly on a supposed tacit compact,—he loves compacts,—balancing the right of parental government against the duty of support! But the only true ground of natural parental authority is natural parental affection, for it secures the probability of good parental government. (No. 55.) The want of it therefore will go far towards depriving the parent of that right, on the principle of law, that *cessante ratione, cessat etiam lex*; but it must be a very gross case indeed, which will, in point of natural justice, warrant a compulsory legal interference with parental rule. On principle, we must be careful how we follow the dangerous example, set by some writers, of proposing for rules of exception extreme cases of very rare occurrence. It is to be lamented that both Puffendorf and Grotius should have committed an unwise mistake of the kind, by formally propounding it as a general rule, that parents, if unable to support their children, may, by the law of nature, pawn or sell them.‡ Silence, upon such a distressing case of extreme necessity, would surely have been preferable. The question, to which of the parents the right of government over the children exclusively or principally belongs, has occasioned some discussion and difference of opinion among jurists: some give it to the father on account of the greater dignity of the male sex; some to both parents equally. The latter probably comes nearer the truth; but as the age and sex of the child, and the disposition of it and its parents respectively, will point out, in the best possible way, how, when, and by whom the authority on each occasion ought to be exercised, it is surely idle to speculate further upon the point. At the proper age, nature will indicate, by the feeling of and qualifications for independence on the child's part, that the strict exercise of parental authority ought to cease. But, of course, no abrupt line, in this, or perhaps in any instance, offers itself in nature.

Law of Things.

102. The order of our subject now brings us to the natural law of things. The first point to be established is the right of the human species, exclusive of other

beings, to the free use of and dominion over the inferior creation, both animate and inanimate. The attempts of philosophers hitherto to render a rational account of this right, are far from affording complete satisfaction; indeed their arguments are often extremely fanciful. It seems best, therefore, to rest it altogether upon authority; upon the general practice and sentiments of mankind, and still more upon the indisputable authority of Scripture, which expressly declares the Creator's will in this respect.* The texts, however, here referred to, establish nothing more than the right of the human species generally; they give no intimation of the mode in which it was intended that mankind should avail themselves of the divine permission to take and use the objects designed for their support; they are silent respecting the relative and conflicting claims of individuals; they do not, for example, determine whether, or how far, a particular person, in taking what he requires, is at liberty to consult, exclusively or chiefly, his own convenience, or is bound to pay regard to the wants of others. In the actual distribution of worldly substances which has, somehow or other, been effected, one of the most striking phenomena, and that which at first sight appears most repugnant to our preconceived notions of abstract justice, is the gross inequality that everywhere prevails. It might be argued, that all having equal need of support, and none being expressly excluded in the terms of the original gift to man, every one might fairly lay claim to an equal share. Yet not only is the contrary system rigorously maintained by law, but jurists are all agreed at least upon one point, namely, in their determination to support it by reason, though the diversity of their arguments shows that the several reasons alleged by them are neither so complete nor so satisfactory in all cases as might be desired.

Law. The general right of mankind to things.

103. Exclusiveness and permanence are the chief essential characteristics of a private dominion over things, or property. By exclusiveness it is implied that the proprietor has or claims the sole right of using or directing the use of some particular object; by permanence, that he has that sole right, not to serve a temporary occasion only, but for an indefinite period to come; or, as it is expressed, he has a right to the very *substance* of the thing to be used. The inequality above noticed is perhaps an accident of property; but it is an accident which, as we have intimated, universally accompanies its establishment, and it is the circumstance which has occasioned the chief difficulty attending the examination of the subject. Opposed to the system of permanent distribution implied by private property, stands what is called the "original community of things." The term *original* points to the real or supposed state of things at some early period of the world, not exactly defined. The term *community* is equivocal. Sometimes it implies that condition of unheeded neglect in which objects of possible utility continue, before any one appears to use or appropriate them. In this sense all things were at one time common, and some continue so to the present day. Writers who aim at a superior degree of exactness distinguish this species of community by the epithet *negative*. The other, or *positive community*, implies that the objects said to be common have indeed been permanently converted to the use of man, but not made the property of any one or more individuals exclusively of all others; but that every one, without dis-

The nature of private property.

Its inequality.

Original community of things, regarded as an historical fact.

* *De J. B. et P. II. v. 12.* The whole of what Grotius says on the subject of marriage in this chapter is well worthy of careful perusal. Upon this, as upon most topics, this great jurist shows himself vastly superior to Puffendorf.

† *Puff. Law of N. and N. VI. ii. 4. Grot. De J. B. et P. II. v. 1.*

‡ *Puff. VI. ii. 9. Grot. II. v. 5.* Grotius, in support of his position, refers to the Mosaic law. The passages he cites (*Exod. xxi. 7.* and *Deut. xv. 12.*) prove the previous existence of the practice; but the law of Moses at most but tolerates it, and interposes expressly for the purpose of securing good treatment to the objects of sale.

Law.

pute or contest, uses the objects as he has occasion, from time to time, leaving them, (if not of a perishable nature,) when the occasion ceases, to be used in like manner by any one else. There is an essential difference, it may be observed, between these two species of community. In the former, there is no *property* in any sense, no severance from the general stock. In the latter, there is a severance: the dominion of mankind is asserted over the objects positively common; the human species collectively is the proprietor, and the brute creatures are the excluded parties. But the property, or permanent and exclusive dominion, extends no further; it does not obtain between man and man. Now this latter state is the condition represented in the fables of poets concerning the golden age; and it is gravely asserted, without much thought, by some jurists, to have been the primitive state of things in the first ages of the world. Blackstone, for example, in his elegant and much admired sketch of the rise and progress of property,* (by the way, chiefly borrowed from Grotius,) treats it as a positive fact. But is this at all likely to have ever been the case? (we can scarcely suppose that the dreams of poets would have been adopted as a mere embellishment, wholly unsuited as they are to the severity becoming a philosophical inquiry after truth;) or rather, is the assumed fact consistent with the nature of man, which has been the same ever since the fall, for with man before his fall we have no concern? What are the circumstances universally attendant on human nature, which, by an inevitable consequence, lead to the establishment of private property? Externally, there are man's wants, and the indispensable necessity of labour for supplying them; internally, there are his natural selfishness and love of ease. Be it that, in the early ages of the world, before arts or luxury had made much progress,† his wants were few; still it required no inconsiderable share of labour, even under favourable circumstances of climate, &c., to supply those few wants; and, taking him in the average, his love of labour and of his species was never so strong as to induce him to forego the fruits of his labour, either from an indifference to the necessity of repeating it, or from a disinterested generosity towards others. In proportion to the trouble expended in acquiring possession of some useful object, or in preparing it for use, would be the tenacity with which he would hold, and the vigilance with which he would guard it, in other words, his assertion of a private and exclusive dominion over it. His natural selfishness and love of ease would be aided further by an instinctive persuasion, or prejudice, that he had a right to keep to himself whatever he found unoccupied, and chose to improve by his own labour and skill. Labour, then, taken in connection with the natural wants and feelings of man, is a chief and primitive cause of private property. A further

The natural rise of property.

* *Commentaries*, vol. ii. p. 2, &c.

† Jurists sometimes favour us with a sketch of the supposed order in which the principal arts came into operation, as they naturally tend to promote private property, by suggesting new uses of things, and new modes of labour. Agriculture is supposed to have been of comparatively late growth; but, it has been observed, the first-born man was a tiller of the ground. It is therefore highly probable that he asserted a private dominion in the soil, at least during the interval between preparing the ground and reaping the crop. We may add, that it would not be consistent with his character to suppose him capable of exercising that forbearance which a community of property must constantly demand.

cause, but one, for the most part, of later growth, is the scarcity of useful objects; human selfishness will naturally induce a man to grasp at what but few can obtain. This cause, we say, is, *for the most part*, of later growth; for though, with regard to most objects of utility, a scarcity is not experienced till the increase of population has increased the demand, whilst the supply remains stationary or even declines, still some things are by nature originally and absolutely scarce. We conclude then that private property was the order of the world from the commencement, though less regular and systematic, and embracing fewer objects, compared with the number of inhabitants, than in later times. Hitherto, however, we have spoken of separate property as a fact, apart from its equity or justice; for whether our view of the early state of things be correct, or whether, as those who depict mankind as originally holding all things in common would have us believe, the system of private property be a departure, gradually introduced, from the mode observed in primitive times, no historical delineation, however true, of the perpetual and universal triumph of a seemingly selfish, monopolizing spirit over a disinterested or at least equal regard for the wants and requirements of all, can amount to a complete proof of the rightfulness of the system which accords in perpetuity to individuals whatever they or their ancestors, finding without an owner, have succeeded in laying their hands upon. From the question of fact, then, we shall now turn our attention to the question of right.

104. Neither our limits, nor our plan, which is to exhibit principles rather than opinions, will permit us to follow the several schools of jurists through their more minute shades of difference.* Almost all the accounts given of the origin of the *right* of property will be found, under various modifications, to be connected with one or other view of the "original community of things," expressive, not, as heretofore, of an historical fact, but of a doctrine of primitive right. Jurists in general may, upon this point, be distributed into two great sects,—those who hold respectively the doctrine of a positive and of a negative community of things. The positive community asserts that each man has an original right to an equal distributive share of the surface and productions of the earth, of which, whatever distribution may have been made provisionally or by usurpation, he cannot be justly deprived without some act naturally (that is, according to acknowledged principles of universal justice) calculated to have that effect. We state the doctrine without exaggeration, though somewhat more explicitly than its favourers in general venture to do. How then do they endeavour to reconcile, or rather to force an agreement between their notions of primitive justice and the claims of existing proprietors? By the convenient fiction of a tacit compact,—the ready refuge of a certain class of jurists on all occasions of difficulty,—whereby every one is supposed, at some period or other, to have voluntarily surrendered whatever original claim he had to a distributive share of the material objects of property, and to have confirmed the defective titles of the actual holders. This theory, however, will not bear the test of examination. Senseless as a

Law.

fiction, groundless as a fact, even if we could attribute to this airy phantom some substance of reality, it labours under every species of incurable vice, and leaves unexplained difficulties at least as great as that which it is intended to solve.* It may indeed be said that the allegation of a tacit compact is only a mode of expressing the general approval of the institution of property in all ages and countries, evidenced by its general adoption. But this explanation only nullifies the intended solution. It substitutes authority for reason. It asserts, in substance, that mankind in general feel and act one way, whilst right and justice are in the opposite direction. If there be any truth in the assumption that all men have or had originally the right that is pretended, then the general acquiescence of mankind is an acquiescence in general injustice, until some substantial *bona fide* transaction, superseding that right, be *proved*, not feigned. Again, it is a misrepresentation and abuse of terms, to ascribe in any degree to such an acquiescence the character of a compact. If the matter acquiesced in be naturally right, the giving or the withholding of the consent of men does not constitute or impair its rightfulness. There is, however, some foundation of truth in the doctrine of equality; but its extent and the mode of its assertion are misunderstood by those who make use of the fiction of a tacit compact. We shall have to consider this point presently.†

Doctrine of
a negative
commu-
nity.

105. The doctrine of a negative community asserts, that things, originally, that is, prior to any actual use or occupation of them, instead of being the property of all equally, are the property of none. Things being common in this sense, it is held that whoever first reduces them into his own possession, in order to prepare them by labour for use, thereby makes them his own. Some consider that it is the fact of occupancy alone, others that it is the labour which he adds to them, that gives him his title: it will be unnecessary at present to discuss which is the sounder view, or whether there is any substantial difference between them. Locke is commonly regarded as one of the ablest and most successful supporters of the doctrine of a negative community, and of the consequent title by labour, and his views upon the subject of property do not substantially differ from those of most other supporters of the same doctrine.

Locke.

His theory
of labour.

We shall give the pith of his argument in his own words. "Though the earth and all inferior creatures be common to all men, yet every man has a property in his own person: this nobody has any right to but himself. The labour of his body, and the work of his hands, we may say, are properly his. Whatsoever then he removes out of the state that nature hath provided

* How, for instance, are we warranted in assuming, as a principle of original justice, that an individual can, by his own act of consent, bind his descendants of all future generations? Yet without some such assumption, we could not give to the supposed compact, if real, the complete, the binding validity commonly attributed to it, at whatever epoch we imagine it to have been entered into.

† Grotius—the great doctor, in jurisprudence, of the identical principle which the kindred science of theology acknowledges in the well-known rule, *quod ubique, quod semper, quod ab omnibus creditum est*—seems to have forgotten himself in the application of this principle to the subject of property. Deserting his favourite ground of authority, he resorts to a groundless and unsatisfactory fiction, herein more resembling Puffendorf than his ordinary self. The terms he employs plainly show that the consent alleged by him, in reference to the present subject, is not the concurring testimony of witnesses, but the consent of contracting parties. *De J. B. et P.*, lib. II., c. II., s. III. 5.

Law.

and left it in, he has mixed his labour with, and joined to it something that is his own, and thereby makes it his property. It being by him removed from the common state nature hath placed it in, it hath by this labour something annexed to it, that excludes the common right of other men; for this labour being the unquestionable property of the labourer, no man but he can have a right to what that is once joined to, *at least where there is enough, and as good left in common for others.** The concluding words, which we have marked by italics, deserve particular attention, both because they assert in substance the doctrine of a positive community, which Locke is ordinarily supposed to reject, and because they mark the limit which he virtually sets to the title by labour. His whole argument applies only to that state of circumstances in which the supply of natural objects, unappropriated or in common, exceeds the demands of the comparatively few claimants. So long as this state of things continues, no one can deny that it would be both wanton and unjust, and a dishonest encroachment upon the fair privileges of labour, for any person, under pretence of an equal right, however abstractedly just, to lay claim to any share of what another, without detriment to a single individual, has appropriated and improved. Here therefore we may safely assign some period for the continuance of the right of private property, arising from the intermixture of private labour, namely, whilst the season of superabundance lasts. But does the argument apply, and is it not a paralogism to extend it, to a different state of circumstances, namely, when people have multiplied, and new claimants appear upon the stage, who, finding every thing of possible utility already occupied, demand to know the reason why they—guilty of no neglect in so tardily asserting their claim, but only labouring under the accidental disadvantage of being born, without their own will, in a later age—why they, able and desirous of benefiting themselves and others by their industrious exertions, are debarred from receiving their equal share of things? To say that everything has already become the property of the ancient occupants by the just title of labour, is to assume the whole matter in dispute. Their labour, indeed, did originally give them a title to the things occupied, but (if we would give consistency to Locke's theory, which recognizes a positive community) not absolutely, entirely, and for ever: according to Locke, there must have been from the first a dormant claim for unborn claimants to an equitable share of the things in the mean time occupied, awaiting the coming in of the full tide of population, when, if ever, the claim for the first time would be ripe for assertion. If this claim had any existence, then the original occupants mixed their own property (their labour) with what, *pro tanto*, was the property of others; and according to a recognized principle of universal equity, they must bear the consequences of the voluntary confusion, though it may involve the loss of their labour. The obligation of a re-distribution of property once being introduced, the process must be incessantly repeated, since population is always shifting and increasing. In substance, then, there is an end of private property; and this is the inevitable conclusion at which we must arrive, if we adopt the notion of a positive community of things as a law of nature.

106. Locke saw the dilemma, and endeavoured to

* *Essay on Government*, ch. v.

Law.

evade it by a sophism. He alleges the superabundance, *in the whole world*, of good, but unreclaimed and unoccupied land; for land is the particular subject matter which he chiefly selects. But do not the distant (to most poor people, *inaccessible*) locality, and other disadvantages of those unappropriated lands, violate his own condition expressed in the words "as good"? At last, as if half conscious of the defects in his argument, he adopts the favourite and clumsy expedient of varnishing them over with a tacit compact, which, he says, "settled the property which labour and industry began." Rather let us call it the instrument whereby the disinterested victims of voluntary poverty signed away for ever, and without an equivalent, the right assumed for them to a comfortable subsistence.

Theory of aggregate social utility.

107. Such is the much applauded theory of labour, whereby it is attempted to justify the "rigour of the rights of a proprietor." Such is a specimen of the manner in which theorists burst through the difficulties that beset the subject. There is another class of reasoners, who may be considered to hold the doctrine of a negative community, though they do not either formally state their adherence to that doctrine, or, in general, embarrass themselves with the assertion of any abstract doctrine of justice. They avoid fictions, too; they look chiefly to the practical benefits attending the system of private property, in promoting the good of society *in the aggregate*. Paley enumerates, and admirably illustrates in a few short sentences, the chief social advantages of the institution of property: it increases the produce of the earth, and preserves it to maturity; it prevents contests; and it improves the conveniency of living.* But Paley offers them rather as an apology for the seemingly inequitable, because unequal, system, than as a conclusive argument to justify the assumed rights of individual proprietors. Indeed, for the latter purpose, it would be absurd to allege the preventing of contests, if it be admitted that there are such things as *perfect* rights, (or rights which may be asserted by force,) and that the natural right of property is at once such a right, and a fair subject of difference of opinion. To quiet the violent contest of two honest maintainers of contrary opinions, determined each to assert to the full his own view of his right to a certain object, by capriciously assigning the whole or the greater part of that object to one of the combatants, would indeed be a summary mode of settling the difference, but it would not adjust their claims in point of natural right. Again, no demonstration of the general or aggregate plenty caused by property can account for the justice of its gross inequality, which, let it be remembered, is the point at issue. Paley is not quite candid in asserting a fact, which, if strictly true, would go far towards proving, not indeed that the system of property is naturally just in itself, but that it is just to submit to it. He alleges that even the poorest and the worst provided, in countries where property and the consequences of property prevail, are in a better situation than *any* are where most things remain in common. Without pausing to inquire whether it be proper to compare the relative conditions of individuals under different systems, instead of under the same system, we meet the alleged fact with a direct negative: though generally, it is not universally true. Paley must have been aware that, in all countries, there are several not undeserving individuals, reduced to such

a state of destitution, that it can scarcely be doubted that they would be benefited by a general dissolution of the bonds of property; certainly their comforts would be promoted if they set the laws of property at defiance. When Paley comes to consider the topic of *right*, as distinguished from utility, and when he is driven to confess that the foundation of the right of property is the law of the land! he in truth gives up the question. The law of the land is but the public resolution of those who compose the governing body, and being the resolution of fallible mortals, it may be right or wrong, just or unjust. The tacit compact of society may very often amount to the same thing expressed in a different form. But as all the individuals assumed to be bound by the compact, or by the law of the land, are not in reality parties to the transaction which binds them, whatever the forgers of specious fictions may pretend; until we have some probable proof of the intrinsic justice of the matter agreed upon or imposed, we are at liberty, in a strictly philosophical inquiry, to treat the compact as public chicanery, and the law as systematic violence. Paley ends his speculations on the subject of property, as he ends them on most subjects handled in his shallow book, by referring it ultimately to the "will of God." A truly philosophical mode of proceeding for a professed philosopher! He exposes in glaring colours, without in the least explaining, the apparent injustice of the inequality of property, only, it would seem, to attribute it at last to an arbitrary and, in the state in which he leaves it, unreasonable institution of the All-just!

108. So far as yet appears, it must be confessed, that the modes of arriving at the conclusion are far from satisfactory. In order, if possible, to place the line of argument on a better footing, we shall notice briefly three leading and prevalent defects to which may be attributed, as we conceive, most of the imperfections of the favourite theories.

109. In the first place, those writers who propose the doctrine of equality as a law of nature, rarely understand it fully. Whilst they deny the natural right of any individual to more than his strictly equal share of things, they assert the most absolute, exclusive, and selfish right of every individual to the whole of his own labour, without reference to the relative abilities of himself and others. No reason can be alleged why the principle of equality, if tenable as a law of nature, should be applied to natural material things, and not to labour. Both are essential for the support and comfort of man. Again, the wants of all men are tolerably equal, but their abilities vary. Why then should a person be under a natural obligation to manifest a just consideration for the equal wants of all, passively, by abstaining from an usurpation of more than his just share of things, and not actively, by contributing his just quota of labour? It will be observed that we do not contend for an absolute, but a relative equality; that is to say, an individual who can, with equal ease, effect twice as much as a man of average strength and ability, ought to contribute to the common stock a double portion of the species of labour for which he is best suited; an individual, whose ability falls below the average, should be excused in proportion; each participating equally in the common benefit. This is the true principle of equality. Sir Thomas More perceived it, and has amusingly carried it out in fiction. In practice, it would be neither desirable nor possible to carry it into effect *as a law of*

Law.

* *Mor. and Pol. Phil.* book iii., part i., ch. ii.

Law. *nature*; nor do *we* maintain it as such; but they who do so are rarely consistent with themselves.

The natural and moral laws of property distinguished.

110. In the second place, a confusion is frequently made between natural and moral right, especially with regard to the doctrine just explained. The law of equality is a law of morality, and not of nature. By a law of nature, the reader will recollect, is meant a rule of conduct which is not simply agreeable to the dictates of abstract justice, but suited to the imperfect condition of man; which is provided with an artificial, though a divinely instituted sanction; and which involves a *perfect obligation*, or an obligation which may be asserted by force. The natural law of property, which possesses all these characteristics, is a law of inequality. But it is not inconsistent with the co-existence of a moral law of equality; for whilst the unequal possession of property, for purposes of preservation, improvement, and economy, may be rigidly maintained by force, the ultimate and spontaneous distribution of it, measured by an equitable standard of moral equality, (one element of which is the relative merit of the participators,) may be inculcated by means not violent,—by conscience, or by persuasion, for example. Although, therefore, it be true that there is an equal law of property, they who assert it as a *law of nature*, unconsciously confound the distinct offices of law and religion; for they thereby tacitly assert that public or private force, instead of persuasion or private conscience, is the proper mode of providing for its observance.

The ultimate or moral purpose of property

111. In the third place, the divine purpose of the institution of private property is, in general, very inadequately represented. We speak not of the immediate application and use of material objects, but of the mode in which, and the purpose for which, the possession of those objects is moulded. The objects of property, in themselves, are destined for the physical support of man. The particular manner in which the tenure of them is arranged, (so different where mankind, and the brute creation, respectively, are in question,) in separate and permanent properties, contributes, indeed, more effectually and fully to the temporal prosperity of most men; but chiefly it promotes the moral advancement and discipline of all. That “difficulty is good for man” is a proposition which none can question. But the encountering of difficulties, though a most essential part of moral discipline, is most irksome, and would never, in the absence of some exciting cause, be spontaneously undertaken. The perfection of his moral character demanded that his noblest faculties of thought and action should be aroused and called forth into unceasing and boundless activity; that his energy and power of endurance should be strengthened, and his foresight quickened and enlarged; attainments which, it would seem, are impossible, except as the result of habit and perseverance. His natural imperfection and indolence required the systematic application of natural means. Accordingly, his path, at every turn, has been strewn with multiform difficulties; a necessity for encountering those difficulties has been created by the necessity for labour imposed upon him, even in order to the attainment of every end and purpose connected with his comfort and existence; and a motive to encounter those difficulties has been supplied, in according to him the enjoyment of the objects of his desire, hope, and labour, in the indulgence of the natural feeling with which he embraces his *τὸ ἴδιον*. We have before shown how the concentration of the narrow domestic affections for a time, in the *τὸ ἀγαπῆδον*, con-

tributes to the development of an enlarged love. But it is no less certain that the direct inculcation of a spurious universal philanthropy would terminate in indifference, than that the direct enforcement of a system of vapid equality in respect of property would end in utter indolence. It is for the moralist to enlarge upon, the jurist can only hint, in a general and imperfect way, at the several powers and moral qualities elicited in the different classes of society, through the instrumentality of private property. Let it suffice to observe, that although a well-sustained and honourable course of successful exertion, crowned externally with wealth, is frequently a most healthful exercise to the party who engages in it, the possessors of property are often those who least benefit, morally, by the institution which renders them prosperous. The strenuous exertions called into action in the honest endeavours to escape from poverty, the patience with which it is learnt to be endured, when it cannot be avoided, and the gratitude and sympathy felt and exercised in the receiving and giving of private charity, would in a great measure become dormant, were that system altered which sentences some to poverty.* Upon no other grounds than what are here intimated, can we justify the otherwise inequitable differences of condition which are incidental to the natural laws of property. It is not that philosophical jurists, from the days of Aristotle to the present day, have abstained from even frequently, though partially, pointing out the moral effects produced by property; but they generally treat those effects rather as collateral accidents than as the main cause of the system. They seldom assign them that conspicuously prominent place, which they should hold, in order to become beacons to direct our steps through the tangled thickets of fictions and theories.

112. But it will be said, that property, whilst it encourages exertion, fosters at the same time covetousness and other evil passions. To this we reply that the machinery destined for the best purposes may be abused as well as used; and whilst law keeps it in action, the business of morality and religion is to provide against its abuse.

113. Having endeavoured to establish the justice of property on moral grounds, we shall now show the means by which it becomes a law of nature. In preceding parts of this chapter, we have not been solicitous to avoid the appearance of countenancing prejudice, recollecting that “prejudice engages the mind in a steady course of wisdom and virtue, and does not leave the man hesitating in the moment of decision, sceptical, puzzled, and unresolved;” that “prejudice renders a man’s virtue his habit, and not a series of unconnected acts;” that “through just prejudice, his duty becomes a part of his nature.” Considering that man is naturally more disposed to follow the impulses of feeling than

* Our limits forbid us from entering upon the subject. But here would be the natural place for considering, philosophically, the nice and delicate question of a poor-law, which is a partial attempt to supersede the natural law of unequal property, and introduce in its room a compulsory rule of equality. It would be an interesting, though by no means an easy task, to endeavour to adjudicate between the conflicting claims of morality to encourage individual exertion, and of physical destitution to receive public relief, in lieu of precarious private charity; to establish a just medium between the natural heat of individual beneficence, and the lukewarmness universally attendant on the corporate exercise of every moral virtue, though coupled with the advantage of public example.

Law. to obey the dictates of reason, and that therefore it is of more immediate consequence to influence his will than to inform his intellect, prejudice seems the more proper way of urging him to the adoption of this law of nature. Accordingly, the instinctive sense of property is implanted in him: he feels that he has a right, he knows not why, to keep whatever he is the first to possess. This feeling is born with him, and it accompanies him, with undiminished force, through every period of his life, and through every vicissitude of intellectual and moral attainment. This feeling is common to all men; and therefore, whilst it creates, it protects private property: those who are accustomed to measure their sense of justice by their natural feelings will feel under a natural obligation to respect in others the right which the same feelings prompt them to assert for themselves. Thus *occupancy* becomes the natural foundation of the right of property; and this, whilst the ultimate purpose of its institution is concealed from those who maintain it. And this sense of property will seldom betray them into an unmeaning and unprofitable usurpation of things: in general, they will not appropriate what cannot be used; and they can seldom use what they appropriate, until they have exerted more or less of salutary labour, either in reducing it into possession, or in fitting it for use. Thus the fact of occupancy or possession, being either an evidence of past, or an earnest of future exertion, is rightly made, in accordance with our natural feelings, the commencement of a permanent and exclusive dominion. The gratification of the natural desire of possessing, taken in connection with the innate sense of justice that accompanies the practice and assertion of the right, constitutes a natural sanction of property; it constitutes that original sanction which prompts and enables individuals to become proprietors. A further, more artificial, but still natural sanction, is the good of society—we mean the temporal good,—which is composed of the good of *most* of the individuals constituting the society, not literally of all. This social utility is ordinarily recommended as a proper motive, acknowledged as a sufficient reason, and suggested as a good practical measure, for the adoption, application, and enforcement of the natural principles of property in civil societies. And unquestionably, temporal social utility is a safe every-day standard; but until the view is extended to the higher moral purposes of property, the importance, the wisdom, and the justice to *all*, of this natural institution, cannot be fully appreciated.

Instinctive sense of property.

Occupancy.

Social utility.

National differences in the laws of property.

114. Above we described the chief characteristics of property to be, inequality in the relative amount held by different individuals, exclusiveness of possession, and permanence of enjoyment. The circumstantial varieties, in these several respects, observable in the laws and customs of different countries, have led some writers to imagine that property is purely the creature of civil law. This want of minute uniformity, however, is consistent with a general resemblance in the leading features; and we are not to conclude that, because the laws of two countries may have sanctioned different rules in some particulars relating to property, therefore one or other of them must be so far a departure from or an addition to the law of nature. In England, a local act of parliament is regarded as a part of the public law of the land; philosophically, it comes under the technical definition of a *privilege*. (No. 31.) So, the particular law of property established in a certain country, if

it be the best suited to the habits and feelings of the people, is the local law of nature for that country. It will be seen that the question is a question of terms; it turns upon the applicability of the phrase *law*, which in strictness imports a generality altogether, or nearly co-extensive with the whole community, to a rule of limited application. The community subject to the law of nature is the whole world; in the case supposed, the particular law is not universal, but it has every other characteristic of *natural*. Confining our attention to that which is most general, we shall discover what the law of nature ordinarily lays down, in the several particulars mentioned at the beginning of this paragraph, by considering what rules of property are at once most in accordance with the natural feelings of man, and most conducive to healthful exertion.

115. First, as to the extent of a man's just acquisitions; let us inquire whether any limit in general is set to the amount, by the law of nature. Locke tells us that "Nature has well set the measure of property by the extent of men's labour, and the conveniences of life;"* and Puffendorf speaks very nearly to the same effect.† If an individual assumes to lay exclusive claim to a thing which it would be absurd to appropriate, such as a part of the sea, the water of a river, or an irreclaimable and extensive desert, his claim would be justly treated with contempt. Such things in their own nature always remain in common. A nation, indeed, may appropriate them as against other nations; but there, an useful purpose—such as public security—justifies the public appropriation; which, after all, is not an appropriation in the ordinary sense for purposes of positive use, but rather an exclusion of other nations from doing certain acts within certain limits. Again, an individual cannot reasonably, or agreeably to the law of nature, appropriate such an exorbitant quantity of land or anything else, that there can be no rational probability of his ever being able to turn it in any way to account. This can seldom take place, except in a new country; there, if an individual, who is not restrained by the law of the land from so doing, made the attempt, his claim would not be respected to its full and unreasonable extent. It has indeed sometimes happened that prodigal and useless grants of land were made, (in our colonies, for example,) which are held sacred; but in those cases measure was taken of the *probability* of improvement within some reasonable time, regard being had to the extensive operations of modern civilization, though in the result public expectation was disappointed. To the same principle of unreasonable excess may be reduced the limit that Locke lays down, where he says, that if, before the appropriation of land, a person gathered more fruit, or killed more venison, than he and those whom he allowed to participate with him could consume, so that the fruit rotted, or the venison putrefied, and was wasted, he offended against the law of nature, and might be punished, for he thereby invaded

* *Essay on Government*, ch. v., sec. 36.

† One man is then adjudged to be the occupant of land, when he tills and manures it, or when he encloseth it with settled boundaries and limits: yet still with this proviso, that he grasp at no more than what, upon a fair account, seems tenable by one family, however enlarged and multiplied. Should one man, for instance, be, with his wife, cast upon a desert island, sufficient to maintain myriads of people; he could not, without intolerable arrogance, challenge the whole island to himself, upon the right of occupancy, and endeavour to repulse those who should land on a different part of the shore. *Law of N. and N.*, book iv., c. vi. 3.

Law. his neighbour's share. Waste of this kind will rarely occur to any great extent; but if we can imagine a case where it has become very common, palpable, and excessive, there, probably, direct and compulsory prevention would be neither improper nor unnatural. In general, however, the wrong is a *moral* wrong, or one which ought not to be controlled by law; because considerable latitude must be allowed for the possibility of abuse, on the very same ground that property itself is tolerated, namely, in order that private enterprise may not be checked. By no very violent extension of the principle of interference in case of waste, a person who does not cultivate his estate so advantageously as might be thought possible, might be deprived of all or part of it; this evidently would violate every feeling and every good purpose connected with the right of property. Subject to the limitations we have stated, the bounds of which cannot be nicely defined,—and perhaps, also, under very peculiar circumstances, subject to limitation on grounds of public policy,—the amount of private acquisition ought not to be restricted. If a limit were set, when a person's property had attained its maximum, enterprise, so far as his acts or influence extended, would come to a stand. The unlimited power of acquisition, generally permitted, has a tendency to produce inequalities in the relative extent of private possessions.

Exclusive-
ness of
property.

116. The second point is the exclusiveness of property. Property may be more or less exclusive, according as it belongs to one or to several partners, few or many. Sole property, which is the most exclusive, is also the most natural; both because the selfish feelings of mankind naturally tend more to severance than to union of possession, (we do not speak now of the very artificial unions of modern and highly civilized times;) and because, in general, the interest felt by a sole proprietor is stronger, and consequently the incitement to exertion in improving and preserving his property is greater, than would be the case were there several proprietors of the same thing. In proportion as the number of owners is increased, the interest of each individually is diminished; and as it is not certain that the united interests of all will be made to bear with their full natural force in the same direction, except under very good arrangement, the probability is that the total amount of interest felt will not be so great, as if concentrated in one person; but it is not our purpose here to discuss the artificial arrangements by which this disadvantage may be overcome. However numerous the joint owners of property may be, their right to exclude all others from its use and enjoyment is as natural as the similar right of a sole owner with respect to his property.

Life owner-
ship.

117. Thirdly, we have to inquire what is the natural extent of the right to property, in point of duration or continuance. Jurists for the most part are agreed that the right to property, which involves the rights of using, selling, or giving it away at the pleasure of the proprietor, subsists during his life at least. On his death, does it once more become common; does it devolve upon his children; or does it go to any successor whom he may have appointed? Neither of these modes ought to be gratuitously assumed, as exclusively or peculiarly natural: they should all be subjected to the test of reason and experience, in order to discover which is the most ordinary, probable, and reasonable. The supposition, entertained by some, that a man's property

VOL. II.

naturally returns to a negative state of community after his death, rests on no better foundation, that we can discover, than the purely gratuitous assumption of those, who, in their zeal to simplify the system of nature, make it incomparably more artificial than those more ordinary conditions of things which they peremptorily pronounce, with as little reality of truth as of reason, to be departures from what is natural. Nothing, for example, could be more artificial than the equality of possessions attempted to be enforced by the Spartan law, and by the custom of Tanistry under the ancient Brehon law of Ireland, if we may judge by the necessity that was experienced for occasional state interference, to rectify the inequalities inevitably introduced by time. Or, to take an example more nearly bearing on the matter in hand, the rule of the early feudal law, whereby the feudal proprietor's interest legally ceased with his life, was purely artificial; for, in spite of this positive arrangement, custom, which was only nature re-asserting herself, first established as an indulgence, and at length gradually matured into a right, the practice of inheritance. The same motives and reasons which recommend property itself, recommend its perpetuity; but as to which is the more natural way of perpetuating the proprietor's ownership beyond his life,—by inheritance, or by testamentary disposition,—and even whether the latter be in strict accordance with nature, have been subjects of difference with jurists. The majority decide that inheritance by children is the natural way, and that the power of bequeathing to a stranger derogates from their natural right, and is purely an indulgence of municipal law. If so, its permission is indefensible. In strictness of reason, however, children have no right to anything more than what suffices for a maintenance during the helpless period of infancy, and to put them in a fair way of earning a livelihood at a proper age. This reasonable claim satisfied, the single paramount principle, by which the question must be governed, is THE PROMOTION OF INDUSTRY. In order to give this principle its due effect, we ought to regard not the expectant but the immediate possessor of property. The certainty of succeeding to property, without any efforts of his own, far from exciting the industry of the expectant, tends to relax it. The natural right of the children to succeed to their father's property; then, is inheritance. It is his, because the interest he naturally takes in them is second only—if second—to the interest he takes in himself; and because the feeling that thus prejudices him usefully in their favour—whilst it is a passion which, under due regulation, may be innocently indulged—gives point, energy, and an object to his industrious efforts. By a just extension of the same principle, the utmost possible effect that can be safely accorded ought to be given to the greatest possible number of the natural passions which ordinarily actuate the human breast, excite man to undertake an energetic course of industry, and sustain him throughout it. Accordingly, free indulgence should be afforded to his love of having, upon which depends the right of getting and holding property for himself; to his love of power, whereby he acquires the right of disposing at will of his property, not only during his life, but to any one he pleases after his death; to his love of his children, and, in subordinate degrees, of his remoter relatives, (in general sufficiently just and strong to prevent a capricious abuse of the disposing power,) which gives birth to the rights of inheritance, first of

Law. lineal descendants, and, failing them, of collaterals, but subject to the disposing power above mentioned; and lastly, to his love of family distinction, which originates the right of primogeniture. The order in which these several rights of nature are here named, expresses the order of their relative strength. They may all be reduced to the single right of absolute disposition: if the proprietor names his successor in estate, this is an express disposition; if he suffers his property to devolve on his heir, this is a tacit disposition, since, without any groundless fiction, it may fairly be presumed, from the ordinary course of human affections, that the proprietor's wishes pointed in that direction. Any form or mode, which can fairly be relied upon, adopted by the proprietor to express his intention to dispose of his property, either in his lifetime or after his death, is naturally sufficient: civil laws establish particular set forms, in order to guard against misconceptions and false pretences; and as the real danger of such, or the judgment of legislators respecting the danger of them, varies under different circumstances, nations differ in their established forms of transferring and transmitting property. If to our mode of argument above it be objected, that although, indeed, inheritance by children benefits the parent morally, by adding to the exciting causes of his industry, it at the same time tends to damp the exertions of the children, by encouraging relaxing expectations on their part; we reply, first, that in many cases the inheritance is not more than a fair provision for them; secondly, that where it is more, the absolute power of disposition in the parent partially obviates the disadvantage of certainty of expectation; thirdly, that there would be no alternative but the parent's property becoming common on his death; which, if general, must create too great a facility of acquiring, by reason of the constant supply of property becoming once more common, thereby occasioning a general relaxation of industry, which would extend to the children themselves. The last point here to be considered is, the proprietor's right to forestal the disposing power of his successors by creating entails, or directing some other strict mode of devolution. By allowing this right, on the one hand, the possessor's disposing power is enlarged, and consequently the interest he feels is increased; on the other hand, the power and the interest of his successor will be proportionably diminished; probably with corresponding effects upon the zeal and exertion of each. The mode of adjusting the right, which would give neither of them any advantage over the other, would evidently be to allow only absolute or unfettered dispositions. This mode is the most simple and the most equal, and may therefore perhaps be considered as the most natural. At the same time, we do not mean to imply that family consequence, which is a natural feeling that has its advantages, ought not to be supported by entails. But we cannot enlarge on this topic.

Prescription.

118. We shall close our observations upon property, by explaining how the owner of anything may, by lapse of time, lose his right to it, and how another person may succeed him, as rightful proprietor, by the title of Prescription. We have already (No. 113.) mentioned occupancy as the rightful commencement of property; but the extent of the occupant's ownership must depend upon his intention. If he intends to appropriate the thing occupied only for the brief period of actual occupation, upon his relinquishing it, it becomes once more

common. If he designs to make it permanently his own, as he cannot in all cases carry it about with him, or be present with it, his *animus possidendi*, or virtual and intentional occupation, ought to be made apparent, in order that others may not, in his absence, be induced to appropriate the same thing, under the idea that it is common. To take two extreme cases: if there were no obligation upon proprietors to mark their private property as such, or to assert their right with promptitude, a general carelessness on their part might be the consequence; it might become difficult to distinguish what is common from what is private; and then, as none could know with certainty what they might safely appropriate, few would be willing to apply their labour to that which might be claimed the next moment. The result would be, on the one hand, indolence and laxity; on the other, hesitation and doubt, detrimental to enterprise and industry. If we take the other extreme, the result would not be very different: were the obligation of asserting the right of property so strict as to preclude the possibility of doubt in any case, many would be unwilling to incur the trouble of constantly maintaining their right; and the fear of losing possession, by some accident or oversight of ordinary occurrence, and not always to be provided against—to take advantage of which there would always be abundance of designing persons on the watch—would introduce a sense of insecurity, highly prejudicial to that confidence which is essential to industry. To define exactly the just medium between over-strictness and over-laxity is evidently impossible; indeed the line between them is not invariable, for it will change with the subject matter, and with the prevalent habits and ideas of different ages and countries. We can only lay it down generally, that an appropriator ought to take a fair and reasonable degree of care to indicate the existence of a right of property. Appropriation, however, rarely takes place, without the thing appropriated bearing permanent marks of private ownership. The same argument which applies to things supposed to be strictly in common, nearly applies to things evidently belonging to some one, though the title is either in doubt between two or more, or not asserted by the rightful owner. We will suppose, in such a case, that a person who has no pretence of title, or not the best right to the subject of dispute, no visible owner appearing, takes possession of it, and is suffered to continue for a length of time in undisturbed occupation: we have to consider what effect ought to be attributed to lapse of time in such a case. Putting out of view the temporal interests of the parties immediately concerned, it is of no importance, socially or morally, how property commences, or who is the proprietor. But it is of vital importance, both socially and morally, that a right of property once commenced in any individual should not easily be disturbed; for the permanent security of property is only another name for the encouragement of permanent and progressive industry. Therefore, on general principles, it is desirable to allow the largest space of time that can be in reason desired, or with safety granted, for the lawful proprietor to recover his property. But this time must have a limit; for so long as the lawful owner neglects to assert his claim, the unlawful possessor continues in a state of suspense, between hope that the other may never claim his own, and fear that he may; and this state of suspense discourages exertion, and ought not to be continued for ever. As time advances, the hope will

Law

Law.

gradually become stronger, and the fear weaker; and this growing confidence will exhibit itself in an increasing disposition, on the part of the occupant, to treat the property as his own, and to give it all the improvement he can, which it is capable of receiving. To disappoint him, by robbing him at last of the fruits of his exertions, would be to check similar exertions in parallel cases, the moral and social mischiefs of which need not be enlarged upon. Turning now our attention to the relative claims of the parties, regarded as individuals, to a just share of consideration; the occupancy and the right of the lawful owner (as we may still call him for the sake of distinction) originated perhaps in the accident of finding the property lying in common; the occupancy of the other originated in the wilful neglect or forgetfulness of the lawful owner: the moral reason for the lawful owner acquiring a permanent right of property at all, consisted in the probability that his right of property would act as a spur to exertion, a probability unfulfilled in the event; the moral reason for the intruder becoming in time the rightful owner is the certainty that he occupies the place which the other ought to have asserted, of a vigilant and industrious proprietor, in will at least, if not in act. Lastly, the enjoyment of the property, if considerable, becomes, in process of time and by habit, essential to the comfort of the intruder, and a part of his nature; and it ceases to be so with the other. From these several personal considerations, in addition to the public and moral grounds above stated, we conclude that the title by prescription or lapse of time ought at length to prevail over an originally better title. If it be asked what is the natural period of prescription? we answer, that it is not uniform, nor ever can be, until there is an uniformity in the prospective and retrospective habits of all mankind; until the time for superinducing forgetfulness and begetting confidence is the same throughout the world; and until the arts of life are equally known, and the time for bringing them to maturity is the same everywhere.* We have now stated, in general terms, the philosophical foundation of the prescriptive right of property. The original owner may claim his property at any time within the period of prescription. Particular circumstances may have a natural tendency, and have been occasionally allowed to operate, either to prolong or to abridge the ordinary period. The infancy of the rightful owner, whose infancy excuses his neglect, is an instance of the former: the fact of the lawful owner, fully aware of his title, standing by in silence, whilst improvements are carried on by the intruder, is not an unreasonable ground for the latter, or rather for presuming his consent to the assumed ownership of the other.† There is one material consideration, which must not be omitted,

*The periods of prescription have varied excessively in different countries and ages. We may give a few examples. By the early Roman law, a period of one year for moveables, and two years for immoveables, was fixed. In our own law, the periods of prescription for different purposes have frequently been varied; at present the period of prescription, in regard to lands, is, in general, twenty years. By the Hindoo law, an uninterrupted possession for three generations confers an absolute title to lands; an occupancy by three successive owners, for sixty years in the aggregate, counting as an occupancy of three generations. The period for moveables is commonly shorter than that for lands; because the former are apt to pass through a greater number of hands in a given time than the latter.

† This is the ground taken by Grotius, who founds the right of prescription in a tacit abandonment. *De J. B. et P.*, lib. ii., c. iv.

viz., the honesty or dishonesty of the intruder, when he takes possession: there is a wide difference whether he comes in under an honest though erroneous impression respecting his right; or with a full knowledge, or strong suspicion, that another is the rightful owner. Puffendorf, in common with several other writers, considers honesty to be so essential, that the intruder himself can, by no lapse of time, purge away the original infirmity of his possessory title, but that he must be succeeded by some second holder, (an heir or alienee,) who was not aware of the dishonesty; from the commencement of whose occupation the period of prescription is to date.* Puffendorf, we are inclined to think, lays down the rule too absolutely. Doubtless, the dishonesty of the intruder is an element to be considered, along with the other grounds above described; but we are not sure that, even in spite of dishonesty, time ought not, on those grounds, often to prevail in "mellowing into legal right" an usurpation of property "that was violent in its commencement." The shades of moral and natural dishonesty, between a full consciousness of another's title, and an utter ignorance of it, are infinite; and there may be great moral culpability in the negligence of the former owner. Lastly, it is to be observed that the right by prescription is sanctioned by a strong instinctive feeling or prejudice of our nature; and, in point of authority, the universal practice of mankind, in every age, has been to respect it.

119. Those who, following the arrangement of the Natural Roman law, adopt the natural law of facts as one of law of facts. their chief divisions, investigate, under that name, the several facts upon which legal obligations and liabilities are founded. Under this head, they examine most of the principles of civil and criminal justice, and treat the copious subject of contracts. Our plan does not exactly coincide with theirs; nor does our allotted space allow of a minute discussion of the several topics they examine, especially that of contracts, which has been so ably and so fully handled in the Roman law. We may here briefly remark that in the endless conflicts and transactions of human life, there is a daily necessity, as well as opportunity, for the exercise of man in the practice of the two eternal principles of JUSTICE, and GOOD FAITH, or TRUTH. The natural principles and measure of human justice must be collected partly from the preceding discussion of relative obligations, and partly from the few remarks about to follow in the next section.

120. Good faith, or truth, relates either to speech or Truth. to action; it prescribes the avoiding of all deceit, and the faithful fulfilment of every engagement. Writers Its moral obligation. universally concur in treating the obligation of observing it as a postulate in morals; but the mode in which it is developed in the law of nature is worthy of observation. What we wish to point out is the universal recognition of degrees of obligation respecting it; for although no limit can be set to the moral duty of truth, yet, in human estimation, some kinds of truth are held in more solemn respect than others. Additional circumstances of outward solemnity,—amongst which we Its natural degrees. may particularly distinguish a direct appeal to the Supreme Being,—are held to impart an additional degree of sanctity and efficacy to truth itself. Yet are not the bare intention to deceive, and the breach of any engagement, highly culpable violations of this great moral

* *Law of N. and N.*, book iv., ch. xii., 4.

Law.

principle? Men, however, in all ages, have made distinctions; some even, who have no regard whatever for their bare word, exhibit no small respect for their oath; and all acknowledge that the latter is *more* binding. Again, with respect to contracts: some are considered to have a more peculiarly stringent obligation; those, for example, which are of a more equal reciprocity, with reference to the relative degree of advantage thereby secured to each party; and this wholly independent of the certainty and freedom of the engagement and the expectations thereby raised.

Natural sanctions of truth.

121. If it be asked, why this is so? we may probably (for it would be unbecoming to speak with dogmatical certainty on such a subject) here apply the same principles and reasons, previously offered in explanation of the duties already disposed of. Man requires to be practically disciplined in the observance, in order to the love, of truth. As his attainments in this, as in other instances, must be gradual, truth has been accommodated by the law of nature to his imperfect condition. His mind, accordingly, has been naturally impressed, through his instincts, with an artificial esteem for certain kinds and modes of truth above others; and the Author of Nature has made the observance of them especially important to the temporal welfare of human society. There is then a certain kind and degree of truth, respecting which the law of nature leaves us but little choice; which all mankind, but the very lowest, venerate; and which, from interested and worldly, but not therefore improper motives, is vindicated by human laws. But higher and more complete degrees of truth are left, as they must be left, both in nature and in law, entirely free and unimpelled.

Use of oaths, &c.

122. There are some natural and legal obligations, in themselves abundantly important, to which a further sanction is commonly added by the imposition of an oath or other solemn engagement. We may instance the duties arising from the relations of husband and wife, and sovereign and subject. In such cases, the independent or original causes of duty ought alone to be sufficient to impress the parties with a practical sense of obligation; but as those causes often are either unknown, or not readily borne in mind, advantage is taken of the plain and obvious obligation of truth, to effect the practical object in view by an additional and different species of obligation. Thus truth aids the observance of other duties; and other duties, where the independent reasons of them are practically recognized, aid the observance of truth: for the mind will not always discriminate which of the two concurrent obligations predominates. But caution is necessary in thus uniting truth with other obligations; for there is a tendency in the human mind to measure by each other two obligations united in the way supposed: if, on the one hand, it sometimes happens that a duty of but secondary moment is elevated to excessive importance by the addition of a solemn oath, there is a danger, on the other, lest the estimation in which the oath is held should be depressed to the comparatively low level of the duty it is intended to strengthen. It follows that the interests of truth forbid the imposition of oaths on trivial occasions; and the same principle ought to be extended to all solemn engagements.

Practice of alleging tacit compacts.

123. The preceding remarks suggest one concluding reflection. Scarcely anything can be less philosophical than the practice of alleging tacit compacts as the sole or chief foundation of certain social and political obli-

gations. No one will deny that compacts must be observed; but from philosophers we are entitled to know what is the original and independent obligation which thus calls for and justifies ratification by a solemn compact. We are not to be deluded by the trick of substituting the obligation of good faith (which, in many of the cases supposed, has no existence, and if it has, can be no substitute) for the *fundamental* obligation, which such philosophers do not condescend to investigate. Possibly, the practice may have partly arisen from an undue preference given to truth above the *co-ordinate* and *co-equal* principles of love and justice.

Sect. 5. *Of the enforcement of the Law of Nature by mankind, in civil society.*

124. In the preceding section we have attempted to give a rough sketch of the principal obligations of the law of nature. That law, we have seen, is a particular measure of conduct, adapted to the present condition of man, and calculated to promote his moral advancement; and its sanctions, or the natural means by which it is pressed upon him, include instincts and motives of self-interest; gradually ascending, however, and mingling themselves with care for the public welfare, and with reason and conscience; thus both rendering him less selfish, and tending to that state of spontaneous action, which it was observed (Nos. 52. 53.) is essential to perfection. So far, this law is the law of nature. We have now to consider it as the subject-matter of human law, or as receiving an additional sanction and protection at the hands of men by means of human punishments.

125. Though the force and power of its natural sanctions will never permit the law of nature to be wholly disregarded, yet the freedom which is indispensable to man's moral character, and to his progressive advancement as a moral being, requires some degree of laxity in those sanctions, and consequently some liability to error on his part. Had the mechanism of instincts been carried much farther, greater regularity of conduct, indeed, might have been produced; but it would have been the mechanical regularity of brutes, not the orderly virtue of free agents. Again, a more extensive employment of superior motives,—those, namely, which act upon man's sense of aggrandizement, which operate through the noble faculty of reason, and call forth much intelligence, knowledge, and foresight,—would, in all probability, only have made him a more highly cultivated intellectual machine, and confirmed him in selfishness. These several moving powers have probably been employed as far as they could be with safety or advantage, room being still left for the free play and final supremacy of the moral sense. But the liberty so far accorded to man, whilst it is the cause of his greatness, is also the source of much disorder. A necessity still subsists for further direction and control, but of a different kind, the direction and control, namely, of an intelligent agent; and these are provided in the power which is administered by man himself.

126. In treating of human compulsion, we will consider, first, the species and principles of interference; and, secondly, the organization of the authority which directs it.

127. I. The duties of men towards each other, or the rights answering to those duties, form, if not in strictness (as some contend) the only, at all events the most common and indisputable subjects of human enforcement. But in order to be enforced, they must

Law.

Laxity of the law of nature.

Enforcement of relative obligations.

Law. be certain and definite, with respect both to their extent and objects; and they may either be so naturally, (that is, in a manner too plain and obvious to all to require any further definition,) or be rendered so artificially, by the private contract of the parties interested, or by the laws of states. Accordingly Nature, Contract, and Law are said to be the three sources of perfect rights.

Modes of exerting force. 128. Next, as to their enforcement. Human force is exerted to obviate the injuries resulting from a violation of them in three ways: 1. in self-defence, to repel *present* injuries; 2. to compel reparation for *past* injuries; and, 3. to prevent *future* injuries, by the punishment of the wilful violators of such rights.

Self-defence. 129. The right of self-defence is more comprehensive in a state of nature than in civil society. In the former, every individual is the protector of his own rights, with respect to the future as well as to the present. But in civil society, private individuals are permitted, and that from unavoidable necessity, to use violence only in the immediate defence of their persons or property; all steps for their future security being reserved for the public authorities. With respect to *present* self-defence, which we have now to consider by itself, its just limits, we conceive, whatever some writers may assert to the contrary, are precisely the same in civil society and in a natural state. This right, as Grotius observes,* arises directly and immediately from the care of our own preservation, which nature recommends to every one, and not from the injustice or crime of the aggressor who may threaten our safety. So that if a person, involuntarily, or by mistake or accident, assaults me, or in any way places my life in imminent danger, I am not to be debarred, by the consideration of his innocence, from consulting my own safety, even at the expense of his life. The law of charity does not require me to have a *greater* regard for him than for myself. But, on the other hand, the same law requires that I should not have a *less*. If, therefore, my own defence will probably do him a greater injury than he will do me, I should submit to be the sufferer. This is the broad and intelligible rule. Jurists sometimes introduce other collateral or subordinate considerations, which we cannot here examine, to modify the right of self-defence under particular circumstances. Cases of this kind, where, without any blame attaching to either party, the sacrifice of one or other of them becomes unavoidable, are of rare occurrence, and fall more properly within the province of casuistry than of jurisprudence. The right of self-defence, as jurists commonly treat it, relates principally to the repelling of wilful and malicious assaults. Puffendorf,† and others after him, contend, but assuredly with very inadequate notions of the obligations of humanity, that the unjust intention of the assailant, however slight an injury he may attempt, deprives him of *all* title to consideration; and that, therefore, although it may sometimes be more *prudent* for the party assailed to submit to a trivial wrong, than to avert it by the death, even, of the assailant, there can be no *obligation* upon him to that effect. Where then should the line be drawn? The limit of rightful self-defence is, we conceive, identified with the limit of just punishment (of which presently, No. 134); that is to say, whatever would be the utmost amount of

punishment that could properly be inflicted for the crime apparently intended, supposing it to have been completed, to that length of harm the right of self-defence may be justly carried; beyond it, the obligation of endurance begins. Such appears to be the principle recognized in the laws of most well-regulated communities, which rarely suffer with impunity any crime to be prevented by death, unless the same, if committed, would also be punished by death.* And thus the defence of life, limb, or chastity has, in all or most countries, been held a sufficient justification for the taking of life. But it must be understood that the party assailed is in no case privileged to proceed even to the length we have stated, unless it be absolutely necessary for his own immediate safety. It may be objected that the limit drawn is merely theoretical, because in the hurry, danger, and excitement of the moment, and moreover where self is in question, it is rarely possible to weigh the matter very nicely. However we have only attempted to describe generally what is strictly and rigidly *justifiable*. Some excess must always be *excused*, provided it does not surpass the fair allowance claimable on the score of ordinary human infirmity, and become an act of cruelty; in which case the gross excess would be a just ground of punishment. It only remains to be observed that, as a general rule, whatever violence an individual may lawfully exert in his own defence, he may equally exert in defence of another person who stands in a near domestic relation to him.

130. So far as to the repelling of an injury before it can be carried into effect. When an injury has actually been inflicted, it may be viewed in a two-fold aspect—Distinction between civil injuries and crimes. as it may be repaired, and as it may be punished. In the former aspect it is called, in the language of jurisprudence, a *civil injury*; and the object of reparation is to place the injured party as nearly as possible *in statu quo*, with reference to the past. In the latter aspect the same wrong is called a *crime*, and is made the subject of punishment with a view to prevent the perpetration of similar injuries in future.

131. With respect to reparation; the civil injury, Reparation. upon which a right to it is based, is not, as in the case of self-defence, necessarily of a violent character; nor is it always attended with criminality. A right withheld, whether in ignorance or otherwise, or a wrong attributable in any degree, however slight, to neglect or carelessness, is such an injury as will give the sufferer a right to reparation from the person who has thus caused it. The claimant, however, must not himself be in fault; and he must prefer his claim within a reasonable time after the injury has happened, otherwise a hardship might be inflicted upon the other party, by subjecting him to an unexpected and stale demand. The period for preferring the claim must depend a good deal on the subject matter. As to the mode of reparation: where the injury consists in the withholding of some specific right or thing, restitution in specie, if practicable, is obviously the proper remedy. Where this mode of redress is impossible or inapplicable, compensation in value ought to be rendered. Lastly, where redress of the proper kind and amount is denied, it may be extorted by force; but, in civil communities, private individuals are not allowed to exert this force for themselves, but must obtain redress through the civil tribunals constituted for

Law.

the purpose. The statement of these leading principles must suffice on this head; for our limits will not suffer us to go into the details, which are complicated and difficult.

Crimes and punishments.

132. We have now to consider injuries as they become crimes. The circumstance which makes an injury a crime, and calls for the punishment of the criminal, is his guilty knowledge, or the wilfulness of his offence. This affords a just ground to apprehend from him and from others the perpetration of further injuries; from him, whose evil disposition has been already sufficiently manifested; from others, who may be instigated by his bad example. Punishment, therefore, is inflicted upon him with a double view; as a check upon him, and a check upon them. So far as it is intended as a check upon him, the punishment may be of two kinds; either such as incapacitates him physically from repeating his offence, by depriving him of the power or opportunity of doing hurt, as, for example, perpetual imprisonment, or death, or banishment to a distant part of the world; or such as tends to reform his character and make him a better member of society, by the wholesome fear it produces in him of incurring a like punishment again. The former kind is proper for heinous offenders, whose crimes afford proof of an incorrigibly bad disposition, incapable of being acted upon by any moral restraint; the latter for less atrocious offenders. The same punishment, of either kind, operates upon others by the force of example; and in order to give it effect in this way, it should be made as public as possible. It is also frequently necessary to add to its severity, as compared with what would suffice to restrain the individual culprit merely. Thus, though perpetual imprisonment will always be an effectual protection against the designs of any given offender, however dangerous, nothing less than death may be sufficient to strike terror into some whose evil disposition has not yet broken out into open crime. On account, then, of public example, punishments are usually adjusted less according to the nice measure of each individual culprit's depravity than according to the general experience of their efficacy. The extent of punishments, however, with this or any other view, must be limited by considerations of justice and mercy towards the offender, of which presently. We have only now to add that the efficacy of every punishment depends much upon the speed and certainty with which it follows the offence.

In what sense punishments are inflicted for the benefit of the public.

133. Punishments are said to be inflicted for the benefit of "society," "the public," or "the community." Each of these terms is ambiguous: it may designate either the individuals composing "the public," &c., considered as individuals, or the same persons collectively "in their social aggregate capacity,"—in other words, the state. Those who, like Blackstone,* endeavour to make all crimes turn upon a supposed injury to the state, misrepresent the matter. His distinction between a civil injury and a crime consists, it would seem, in the former being a (past) injury to an individual, and the latter being a (past) injury to the state. Is an individual murdered?—the state has lost a citizen, and fears that it may lose more, and therefore it punishes the murderer. But what is the case in theft? Here the state suffers no loss, no diminution of its power or resources, though

some of its wealth passes, dishonestly it is true, from the hands of one citizen to another; and yet it punishes the thief. But, in truth, the primary distinction between civil injuries and crimes, as we have already mentioned, consists in their relation respectively to the past and the future. The distinction of private and public, which also belongs to them, is secondary, and in some measure accidental. In far the greater number of cases,* a private individual is the only immediate sufferer by a crime; therefore he alone is entitled to civil satisfaction; but when he has obtained it, he has obtained only part of that to which, as an individual, he is entitled, namely, reparation for the past. He has still a right to protection for the future; but here he no longer stands alone; for all other individuals of the community, as individuals, and not in their collective capacity, participate in the same danger, arising from the very same cause, and have therefore an equal right to protection in the same way, namely by the punishment of the criminal. As all then are equally, though separately, interested in his punishment, there is a peculiar propriety in the action for that purpose being instituted in the name of the sovereign, as the *parens patriæ*. The fiction according to which the wrong is said to be done to the sovereign (who is often confounded with the state) is explained by considering the interest he has in his subjects' welfare to be paternal rather than beneficial; consequently his interference is not on selfish grounds.

134. We shall now say a few words on the principles which ought to regulate the proportion of punishments. It does not follow, because prevention is the end, and the only end,† of punishment, that therefore it may be pursued at any cost. It is now pretty generally admitted that neither the difficulty of preventing a particular crime, nor its frequency, nor the number of persons interested in its suppression, will, either separately or jointly, justify the use of preventives disproportionately severe. In such cases it is the duty of society rather to tolerate the partial inconvenience arising from an imperfect check. There are two distinct measures of just punishment: the depravity of the offender, and the magnitude of the evil that would result from his unpunished offence. As to the first, it is unnecessary here to exhibit in detail the various circumstances which are ordinarily taken as proofs of an offender's depravity of heart: they will readily suggest themselves to most readers. In proportion to his depravity, as evidenced by his crimes, an offender's title to consideration diminishes, and, as it would seem, wholly ceases when his crime is of a nature that evinces a state of utter and hopeless depravity. It then becomes lawful to put him to death for the sake of public

Law.

* Not in all: for some criminal acts, such as treason and sedition, may be directly levelled at the state, and these are punished for the future safety of the state as such. Everything relating to punishments on this latter ground, properly falls within what is called public law (public being here used in the second sense, explained in the beginning of the paragraph). Punishments for the protection of private rights, which are the only ones contemplated in the text, belong to private law. The distinction between public and private law is thus expressed in the *Digest*, l. i. 1, 2:—"Publicum jus est, quod ad statum rei Romanæ spectat: Privatum, quod ad singulorum utilitatem."

† Some, without much attention to verbal accuracy, contend for retribution as an end of punishment. A palpable mistake; since retribution is but another expression for punishment itself. They probably mean to refer to the measure.

Law.

example. Grotius, in his admirable chapter on punishments,* mentions the opinion of several philosophers, that possibly death may sometimes be expedient even for the sake of incorrigible offenders themselves, since, apparently, a prolongation of life can only serve to harden them still more. This opinion, however, he advances with becoming diffidence, and at most as a conjecture. Some, rather too hastily, contend that depravity ought to be the sole measure of punishment. However, we ought not to overlook the other measure above mentioned, namely, the magnitude of the evil contained in the offence, which will frequently compensate for a total or partial absence of depravity. Of course it is not meant that punishment should ever fall on one who is not a voluntary agent. To warrant punishment, there must at least be an antecedent and known responsibility, with a power in the agent of commanding his own actions. Under these circumstances, it is still very possible to occasion the most deplorable mischief, without any depravity of heart. We may instance, as an example, a sentinel sleeping at his post, overcome by *almost* involuntary drowsiness, whereby the safety of an army is compromised. For such a crime death may be justly denounced, supposing that no lighter punishment is found effectual to secure vigilance by timely exertion; because here the question rests between the lives of *many* innocent persons, and the life of one or a very few offenders in this way, who know beforehand the magnitude of the interests entrusted to them, and the consequences of their conduct. This single instance will suffice to illustrate the principle. It is not allowable, however, to impose artificial obligations of this kind without a strong necessity for so doing.

Offences
against
self.

135. Hitherto our attention has been exclusively devoted to offences against the rights of others. The offences which a man may commit against himself are in general, as such, unfit subjects for prevention by punishment; not because every man has an abstract right to do what he pleases with himself, (than which nothing can be more untrue,) but because an inquisitorial visitation of the private morals of individuals would be detrimental to their independence of character, which is connected with all that is truly great and noble in their nature. But immoralities which would be passed over with impunity, if committed in private, are properly made subjects of punishment when done in public, on account of their evil example. There are, however, some crimes of the present class too gross and detestable to be tolerated under any circumstances: these form exceptions to the general rule. This observation applies to suicide, the greatest offence a man can commit against himself. It is curious to observe how some writers, fettered by a false or overstrained notion, that with the conduct of individuals, as such, society has no concern whatever, go out of their way to find reasons or excuses for preventing this crime, when the true and only tenable ground is so plain and obvious, viz., the tremendous and irremediable injury the self-destroyer commits *against himself*. The loss of a citizen to the state; the grief, distress, or loss he occasions to his family; such are the frivolous grounds often put prominently forward—reasons which, it may safely be affirmed, never would, by themselves, have induced society to interfere. In fact, upon this,

as upon other points, the instinctive feelings of men, which are generally condemnatory of suicide, appear to have informed them much more truly than their reason.

Law.

136. Observations nearly similar to the preceding will apply to offences against God and religion. It is the duty of society to provide the means of inculcating upon its members the performance of their obligations in this respect; but, in general, compulsion is an improper instrument for the purpose. Punishments are wholly improper for enforcing duties of *performance*, and they must be sparingly and cautiously used as a preventive of what is positively injurious. As the temporal welfare of men in society is but an auxiliary, and ought not, therefore, to be made the substitute of their moral and spiritual welfare, we can regard the political and social benefit of religion only as a natural inducement, and not as the ultimate reason, for society's interference for the defence of the outworks of religion. But whether we take the religious, or merely the temporal ground, the limit of interference will be the same. The rule is toleration, and the exception interference. Grotius, with his usual good sense, draws the line where this toleration ought to cease—of course it cannot be done with exact precision. In the cases where he considers interference to be justifiable, not only are the external interests of society vitally implicated in the suppression of the offences proscribed, but there is no undue interference with the most extensive freedom which can be rationally claimed. Those cases may be thus enumerated: the public propagation of downright atheism (see No. 90); the open worship of confessedly evil spirits, under the notion that they are such; human sacrifices; open and wilful profanity.*

Offences
against
God and
religion.

137. We may not improperly conclude this division of the subject with two observations. The first relates to a topic alluded to in a former page (No. 38.), respecting the supposed superiority of punishments over rewards, as inducements to right conduct, and properly reserved for this place, because we were not then treating particularly of *artificial* inducements. The means possessed by civil governments for the ordinary control of their subjects' conduct consist exclusively of punishments (for we ought not to reckon the honours and rewards bestowed for rare and distinguished merit). Some, therefore, have chosen to assert that rewards are, in their own nature, less calculated to influence *the conduct*. But this does not seem to be the case. The objection, in a moral point of view, to an excessive use of artificial rewards seems to be this: that while they may equally influence *the conduct*, they are calculated to give permanence to artificial *motives*, and so to impede progress towards that *spontaneous* course of action in which moral perfection consists. When punishments are the inducements made use of, in proportion as the conduct becomes more and more correct, the necessity for their application becomes more rare, and the sense of their presence more faint; until at length they silently and of themselves practically cease to operate, though retaining their dormant power unimpaired. But rewards, when employed for the same purpose, must be constantly accumulated upon the agent, in proportion as his conduct becomes habitually conformable to the rule proposed for his observance; the natural consequence of which must be to enslave him to them. Now the great object of man's life being the cultivation of

Punish-
ments and
rewards
contrasted.* *De J. B. et P.*, lib. ii., c. xx., sec. 7.* *De J. B. et P.*, lib. ii., ch. xx., sec. 44—51.

Law. both his conduct and motives, with a view to his ultimate perfection, which perfection imports freedom from all necessity for outward constraints or inducements, we may, upon the grounds here intimated, partly account for the Deity having placed punishments rather than rewards at man's disposal, as the ordinary means of guiding the conduct of his species.

Probable ground of man's right to punish.

138. The other observation relates to the probable reason for conferring the administration of these punishments and of the other modes of lawful violence above explained, upon *man*; who, it may perhaps be thought, is but imperfectly qualified to administer them with just discrimination, and in danger of contracting a hardness of heart from the constant habit and necessity of putting them in force himself. But what might at first seem objections to, are perhaps the very reasons for, the delegated authority thus conferred upon him. Without the power to discriminate between good and evil, and without—we do not say the *hardness*, but—the *firmness* of heart to exercise severity upon just and necessary occasions, his moral character must be essentially imperfect. Probably it was to rectify his errors, and to supply his weaknesses and defects, in both these particulars,—in a word, to teach him *justice*, not as a mere sentiment, nor as an expedient for his present regulation, but, practically, as an energetic and eternal principle of action,—that the task has been imposed upon him of himself discovering and defining the limits of his own rights, and of inflicting evil upon evil-doers, as the only means of preserving those rights.

Civil government.

139. II. The second division of the subject which we proposed to discuss (No. 126.), relates to the organization of the compulsory power possessed by men for exacting a due observance of their perfect obligations. The only way in which this power can be effectually exerted is, in civil society, under the permanent and systematic direction and control of one or a few individuals exercising exclusive and supreme authority over all the other members of the community. Though, in conformity with established usage, the expression *state of nature* is employed to denote a state of things opposed to civil society, yet, as it has been frequently observed, the latter is, in truth, the natural state of men, because it is their ordinary condition in all ages, the state in which Providence designed that they should live, and one which they are as surely and unerringly led by their natural wants and instincts to adopt, as property, marriage, or any other institution confessedly natural. The circumstance that some voluntary act on their part is necessary at first to establish the relation of sovereign and subject, does not in the least detract from its natural character; unless we choose to say, that property and marriage are not natural, but adventitious, because they originate respectively in the voluntary acts of occupancy and consent. (Nos. 98, 113.) Indeed it would be difficult to name any natural right, which has not, in some respect or other, a voluntary commencement.

Ends of the institution of civil government.

How then does the right of sovereignty begin? Before attempting to answer this question, it will be desirable to have a clear and correct notion of the *ends* to be answered by the institution of civil government. Now a mistake is very commonly committed in supposing the furtherance of justice to be ultimately the sole end; as if (to borrow an expression of Hume*) obedience to civil government were a *new* and *fictitious* duty, invented to

support the *primitive* and *natural* duty of justice. Law. The cultivation of the habit of obedience or submission is itself an independent and co-ordinate object, essential to the perfection of man; who, as a created and finite being, must for ever be dependent on the will of his Creator. Now right submission does not imply an abject and idolatrous deference to mere *power*: to be genuine or praiseworthy, it must be based upon an intelligent and right apprehension of the *wisdom* and *goodness* of Him to whom it is due; uniting the two opposite, and seemingly contrary, qualities of independence and deference;—of independence, inasmuch as such submission is freely and willingly, and rationally yielded; and of deference, because, though not blind, it is profound and implicit. Next, with respect to the mode of cultivating and gradually developing this manly principle; a necessity of habitually bending to the will of some visible ruler materially tends to render men submissive. But were this ruler greatly their superior in wisdom and goodness, his superiority would probably awe them into an undiscerning and childish subjection, with but little prospect of advancement or improvement, or union with manly freedom. If again, without any such superiority in wisdom or goodness, the person of their ruler, and the precise commencement, termination, and extent of his authority, had been so exactly and manifestly defined by the Deity, as to leave no room for doubt or mistake, it is not difficult to divine the probable result:—men, ever prone to run into one extreme or other, would permanently become, in heart and disposition, either abject slaves or downright rebels: for unqualified submission could scarcely be rendered to such a ruler as last supposed without a wilful blindness to all his imperfections, or rather, perhaps, without a total surrender of all freedom of thought and action; and yet, in the face of an authority so unquestionable, to venture upon any the slightest or fairest criticism of his acts of government would be to stand clearly self-convicted of undutiful disaffection. It was probably with a view to avoid these extreme consequences, but at the same time to afford men proper and fitting objects and opportunities for the cultivation of the virtue of submission, that they have been subjected to the rule of individuals of their own species undistinguished from the mass by any extraordinary natural endowments, and that a certain indeterminateness, not apparent, but real, hangs over every thing connected with the natural origin, extent, and limits of human sovereignty.

140. If the preceding argument be well founded, it is idle to refer the origin of sovereign right exclusively to any one definite mode of commencement. Without either affirming or denying absolutely any of the favourite and conflicting theories on the subject, it will suffice to observe that there is much of truth in each of them, in the most slavish, as well as in the most licentious. When carried to their extreme lengths, or adopted exclusively, they either become objectionable, or afford but a very lame and imperfect account of the matter they profess to clear up. The doctrine of a Divine Right affords no explanation whatever of the legitimate mode of acquiring a title to sovereignty, or of the just limits of sovereign power: when properly understood, it implies nothing more than what every believer in a superintending Providence must hold: as for the stolid and extravagant lengths to which it was formerly carried, nothing will be expected from us here. Some derive civil from parental authority. This specious but fanci-
Origin of sovereign authority.
Divine right.
Parental authority.

* Essay on the Origin of Government.

Law. ful theory (so far as it applies to the title of modern dynasties) has been completely disposed of by Locke; nevertheless many still pertinaciously adhere to it. Let us see what they profess to tell us. That originally the parent, himself independent, ruled over his own children; that by degrees his family increased into a tribe; and at length, from a tribe, into a nation; and that the power, which he at first wielded as a father, naturally expanded itself, in him or his heirs, into the authority, first of a chief, and then of a king. So far, well. But why stop there? Why not carry the history on to its natural conclusion? In process of time, this kingdom becomes too large and unwieldy to be governed by one man, and falls to pieces by its own weight; or sections of the people separate from the parent stock, and set up for themselves; or else the people become dissatisfied with their sovereign, and, justly or unjustly, depose him and his immediate family. In all these cases, some new expedient must be hit upon, to procure a legitimate sovereign. But it never will be pretended that none but the next heir in succession of the original progenitor is capable of lawfully succeeding, for this would be to brand with illegitimacy, in all probability, every sovereign of the present day: and yet such must be the conclusion, or else the theory, as an universal theory, means nothing. Another favourite mode of making out the right of supreme dominion commences by asserting the original independence of all men; a state which is put an end to by their own voluntary choice and consent, each individual transferring the natural power he possesses to one person, whom all agree to treat as their common sovereign. It is curious to observe how this pretended natural independence of mankind, which is made the foundation of a right by delegation, might just as readily be made the foundation of a right by assumption. This will appear evident, when we consider that complete independence implies two things, an unlimited right of self-protection, and an unfettered right of private judgment. Now the rights of no individual can receive full protection, without the regular and systematic punishment of all offences by whomsoever and against whomsoever committed (No. 133.); and this implies the exercise of sovereign functions. So that any naturally independent individual has a perfect right, if he only has the ability, to assume supreme and exclusive authority over all. In exercising sovereign functions, he does only what is necessary for the full protection of his own rights; and in preventing the application of any other form, rule, or measure of enforcement, except his own,—in a word, by assuming and maintaining exclusive dominion, he merely asserts his right of private judgment. Thus, according to the doctrine of natural independence, might becomes right.

Parallel between government and property. 141. A strong analogy holds between the dominion over persons, and the dominion over things; only the comparison must not be pressed too rigorously. It is with government, as with property, of very little moment how it commences, or in whom it becomes vested; but it is of the last importance, that, once completely vested in a particular individual, it shall not easily be disturbed. Occupancy, we have seen (No. 113.), is the origin of the right of property, the natural title to which at once becomes full and perfect, the moment possession is taken, provided there be no adverse right. But it is otherwise with respect to government. If the throne, in any country, happens to be vacant, either in consequence of a revolution, or in any other way, the

first occupant, who succeeds in becoming sovereign *de facto*, does not thereby acquire a full title *de jure*, though he has a nascent right. It is impossible for any one to be so far successful without the support of a considerable number of adherents possessed of weight and power; and his ability to conciliate them is in itself a proof of a superior fitness for command. It has frequently been maintained, both in ancient and modern times, that superior natures have a natural right to govern: such persons, it is said, attaining supreme command, "are not so much like men usurping power, as asserting their natural place in society." But at the same time, it must depend upon a variety of considerations that cannot be reduced to rule,—upon the necessity of the case, the individual's fitness for his office, the probability of a successful issue without a disproportioned cost, and in some measure, on his motives,—whether he has, or has not, a right voluntarily to assume the reins of government at all: under such circumstances, the question of right, with respect to him, is not for lawyers, but for moralists and casuists; and it is for individuals themselves to determine, on their own moral responsibility, whether and how far it is their duty to yield obedience, or incur risks and penalties if they withhold it.

142. Passing on from the first origin to the more advanced stages of supreme power, whatever doubts may be entertained respecting its commencement, every day's continuance of it unbroken has a natural tendency to mature it into a full and perfect right. This will be apparent, if we consider the natural effect of time, which is, to improve the relation that subsists between a *de facto* sovereign and his subjects, by obliterating the remembrance of any real or supposed injustice attending his first rise to power, and by begetting and encouraging habits of submission, generous confidence, and loyal attachment towards him on the part of his subjects, sentiments which will enable him to pursue a milder policy than perhaps the object of maintaining his power, in the teeth of distrust and jealousy, permitted at first. The most satisfactory title, then, of sovereign dominion, is that by Prescription. It will be borne in mind how prescription was applied to the right of property, in the last section. Almost every argument and conclusion there offered might be here nearly repeated, with reference to the present subject, by making a few simple alterations, which the reader will be able to do himself. (Nos. 117, 118.) The like may be said with regard to the right of inheritance (No. 117.); as to which, some not very profound thinkers are perplexed to know, why the fact of an individual reigning now, should give his son a title to reign after him. Now the benefit of the public, for which kings reign, is the principle upon which we would wish to rest this as well as every other circumstance connected with sovereign right; and, accordingly, we say, that it is *the subjects'* privilege that the son should succeed to the father; first, because it encourages the latter to govern his kingdom well, in order to transmit it in a flourishing condition to his posterity, and, secondly, because men naturally feel a stronger attachment and respect towards the descendant of an illustrious line of kings, though of but ordinary capacity, than towards an upstart: and this attachment often affords a stronger guarantee of good government on the part of him towards whom it is felt, than even the possession of superior qualities, without it. It is unnecessary, after what has been said in a former page, to defend this feeling from the charge of being a prejudice.

Law.

Progress of the right of government.

Prescriptive right.

Hereditary title.

Law.
Cessation
of the right
of sove-
reignty.

143. As to the mode in which the right of government ceases, reasons similar to those which govern the question between contending proprietors (No. 118.) must decide the just but indeterminate period of time for extinguishing the title of a sovereign *de jure*, unjustly dispossessed, and giving validity to that of an usurper, reigning *de facto*. It would be here superfluous to give those reasons in detail. One important difference, however, must be noticed. The exact period of prescription sufficient for this purpose may be precisely defined by a positive law, in the case of property, but cannot well in the case of sovereign right; because the sovereign himself is the law maker, or at least forms an essential part of the legislature, and it is not likely that he would by anticipation limit the period of his own right as a sovereign; nor indeed would it be safe to contemplate beforehand such a dreadful occurrence as a revolution, which must precede the practical determination of the question. The period of prescription, applicable to such cases, must, therefore, remain for ever in doubt, and be determined by the particular circumstances of each case as it arises. A like doubtfulness must for ever hang over the solution of that "tremendous problem"—What degree of tyranny will justify subjects in rising against their sovereign? The strict maintenance of the relation of sovereign and subject is of the highest importance to man's best interests. Allegiance, therefore, is one of his most sacred natural duties: it must bear up against much provocation from the injustice of a bad ruler. But as human nature is not infallible, as the most exalted station and sacred functions cannot absolutely exempt a man from the possibility of committing the greatest excess of wickedness, there is not strictly, in human nature, any such thing as an absolutely indefeasible right. Sovereign right itself furnishes no exception to this general principle. "There is a limit, at which forbearance ceases to be a virtue." But it is utterly impossible to define the limit. Those who have made the attempt, all come to some vague conclusion, expressive of a case of the most dire necessity, when the very existence of the commonwealth is in jeopardy, when the sovereign has become the *enemy* of his people. The question itself should never be approached or discussed, except with the utmost caution, and in the most guarded terms. The grounds of resistance can never, with propriety or safety, be made an expressed topic in public law; for the aim of every constitution must be to prevent the occurrence of an event requiring such an extreme remedy, rather than to pave the way for it, by laying down rules of procedure, in anticipation of its occurrence.*

Resistance
in extreme
cases of
tyranny.

Functions
of govern-
ment.

144. Having now disposed of the difficult question of the *right* of government, we have next to explain, very briefly, its several functions or powers; which are threefold: the legislative, the judicial, and the executive. These three powers are, in all well-ordered states, kept

distinct, by being vested in the hands of distinct bodies or persons.

145. The functions of the legislature consist in ascertaining and defining, by general rules, the rights and obligations of all the members of the state. The laws or acts of the legislature, made for this purpose, may be regarded as so many standing interpretations of the laws of nature, applicable to the particular circumstances of the community in general, and absolutely imperative upon every member of it.

146. It belongs to the judicial power to interpret and apply the acts of the legislature to every particular case as it arises. It is generally considered to be a matter of importance to narrow the discretion of judges within strict limits. But as legislation is conducted on a *general* survey of what is good for the subjects of the state, and as many minute points must necessarily escape observation before they arise in practice, it follows that a number of subordinate questions, capable of being resolved in a variety of ways, are left for judicial determination; and thus, it is not uncommon for judges to become, in effect, legislators, to a certain extent; that is, where the practice prevails of succeeding judges adopting the decisions of their predecessors, as a general rule, and so giving a permanent authority to such decisions. Bentham is loud and vehement in his vituperation of *judge-made law*; without much reason, we conceive: for though judicial discretion should be restrained within bounds, it neither can nor ought to be altogether prevented; and it is desirable in general that well considered decisions should be afterwards adhered to in like cases. There is, however, one important species of laws, neither judge-made, nor expressly enacted by the legislature, which form a considerable part of the jurisprudence of every country, and become regularly the subjects of judicial cognizance: we mean *customary laws*. A general and long established adherence to an ancient custom is considered as proof of its propriety and binding obligation, for otherwise it would be difficult to account for its extensive and permanent adoption. As it would be superfluous for the legislature to express, by any formal act, the obligation of customs already well known and commonly received, they are properly allowed the same force as express enactments.

147. The executive functions of government may be briefly summed up in the actual administration of force, for whatever purpose it may be required, whether for the execution of the laws, or for the internal or external defence of the realm. Under this head, also, it is usual to include all acts of administration, federal or otherwise, that immediately concern the state in its external relations with other states.

148. In preceding parts of this section, sovereignty was treated generally, as importing a right to direct and control permanently the actions of a multitude of persons forming a community or state. To be now more specific, its essence consists in the possession of supreme *executive* power; from which it follows that a sovereign must also have at least a substantive voice in the legislature, so as to make his consent necessary to every legislative enactment; for otherwise he is but the first subordinate executive officer in the state, under the supreme power of an independent legislative body, which would then in reality be the true sovereign. It is not essential to sovereignty to exercise judicial functions, though it is usual for the sovereign to name the

* Speaking of the English revolution, Sir W. Scott says: "The foreigner who peruses our constitution for the forms of procedure competent in such an event as the Revolution, might as well look in a turnpike Act for directions how to proceed in a case resembling that of Phaeton." *Life of Napoleon*, vol. viii. p. 204. On the general question of resistance, the reader may consult with advantage, Grotius, *De J. B. et P.* lib. i. ch. iv.; Puff., *L. of N. and N.* book vii. ch. viii.; Sir J. Mackintosh, *Hist. of the Rev. in Eng.* in 1688, ch. x.; Burke, *Appeal from the New to the Old Whigs*, Works, vol. vi.

Law.
Forms of
govern-
ment.

judges. The sovereign is the only person in the state legally irresponsible, in all respects.

149. The *form* of government depends chiefly on the form of the legislature. There are three simple forms; viz. a monarchy, an aristocracy, and a republic. In a monarchy, the sole legislative, and consequently, the supreme executive authority, is lodged in the hands of a single individual; in an aristocracy, it is lodged in the hands of a select council; and in a republic, in the hands of a number of persons connected with the mass of the people, commonly by some species of representation more or less extensive. From various combinations and modifications of these simple forms, several kinds of mixed governments may be constructed. It is not our purpose to enter into an examination of their several structures, or a discussion of their relative merits, a discussion, upon which political writers have given free scope to their fancy. Only this is to be observed, that a government, like ours, properly compounded of

all the three simple kinds, is admitted, on all hands, to be the best.

150. We must now conclude this Chapter, which has been extended far beyond its fair limits. In it, we have attended more to the fundamental principles which lie at the root of all legal obligations, and connect law with morals, than to the forms and modes of arranging and giving expression to those obligations. A knowledge of the superstructure of law in general is to be gained from an examination of the principal systems of particular jurisprudence, and especially of the great systems of positive law which may be considered to belong not to any nation in particular, but to the civilized world in general. THE LAW OF NATIONS, though not the first in point of time, considered as a formed and regular system, stands first in the extent and universality of its obligation; and therefore it shall form the subject of the next Chapter.

Law.
Conclusion.

LAW.

CHAPTER II.

THE LAW OF NATIONS.

Law.
Definition
of the law
of nations.

151. THE Law of Nations* is that law by which the relative rights and duties of nations, whether belligerent or neutral, at war or peace, are defined and enforced.

It is not to be confounded with the *Jus Gentium* of the Roman civilians, who by that term intended what has been usually understood and discussed as the law of nature. *Quod naturalis ratio inter omnes homines constituit, id apud omnes peræque custoditur, vocaturque jus gentium.* (D. i. 1, 9.) We have already remarked (45.) that the law of nature, according to the civilians, embraced the whole animal kingdom in its operation; with us the law of nature is, like the *jus gentium*, considered as operating upon mankind alone.

In proceeding to examine the system, we shall discuss (1) its origin, (2) its history, (3) its sources, (4) its authority, (5) its general rules, (6) its sanctions.

Sect. 1. Origin of the Law of Nations.

Opinions
of Hobbes
and Puf-
fendorf;

152. On this subject considerable difference of opinion subsists amongst jurists: Hobbes and Puffendorf† deny that the distinction between the law of nations and the law of nature is otherwise than verbal, and affirm that "what, speaking of the duty of particular men, we call the law of nature, the same we term the law of nations when we apply it to whole states, nations, and people."

of Grotius; Grotius, on the other hand, treats the distinction as real and substantial: "When," he says, "many men of different times and places unanimously affirm the same thing for truth, this ought to be ascribed to a general cause, which in the question whereof we are treating can be no other than a just inference drawn from the principles of nature or a universal consent. The former shows the law of nature,‡ and the latter the law of nations." "That," he adds, "which cannot be deduced from certain principles by just consequence, and yet appears everywhere observed, must owe its origin to a free and arbitrary will." The authority and origin of the law of nations he ascribes to "the will of all, or, at least, many nations;" its proofs, he affirms, to be "the same as those of the unwritten civil law, viz., continual use and the testimony of men skilled in the law."§ Vattel,

and of
Vattel.

* Dr. Zouch, an eminent English civilian, has suggested the title *Jus inter Gentes*, or, as we translate it, international law, as more appropriate; and the suggestion has been adopted by the Chancellor D'Aguesseau, Mr. Bentham, and Dr. Wheaton, the author of the latest, and in some respects the most useful work on the subject. Doubting, however, with Sir James Mackintosh, "whether innovations in the terms of science always repay us by their superior precision for the uncertainty and confusion which the change occasions," we have thought it preferable to retain the name by which this system is best known.

† Hobbes, *De Cive*, ch. xiv.; Puff. *Law of Nature and Nations*, ii. iii. xxiii.

‡ *De J. B. et P.* prel. xli.

§ *Omni in re consensio omnium gentium lex naturæ putanda est.* Cicero, *Tusc. Quæst.* lib. i. cap. xiii.

perhaps the most popular writer on the subject, seeks to reconcile these discordant opinions. He observes* that "the application of a rule cannot be reasonable or just unless it is made in a manner suitable to the subject. We are not to believe that the law of nations is precisely and in every case the same as the law of nature, the subjects of them only excepted, so that we have only to substitute nations for individuals. A civil society or state is a subject very different from an individual of the human race, whence, in many cases, there follows, in virtue of the law of nature itself, very different obligations; for the same general rule applied to two subjects cannot produce exactly the same decision when the subjects are different, since a particular rule, which is very just with respect to one subject, may not be applicable to another. There are many cases, then, in which the law of nature does not determine between state and state, as it would between man and man. We must therefore know how to accommodate the application of it to different subjects; and it is the art of applying it with a justice founded on right reason that renders the law of nations a distinct science."

153. In proceeding to examine the position so broadly laid down by Hobbes, we find that he bases it on an assumption which is altogether at variance with truth, and which he states thus: nations, when once instituted, become endued with the personal properties of individuals, and are therefore, like individuals, subject to the law of nature. This fashion of considering states as beings possessed of the qualities and capacities of individuals, and, consequently, subject to the same general law, is gravely vindicated by Sir James Mackintosh,† who observes that, so to consider them, is no "fiction of law," but "a bold metaphor," and pregnant with the useful moral, that states in their dealings with each other should respect those great principles of justice which avowedly ought to regulate the intercourse of individuals. The metaphor is bold, and may carry a moral, but most assuredly metaphors form no safe foundation for reasonings, and, if we may credit history, have in every age served only to perplex and obscure the researches of the philosophical inquirer.

Plainly to speak, we may safely affirm that states differ from individuals in every quality in virtue of which individuals are subject to the natural law. A state is a metaphysical entity, a mere abstraction, a general term which convenience has dictated to express the combined action of a number of individuals. Thus where a war is declared by the sovereign of one state against the sovereign of another state, it implies that the whole nation

What a
state is.

* *Droit des Gens*, prel.

† *Discourse*, p. 7. *Nescio quo modo nihil tam absurde dici potest, quod non dicatur ab aliquo philosophorum.* Cicero, *De Divin.* lib. ii.

Law.

declares war. "Every man," says Chancellor Kent, "is in judgment of law a party to the acts of his own government; and a war between the governments of two nations is a war between all the individuals of the one and all the individuals of which the other nation is composed." 1 *Comm.* 55. A state has no conscience, no capacity of suffering, no mortal attributes whatever.

The members of a state (that is, those whose union constitutes the state) are, in their capacity of individuals, of course, subject to the natural law. From the operation of this law their quality of citizenship, which subjects them also to the authority of a municipal law, exempts them in no degree; and this natural law regulates their conduct in all possible conditions and relations of life, as sovereigns and as subjects, and in their transactions with the sovereign and with the subjects of their own or any foreign state. The authority of the law of nature is in fact co-extensive with mankind.

The law of nations distinct from the law of nature.

154. The law of nations is, however, very distinct in its character; its rules are not the same, its sanctions are wholly unlike, its obligation is limited. As is every system of law, it is of course based on the principles of the law of nature; but these, if it defines, it modifies and enforces with its own peculiar sanctions. Indeed, writing not of ethics but of law, of *what is* and not *what ought to be*, we must acknowledge, that so far from the law of nations being identical with the law of nature, the former confessedly permits, regulates, sanctions, and approves of transactions wholly repugnant to the sovereign and fundamental principles of the latter. An instance of this will at once suggest itself to the mind of the reader in any degree familiar with the history of modern diplomacy. In an elaborate and most masterly judgment of the supreme court of the United States of America, the slave trade is admitted to be "contrary to the law of nature." Still in this trade for a long series of years the principal and most enlightened nations of Europe have been engaged; the trade then was sanctioned by their usage, and, with such a sanction, could not be pronounced contrary to international law. The fact that some of these nations have lately forbidden the pursuit of this traffic to their subjects, and have entered into treaties with one another for the abolition of the commerce, would not operate so as to render it unlawful as far as the subjects of other states were concerned. The municipal regulations of no state can operate upon foreigners beyond its frontiers, nor can the special arrangements of any two or more states limit the independent rights of the others.*

The language of Sir William Scott, in reference to the same subject, was similar.† This great judge has well expounded the relations which subsist between the two systems, the law of nations and the law of nature. "A great part of the law of nations," he says, "stands on the usage and practice of nations, and on no other foundation: it is *introduced*, indeed, by general principles, but it travels with these principles only to a certain extent, and, if it stop there, you are not at liberty to go further, and to say that more general speculations would bear you out in a further progress; thus, for instance, on mere general principles, it is lawful to destroy your enemy, and mere general principles would make no great difference as to the manner in which this was effected, but the conventional law of mankind, which is evidenced in

their practice, does make a distinction, and allows some and prohibits other modes of destruction, and a belligerent is bound to confine himself to those modes which the common practice of mankind has employed."*

155. The law of nations originates in the will of nations; its authority is their consent, and its evidence is their practice and conventions. Practice evidences what is called the *customary* law of nations, and conventions the *conventional* law of nations.

Law.

Origin and evidence of the law of nations. Its divisions.

(1.) The larger proportion of the law of nations owes its origin to the practice and usages of nations. Custom is a prolific source of municipal jurisprudence, and Lord Erskine used to affirm, somewhat rashly it is true, that "there is no other law in England than custom."† The obvious conveniences of certain rules has obtained for them, in the intercourse of civilized communities, an acceptance and consequent authority inferior in no degree to that which attaches to the results of express compact and solemn convention. In so far as this acceptance extends, so far extends the operation of the rules thus recognized. Some of these rules are partial in their operation, because the usages which have originated and evidence them are only local in their nature, such, for instance, as is the case with the customary law relating to the whale fishery.‡

It is competent for any nation, that so pleases it, to renounce any of her customs, and so to exempt herself from the jurisdiction of such portions of the law of nations as those customs warrant. A timely notice of her intention so to do has usually been esteemed proper on the part of the state.§

(2.) The conventional law of nations is recorded in the treaties to which at different times the various independent powers have become parties. These are considered to have an operation beyond the contracting parties. The circumstance that they are for the most part constructed in reference to the same principles and by diplomatists educated in the same school of public law, and referring as authorities to the same writers, has given them an authority in the resolution of vexed questions, and in the exposition of what the law actually is upon any point which may have been doubted.||

Having thus explained the origin of the law of nations, we proceed to trace its history.

Sect. 2. History of the Law of Nations.

156. The Law of Nations is the natural result of a state of comparative civilization, in which the benefits of commerce and international intercourse are known and appreciated. By the Greeks every foreigner was esteemed a barbarian, and barbarian and enemy were synonymous terms; without an express compact, men in their belief owed no duties to each other, and we may reasonably refer the indignation expressed by the Ithacans against Eupheithes for having joined the plundering Taphians against the Thesprotians, to the fact of a

Law. league subsisting between themselves and the latter nation. There is much force in the expression—

*οἱ δ' ἡμῶν ἄρθροισι ἦσαν.**

Greek public law.

Subsequently the mutual relations of Grecian states were subjected in some degree to regulations which, being religious in their character, were enforced by the *βουλή* or council of the Amphyctionic league, itself a religious institution. The public law to which we refer may, according to M. Sainte Croix, be reduced to the following principles:—(1) those who perished in battle were to be buried; (2) no permanent trophy was to be raised in commemoration of a victory; (3) the lives of such as take refuge in the temples of a captured city were to be spared; (4) burial was to be denied to the sacrilegious criminal; (5) no molestation was to be offered to the Greek resorting to the public games and temples and there sacrificing.† The Amphyctionic league itself was, however, a party to the most cruel and oppressive acts when the interests of its favourite Delphians were in question. Witness its conduct in the first Sacred War, when at its instigation the Athenians, by an artifice of Solon, succeeded in poisoning the Crisseans, and levelling their city with the ground.‡

Amongst the Romans.

157. The Romans appear to have made but little advances towards recognizing an international law, although of such a system Cicero conceived the necessity, and advocated the adoption, whilst his great rival, Sallust, did not hesitate to denounce a Numidian massacre, by Marius, as *contra jus belli*. These facts, with the circumstance that the Romans established a college of heralds, and instituted a fetial law, have led writers to infer that amongst this people subsisted just notions of the relative duties of states; but an examination of their history will show the supposition to be erroneous. Some formalities§ were certainly adopted in the declaration of hostilities, unknown as it would appear to the Greeks; the relation of allies was recognized in principle, however neglected in practice, but the moderation towards the vanquished, certain fruits of international law, ascribed by the patriotism of Seneca and Tacitus to the founder of Rome, was, in fact, no more than the policy of an infant state anxious to increase its strength by the incorporation of conquered enemies, and was found no ways incompatible with the Roman victor dragging at the chariot wheels of his triumph the kings and senates whose captivity he had purchased with his sword. With the fetial law we are only imperfectly acquainted, but it seems to have been simply a law peculiar to the Romans, and regulating their conduct towards foreigners, and not properly an international law common to other nations, and determining on general principles their respective rights and duties.

Roman Fetial law.

International law of the Middle Ages.

158. If the middle ages were distinguished by a larger appreciation of the rights of nations, and an approach to the true principles of a law of nations, it is owing chiefly to the diffusion of Christianity through Europe. According to Barrington,|| merchant strangers were by the laws of the Wisigoths not only protected, but permitted to enjoy the benefit of their own laws. In Sicily the plunder of shipwrecked goods was made a capital offence; whilst the Bavarians assured safety and immunity to all foreigners entering their territories. Our

Magna Charta also (cap. xxx.) extended protection and offered encouragement to merchant strangers. The extension of commerce* and the rise of a spirit of community in Europe, to which the Crusades and the system of chivalry gave birth, originated by degrees the rudiments of an European public law and treaties, formal declarations of war, and a more general recognition of the rights of ambassadors were all so many evidences of the march of civilization. This public law, or law of nations, to the development of which contributed, in a great degree, the study of the Roman jurisprudence, was considered as operating only upon Christian nations; and the Pagan and his possessions were still considered the lawful prey of the Christian conqueror. The Roman church, to whom this perversion of Christian doctrine is fairly attributable, was, however, an important agent in the establishment of a law of nations in Europe; and this not simply by the impetus which it communicated to European civilization, but also by constituting a species of European social system of which it became the head. It is difficult to overrate the importance of such a central power which, being independent and antiphysical, and owing its existence wholly to moral influences, was able and disposed to become the arbiter of national differences.

Law.

The Roman church an agent in establishing a law of nations.

159. The perfection of the law of nations has been owing chiefly to two causes: First, to the formation of the political system of modern Europe; and, secondly, to the writings of Grotius and other eminent publicists.

Causes of the perfection of the law of nations.

160. (I.) The political system of modern Europe originating in the relations that have arisen amongst European states is referred by Heeren† generally to the progress of civilization, which necessarily multiplies the points of contact between neighbouring states, and specially to four causes: (1) the Italian wars; (2) the affairs of religion after the Reformation; (3) the necessity of opposing the Turks; (4) the commerce of the colonies, and the commercial interests resulting therefrom. To which he properly adds (5) the facility of communication which printing and the establishment of posts afford. Another bond of union amongst European nations was the similarity of their laws and habits

The political system of modern Europe.

* Some notice must be taken of the maritime codes which contributed greatly to develop the elements of international law in Europe. The Rhodians—a people to the extent of whose commerce and power Cicero, who studied amongst them, bears testimony (*Orat. pro Leg. Manil. xviii.*)—possessed a code of this kind, which was recognized at Athens, in all the islands of the Ægean, and throughout the coasts of the Mediterranean. The Roman emperors professed to embody this code in their jurisprudence. It was, perhaps, the foundation of the famous *II Consolato del Mare*; the merit of compiling which has been contested by Pisa, Venice, and Barcelona, and which was first published in the Catalan dialect in the latter place in 1494. Although the jurists of the latter city may have conferred on this code the form in which it is known to us, it is probable to have emanated in the first instance from Pisa. Its antiquity is probably not much earlier than the middle of the thirteenth century. By it were defined the mutual rights of neutral and belligerent vessels; and so far is international law indebted to its framers. Its authority was formally recognized by the King of France and the Count of Provence, and its operation extended to all the Mediterranean states. Regulations borrowed from this source, and which were compiled in France under the reign of Louis IX., were recognized in this country. Known as the laws of Oleron, it has been supposed that we owe them to the wisdom of Richard I. In addition to these, we may mention the ordinances of Wisburg, a town in the island of Gothland, chiefly compiled from those of Oleron, just before 1400: by these the Baltic traders were governed. Hallam, *Middle Ages*, ch. ix. part ii. vol. iii. pp. 396-8.

Law arising from their common origin. It may finally be observed that, as the power of the Roman church declined, the Germanic empire became the centre of the European system, to the solidity and compactness of which it greatly contributed. This end was secured, moreover, by the circumstance that monarchy was the prevailing form of government in Europe, and the direction of public affairs being entrusted to the hands of a few, greater steadiness of international policy was secured than was compatible with the character of democratic institutions.

161. (II.) The second cause of the perfection of the law of nations is owing to the writers on the subject. Some of the principal of these we propose here to enumerate.

Francisco a Victoria. 162. Francisco a Victoria, a Salamanca professor, who commenced teaching at Valladolid in 1525 (reputed the restorer of theological learning in Spain), discusses, in his *Relectiones Theologicæ* (Lyons, 1557), the general right of war: the difference between public war and reprisals; the just and unjust causes of war; its proper ends, and the right of subjects to examine its grounds. He bases the rights of the king of Spain over the American Indians on the ground (*inter alia*) that the Indians had denied permission to trade in their country, which he esteems a just cause of war, but denies that the war was just simply because the Indians were Pagans.

Dominic Soto. 163. The next writer on this branch of jurisprudence claiming a passing remark is a pupil of Victoria, Dominic Soto, a Spanish Dominican, distinguished for the active part he took in the Council of Trent against both the Papal and Scotist factions. He was consulted by the Emperor Charles V., to whom he was confessor, on occasion of a conference held before him at Valladolid, in 1542, at which Sepulveda appeared as the champion for the Spanish colonists and Las Casas as an advocate for the oppressed American Indians. The opinion of Soto was conformable to that of his great master,—“*Neque discrepantia (ut reor) est inter Christianos et infideles, quoniam jus gentium cunctis gentibus æquale est.*” His celebrated work, *De Justitia et Jure*, from which this passage is taken, was published in 1568. Soto condemned in strenuous language the disgraceful atrocities of the slave trade.

Balthazar Ayala. 164. Probably the earliest work in which the practice of nations in time of war is to be found fully discussed is one by Balthazar Ayala, judge advocate (if we may so use the term) to the Spanish army in the Netherlands, under the command of the Prince of Parma. It is entitled *De Jure et Officiis Bellicis et Disciplinâ Militari*, lib. iii.; was published about 1582; and was highly commended by Grotius. Like Victoria and Soto, the author denies the lawfulness of levying war against infidels, even by the authority of the Pope, on account of their religion, for their infidelity does not deprive them of the right of dominion, inasmuch as the sovereignty of the earth was given to every reasonable creature. “*Et hæc sententia*,” he adds, “*plerisque probatur, ut ostendit Covarruvias.*”

Albericus Gentilis. 165. Albericus Gentilis, the next international jurist of note, was an Italian protestant, who, through the Earl of Leicester, obtained the professorship of civil law at Oxford. His work *De Legationibus* was first published in 1583, and another by him, *De Jure Belli* (Lyons, 1589), was imitated in its plan by Grotius in the first and third books of his great work.

We may also mention the name of the renowned jesuit, Francisco Suarez, the casuist, who flourished in

the latter part of the sixteenth century, and who by his treatise, *De Legibus ac Deo Legislatore*, proves that he was the first to see, according to Sir James Mackintosh, “that international law was composed not only of the simple principles of justice applied to the simple intercourse between states, but of those usages long observed in that intercourse by the European race which have since been more exactly distinguished as the consuetudinary law acknowledged by the Christian nations of Europe and America.”*

Law.
Francisco
Suarez.

166. Of Grotius, and some of his more distinguished successors, we have already (Ch. I.) spoken. We cannot, however, pass over the name of Samuel Puffendorf, who (born in 1681) was chosen by Charles Lewis, the Elector Palatine, to fill the chair of Law of Nature and Nations at Heidelberg, the first chair of the kind instituted in Europe. His *De Jure Naturæ et Gentium* first appeared in 1672, and is a highly valuable work. The author was styled by Leibnitz *Vir parum jurisconsultus et minime philosophus*.

Samuel
Puffendorf.

167. Subsequently to this time have flourished the translator and editor of Grotius, Puffendorf, and Bynkershoek, Jean Barbeyrac, who translated Grotius into French, with notes, in the year 1724, Puffendorf (the best edition of which is that of London, 1740), and Bynkershoek. He added valuable notes to all his translations. Christian de Wolf (born 1679) was professor at Halle, 1707, and at Marbourg, 1723 to 1754. His *Jus Gentium* was published at Halle in 1749. Bynkershoek, a jurist of Holland, is a useful and learned writer of authority. His *De Dominio Maris* was published in 1702; his *De Foro Legatorum* in 1721. His principal work, *Quæstiones Juris Publici*, has been translated into French by Barbeyrac (Hague, 1724), and into English by that learned jurist, Dr. Du Ponceau, provost of the law academy of Philadelphia. Both of these editors have added valuable notes. Professor Von Martens is a distinguished jurist; and we may fairly add the name of a living writer, Dr. Henry Wheaton, long a reporter of the Supreme Court of the United States of America, a Scandinavian antiquary of no mean reputation, and who has filled, with credit to himself and with advantage to his government, the post of resident minister at the court of Berlin. His *Elements of International Law* was published in London in 1836. We ought not to omit all mention of Sir James Mackintosh, whose devotion to public life alone prevented him from acquiring high reputation as a philosophical and highly accomplished jurist.

beyrac.

Sect. 3. Sources of the Law of Nations.

167. The Law of Nations, according to Sir William Scott, is “fixed and evidenced by general, ancient, and admitted practice, by treaties, and by the general tenor of the laws, ordinances, and formal transactions of civilized states.”† It does not enjoy the advantage possessed by every system of municipal jurisprudence, of being expounded and enforced by an independent and impartial judiciary; and if in some points it should be deficient in that precision and certainty which, taught by one of his great oracles, the English lawyer is prone to esteem the highest perfection of every jurisprudential system,‡

Sources.

‡ “Certainty,” says Lord Hardwicke, “is the mother of repose, and therefore the law aims at certainty.” *Walter v. Tryon*, 1 Dickens, 245.

Law.

1. Text-writers.

it is chiefly owing to this fact. The sources of the law of nations may be enumerated as follows:—

169. (1.) Text-writers of authority, an authority which they obtain whenever they record the usages and practice of nations, and whenever their speculations are conceived in a spirit of impartiality. This is a character which especially belongs to the great work of Grotius, and is consistent with the disposition of one whose candour and love of justice so far subdued his personal feelings as to enable him rightly to appreciate the character of his inveterate persecutor.* The writings of Puffendorf and the other publicists already mentioned have always been considered as forming a part of the *corpus* of international law. The degree of authority to which the writings of certain publicists is entitled will always be a subject of controversy. Such, for instance, as that of Selden, who in his work, *Mare Clausum* (1635), following in the steps of Alberic Gentili (*Advocatio Hispanica*, 1613), asserts the right of England to the sovereignty of the British seas. But generally it is to the works of jurists that the nations of Europe appeal as authorities in the determination of their mutual differences. Our own country has been distinguished by the deference she has on all occasions paid to these venerable and enlightened expositors of international jurisprudence.†

2. Decisions of international tribunals and courts of prize.

170. (2.) The adjudications of international tribunals as boards of arbitration and courts of prizes. The degree in which the authority of these adjudications is admitted depends of course in a great measure on the constitution of the tribunals from which they emanate. "Greater weight," says Mr. Wheaton, "is justly attributable to the judgments of the mixed tribunals appointed by the joint consent of the two nations between whom they are to decide, than to those of Admiralty courts established by and dependent on the instructions of one nation alone."‡

3. Ordinances of states.

171. (3.) Ordinances of particular states prescribing rules for the conduct of their commissioned cruisers and prize tribunals.§

4. Histories.

172. (4.) The history of all diplomatic transactions.

5. Treaties.

173. (5.) Treaties, whether of peace, alliance, or commerce.||

Sect. 4. Authority of the Law of Nations.

Subjects of the law of nations.

174. The subjects of the law of nations are what are usually designated *sovereign* states; that is, states which govern themselves independently of foreign powers. It is not necessary in this place to enter into any lengthened description of the signs and tokens in which this quality of sovereignty manifests itself. The right of negotiation is, as far as the law of nations is concerned, the

most important of these; and this is a right which may be modified by compact without the state forfeiting its title to be considered as a sovereign state. Such is the case with the states which form the Germanic Confederation, who, by the terms of their union, are precluded from negotiating a separate treaty, or even concluding an armistice, without the consent of the Confederation, with any power against whom the Confederation have declared war.* On the other hand, in the Swiss Confederation, while the Diet possesses the exclusive right of declaring war and effecting treaties, each canton is authorized to conclude for itself military capitulations and treaties relating to economical matters and matters of police, so long as they do nothing inconsistent with the federal part and with the rights of the other cantons. By the constitution of the United States of America, no state is permitted "to enter into any treaty, alliance, or confederation by itself, keep troops or ships of war in time of peace, enter into any agreement or compact with a foreign power, or engage in war, unless actually invaded or in such imminent danger as will admit of no delay."† The president has power, by the consent of the senate, provided two-thirds of the senators present concur, to levy war, make peace, and enter into treaties.‡ The right of negotiation, apart from compact, depends upon the internal organization of the state, and of this, to use an expression familiar to municipal jurisprudence, every other state is bound to take notice.

175. The authority of the law of nations, owing its existence to the will of nations, is necessarily limited to those nations that have evinced their willingness to be bound by it. To learn what nations have done so we must resort to history for information; but speaking generally, we may say that, as a system, it has been adopted by, and therefore binds, all the nations of Europe§ and their emancipated colonies in the other hemisphere. Formerly it would seem to have been doubted how far the Turkish empire could have been considered within its range;|| but modern events teach us to consider that power as a member, and no unimportant member, of the European commonwealth, and as clearly subject to the law of nations. As to those nations whose policy forbids our considering them in the same light, we may conclude that they are entitled to the protection of international law no further than what an enlightened appreciation of the natural rights of states will obtain for them. To treat these nations with cruelty—to violate their independence—to oppress their citizens—to despoil their dominions—these are acts so plainly inconsistent with the character of civilized nations—so wholly repugnant to the obvious dictates of natural justice, that the state who indulged in them would draw down on itself the just indignation of Europe; but at the

Law.

Right of negotiation.

Limits of the authority of the law of nations. European nations and their emancipated colonies. Turkey.

* Prince Maurice of Nassau. Gustavus Adolphus, during the war he undertook to secure the liberties of Protestant Europe, always slept with the Treatise of Grotius under his pillow. It was the study of Lord Bacon's writings, we are told by Barbeyrac, that first suggested to Grotius the idea of reducing the law of nations to a science. *Notes to Puffendorf*, sec. 2.

† See the report made to the king in 1753, in answer to the Prussian memorial, prepared by Sir George Lee, Dr. Paul, Sir Dudley Ryder, and Mr. Murray (Lord Mansfield). Smollett's *Hist. Eng.* ii. 301. Amongst the writers quoted in our courts are Barbeyrac, Vattel, Wicquefort (*Viveash v. Becker*, 3 Maule & S. 284), Bynkershoek, Grotius, and Puffendorf (*Wolf v. Oxholm*, 6 Maule & S. 192).

§ The law of nations is adopted in Great Britain in its full and most liberal extent by the common law, and is held to be part of the law of the land; and all statutes relating to foreign affairs should be framed with reference to that rule. 4 *Comm.* 67; *Ricord v. Bettenham*, W. Bl. Rep. 564; *Triquet v. Bath*, W. Bl. Rep. 471; *Hopkins v. De Robeck*, 3 Durnf. & East, 79; *Viveash v. Becker*, 3 Maule & S. 284.

|| Martens, *Précis*, *Introd.* sec. 4. It observed, however, according to this writer, none of the forms of diplomatic etiquette, liv. vii. c. vi. sec. 1. See also 1 Wheaton, 221, and Co. *Inst.* 155; Klüber, *Droit des Gens Mod. de l'Europe* 2. 1, ch. ii. sec. 5.

Law. same time these uncivilized states are not entitled to those formal courtesies or privileges which the comity of civilized nations consider as naturally due. Instances of the kind alluded to are such as respect the ransom of prisoners of war, the rights of ambassadors, &c.* They cannot expect to receive advantages which they deny to others.

Thus a formal sentence of condemnation by a court of admiralty was not considered requisite to transfer the property in a vessel captured by the Algerines, and subsequently sold *bonâ fide* to a Christian purchaser. It was held sufficient if the confiscation had taken place by a public act of the competent authority, according to the custom established in that part of the world.† This was the distinction between them and more civilized states. The African states were not, however, deemed as exempt from an observance of the law of blockade, and this for good and sufficient reasons. "On a point like this," said Sir William Scott, "the breach of a blockade—one of the most universal and simple operations of war in all ages and countries, except such as are merely savage—no indulgence can be shown. It must not be considered by them that if an European army or fleet is blockading a town or port that they are at liberty to trade with that port. If that could be maintained, it would render the obligation of a blockade perfectly nugatory. They, in common with all other nations, must be subject to this first and elementary principle of blockade,—that persons are not to carry into the port supplies of any kind. It is not a new operation of war; it is almost as old and general as war itself. The subjects of the Barbary States could not be ignorant of the general rules applying to a blockaded port so far as concerns the interests and duties of neutrals."‡

Indian states and Morocco. 176. The native princes of India appear also to have been considered as within the operation of the general principles of the law of nations;§ and, as it would seem by a case decided in the reign of Queen Elizabeth, the Emperor of Morocco also.||

177. In the earlier periods of European history, the rights of every Christian people to subject savage nations to their dominion, and to dispossess them of their territories, were not only vindicated in theory but asserted in practice. The popes, who considered themselves as lords paramount of the princes, were accustomed to secure the support and reward the fidelity of their royal subjects by ample donations of territory "*in partibus infidelium*." Thus did Alexander VI., in 1493, bestow on Ferdinand and Isabella of Spain the lands not previously occupied by a Christian nation, discovered and to be discovered beyond a line drawn from pole to pole one hundred miles west of the Azores; and thus did Nicholas V. confer the sovereignty of Guinea, and the

right of subduing its inhabitants, on Alphonso of Portugal and the Infant Henry.* The sovereigns thus favoured did not, it would seem, consider it altogether prudent to rest their title to their new acquisitions on these grants. The rights of discovery and of priority of occupation were frequently alleged by them. The lawfulness of spoiling the idolator is assumed in the patent granted by Henry VII. of England to the celebrated John Cabot (Giovanni Gavottæ) and his sons, who are thereby empowered "to seek out and discover all islands, regions, and provinces whatsoever that may belong to heathens and infidels," and "to subdue, occupy, and possess these countries as his vassals and lieutenants." Sir Humphrey Gilbert was authorized by Queen Elizabeth "to discover such remote heathen and barbarous lands, countries, and territories not actually possessed of a Christian prince or people, and to hold, occupy, and enjoy the same, with all their commodities, jurisdictions, and royalties."

Sect. 5. General Rules of the Law of Nations.

178. Before proceeding to state those principles to which the Law of Nations appears most readily reducible, it is desirable that some consideration should be given to two circumstances which jurists do not appear to have sufficiently attended to, and their neglect of which has, in many instances, deprived their speculations of that practical value which otherwise would have belonged to them. This neglect appears to have resulted from an imperfect appreciation of the true character and scope of the law of nations.

179. In the first place, it may be remarked that this system of jurisprudence in so many points approximates to the science of general politics, that it is difficult to ascertain its appropriate boundaries. By the science of general politics—a term tolerably intelligible, though assuredly not very precise or determinate—we would be understood to mean the science of civil prudence, or, as Lord Bacon styles it, civil knowledge; and which belongs to the province of ethics rather than of law. This science, being "conversant about a subject which of all others is most immersed in matter and hardliest reduced to axiom,"† is beset with so many difficulties of its own, that to confound it with the law of nations is only to perplex and impede the resolution of questions properly distinct in their character, and in themselves sufficiently complicated and embarrassing. States, it must be remembered, may not always enforce their just claims‡—privileges may be waived—positive injustice may be endured; at times things lawful may not be thought convenient; and on all occasions we cannot safely argue from the fact to the right, and conclude from what is done, what ought to have been done. With examples illustrative of this, the diplomatic history of Europe is

* 1 Wheaton, *Elem.* 52.

† The "*Helena*," 4 Robinson, *Rep.* 3. Formerly it was considered that there was no change of property in case of a recapture so as to bar an original owner in favour of a recaptor or his vendee until there had been a sentence of condemnation. (*Goss v. Withers*, 2 Burr. *Rep.* 696; *Lindo v. Rodney* and another, 2 Douglas, *Rep.* 616; the "*Flad Oyen*," 1 Robinson, *Rep.* 139.) See also 13 Geo. II. c. 4, and 29 Geo. II. c. 34.

|| 4 Co. *Inst.* 152-4.

* 1 Wheaton, *Elem.* 209; Vattel, liv. i. ch. xviii. sec. 208.

† *Advancement of Learning*, p. 272; edit. 1633.

‡ Martens, *Précis*, liv. ii. ch. iii. sec. 1. As an instance of this we may refer to the reply of the British government (25 Sept. 1807) to the Russian declaration of war in 1807. This latter power insisted on the proceedings of the British fleet in entering the Sound and attacking the Danish capital, in disregard of the inviolability of the Baltic. In answer, the principles on which the inviolability of that sea had been rested were denied, although it was admitted that our government had at particular periods, for special reasons, forborne to act in contradiction to them. *Papers laid before Parliament*, January, 1808. On such doubtful questions, see some observations by Mr. Wheaton. 1 *Elem.* 96-7.

Law. rife; and there is nothing that the jurist ought more sedulously to avoid than ascribing a scientific value to what is the result simply of prudent policy—a policy which has regard less to positive rights than to times and occasions.

Distinction between international and public law. 180. In the second place, jurists have not sufficiently apprehended the true province of the law of nations which is conversant solely with the *mutual* relations of nations, and which is distinct from that public law* by which the internal organization of states and the rights and duties consequent thereon are defined and enforced. When Vattel wrote “of nations considered in reference to themselves,”† described the constitutions of various communities, and eloquently disserted on “the objects of a good government,”‡ he occupied himself with a subject distinct from “the Law of Nations.” A similar confusion of ideas is visible in the *Manual* of Mr. Wheaton. A charge so serious against a writer of such high reputation must not be hazarded without proof. Every state possesses, by the very terms of its existence, certain rights. These are incidental to its very character as a state. They arose antecedently to the law of nations, and subsist independently of it. They are recognized by the law of nations, which, indeed, for their very security, subjects them to certain modifications in practice. Such are the undoubted rights of every state to its security—its independence—its equality, and its property. In terming them the “absolute international rights of states,”§ Mr. Wheaton employs an improper term, for though these rights are guaranteed by international law, they cannot be called international rights, for their existence was prior to international law.

181. They are the rights of states *as states*; they result from the law of nature, and not from the law of nations; and to characterize them, as has been done by Mr. Wheaton, can only serve to perpetuate the confusion apparent in the writings of so many jurists who have been unable to distinguish the frontiers of natural and international law.

We proceed to show how the law of nations deals with these rights, and to exhibit the modifications to which it subjects them.

Right of security. 182. (I.) *The Right of Security*.—It is the undoubted duty of every state to protect its subjects from foreign aggression in the lawful exercise of their industry and the enjoyment of their property. Bound by this duty, every state, on general principles, is entitled to raise armies, build fortresses, and levy taxes which may furnish a revenue efficient for these purposes.

183. By convention, this right may be, and often is, limited. Thus, by a treaty with France, in 1685, the Genoese republic agreed to disarm a portion of its navy.|| By the treaty of Aix-la-Chapelle (1748), and of Paris (1786), the French agreed to destroy the fortifications of Dunkirk, so long the terror of our Channel trade; while, by the treaty of 1815, they covenanted to demolish the fortifications of Huningen, which for many years had menaced the city of Basle, and stipulated to raise none others within three leagues of that city. These may be thought the hard terms which the power of the conqueror enabled him to impose in the insolence

Law. of victory, but they were justified on the ground that they were requisite to the preservation of that very principle—the right of security—which they appeared at first sight to contravene.

184. It was long a moot question amongst jurists how far an interference is justified when a state already powerful is increasing her power to such an extent as to become an object of terror to her neighbours.* It is the unquestionable right of every state to multiply its resources, as well by internal improvement as by external aggrandizement, provided it does not violate the rights of other states. “Nevertheless,” says Professor Martens, “it may so happen that the aggrandizement of a state already powerful, and the preponderance arising from it, may sooner or later endanger the safety and liberty of the neighbouring states. In such case there arises a collision of rights, which authorizes the latter to oppose by alliances, and even by force of arms, so dangerous an aggrandizement, without the least regard to its lawfulness.”† Grotius, on the other hand, denies that “the dread of our neighbour’s increasing strength is a warrantable ground for our taking up arms against him;”‡ and with him Vattel§ concurs. The wars undertaken for the preservation of that famous system, known, from its operation, as *the balance of power*, naturally suggested this question. It is one on which no doubt can reasonably be entertained at this day. We have no right to interfere with a neighbour who is enlarging his dominions by colonization, or strengthening his frontier with fortifications, unless we have good reason to apprehend that he is meditating aggressions on us. If we have reason to suspect that his intentions are hostile, we shall naturally place ourselves in a posture of defence; but assuredly the naked fact that he is increasing his power, and by means in themselves perfectly legitimate, will give no title for our interference.

185. (II.) *The Right of Independence*.—This is a right which belongs to every sovereign state as such, and one especially tendered and protected by the law of nations. No nation, unless authorized thereto by compact, is entitled to interfere in the internal concerns of another, whether those concerns relate to government, legislation, or the administration of justice. Compact, indeed, in some cases modifies this right. In pursuance of treaties to that effect, the kings of Denmark were empowered to arbitrate in any differences that might arise between the kings of Sweden and their senates; and the kings of Sweden had similar authority in cases of disputes in the Danish government. The princes and states of West Friesland in like manner agreed to submit to the decision of the republic of the United Provinces matters on which they were divided; and many other cases of a similar kind might be mentioned.¶ A title of interference may also ensue treaties of mediation and guarantee. Thus, France and Sweden, at the peace of Westphalia, in 1648, guaranteed the Germanic constitution on the basis on which it was then settled; and the present constitution of the Helvetic Confederation was adjusted by the mediation of the allies, in 1813. So also may the constitution of any of the states composing the Germanic Confederation be guaranteed by the Diet, on the application of the state: the Diet then acquires a right

Law.

to determine the construction and enforce the maintenance of the constitution so guaranteed.* It is usual when intestine divisions vex a state, for those states with whom it is in amity to proffer their mediation of any intestine divisions which may distract any member of the great European commonwealth; and the acceptance of such an offer by both parties gives to the state offering the right to interfere.

The Holy Alliance.

186. There are other circumstances under which this right originates; and modern history has recorded the establishment of a league (at Vienna, in 1815), well known as the Holy Alliance, whose object was to check the progress of revolutionary principles and to sustain the menaced monarchical institutions of Europe. The justification of such an association is to be found in the peculiar circumstances of the times, which rendered it a measure of absolute necessity on the part of states not prepared to surrender their freedom of action. The considerations which govern the policy of the British government in such matters may be learnt from a declaration of the court of St. James's, issued in consequence of the steps taken by Austria, Russia, and Prussia, in consequence of the Neapolitan revolution of 1820.

Policy of Great Britain.

These were steps which the government of Great Britain esteemed inconsistent with the undoubted right of every nation, as far as its neighbours were concerned, to establish what constitution was agreeable to its wishes. Great Britain, on that occasion, admitted the right of interference so far as a regard to the independence of other states made an interference necessary, but still it regarded the assumption of such a right as only to be justified by the strongest necessity, and to be limited and regulated thereby. The exercise of such a right it considered as an exception to general principles of the greatest value and importance, and as one that properly grows out of the special circumstances of the case, but at the same time considered that exceptions of this description can never, without the utmost danger, be so far reduced to rule as to be incorporated into the ordinary diplomacy of states or into the institutes of the law of nations.†

French invasion of Spain in 1822.

187. The intervention of France with the affairs of Spain in 1822, which led to the overthrow of the Spanish constitution, was also protested against on similar grounds by the British government. It declared the original alliance between Great Britain and the other powers to have been "an union for the reconquest and liberation of a great proportion of the European continent from the military dominion of France, and having subdued the conqueror, it took the state of possession as established by the peace under the protection of the alliance. It was never intended as an union for the government of the world or for the superintendence of the internal affairs of other states."‡ "No proof was produced to the British government of any design on the part of Spain to invade the territory of France; of any attempt to introduce disaffection amongst her soldiery; of any project to undermine her political institutions; and so long as the struggles and disturbances of Spain should be confined within the circle of her own territory, they could not be admitted by the British government to afford

any plea for foreign interference. If the end of the last and the beginning of the present century saw all Europe combined against France, it was not on account of the internal changes which France thought necessary for her own political and civil reformation, but because she attempted to propagate first her principles and afterwards her dominion by the sword."*

Law

188. The interference of the Christian powers of Europe in behalf of the Greeks, when groaning under the oppression of Ottoman misrule, was without doubt prompted by a desire to rescue a gallant and Christian people, to whom Europe was so deeply indebted, from the fate to which the ambition and cupidity of their governors had subjected them. Instances might have been cited from the history of international law which would have sanctioned an interference on a religious ground. From the time of the Crusades to the sixteenth century, when Protestant states confederated together to secure the religious freedom to the Protestant citizens of Roman Catholic communities, examples of this kind have been gathered; but it was thought more prudent in the treaty of alliance (London, 6th July, 1827), to state the *casus fœderis* in other terms. In the preamble of the treaty it is set forth, that the contracting parties were "penetrated with the necessity of putting an end to the sanguinary contest which, by delivering up the Greek provinces and the isles of the Archipelago to all the disorders of anarchy, produces fresh impediments to the commerce of the European states, and gives occasion to piracies, which not only expose the subjects of the high contracting parties to considerable losses, but besides render necessary burdensome measures of protection and repression."

Recognition of Greek independence.

189. As a consequence of the independence of a nation, its laws affect and bind directly all property within its territory, and all residents, native and foreign, and all contracts made and acts done within it.† They may regulate the enjoyment and transfer of property within its territory, fix the civil rights, capacities, and states of those who become its subjects by birth, domicile, or even temporary residence; they may determine the validity of contracts and other acts done within it, and the legal import which those contracts shall bear; and they may establish the forms and proceedings by which the judicial tribunals may entertain, investigate, and adjudicate on claims, and permit the execution within its own territory of foreign judgments. They do not, *proprio vigore*, operate beyond the territory of their state.‡ but the comity of nations (*comitas gentium*, or, as it is sometimes styled, *la nécessité ou bien public et général des nations*) recognizes them as operating universally, so far as they do not prejudice the independence of foreign states or the native rights of their citizens.§ The bounds and nature of this operation it will be our business briefly to consider. This involves the discussion of the *jus gentium privatum* and the *collisio legum*, or *conflict of laws*, to which the attention of jurists has of late been frequently directed.

Authority of the laws of a nation.

190. The subject is one of considerable difficulty, but

Law.
Real pro-
perty.

the following summary is sufficient for the purposes of the present essay:—

(1.) As to real property. The title to real property, its tenure, and the forms by which it is conveyed, are governed by the law of the place in which it is situate. If any question respecting these is raised before a foreign tribunal, such tribunal will adjudicate according to that law.*

(2.) As to personal property. Foreign states recognize and give effect to those laws which affect personal property, which, as its situs is that of the domicile, are such as prevail in the place of domicile.

(3.) As to the state and capacity of persons. This is generally governed by the law of domicile as to acts done, rights acquired, and contracts made in the place of domicile. If they are valid there, they are valid everywhere else.† But as to acts done, rights acquired, and contracts made in other countries, the law of the country in which they are done, acquired, or made will generally govern in respect of the capacity, state, and condition of persons. Personal disqualifications arising from the customary or positive law of a country—such as the disqualifications resulting from heresy, Popish recusance, &c.—are not recognized by foreign states or their tribunals. In questions of legitimacy, the *lex loci* of the marriage will generally govern as to the issue subsequently born. Acts or contracts done or made in a foreign country in evasion of the laws of the native country will not necessarily be recognized by that country. The rule cannot be laid down more positively, as it is obviously a matter of discretion.

(4.) As to contracts; their form, interpretation, obligation. A contract, if valid in the place where it was made, is usually considered as valid elsewhere.

These are general principles, but they cannot be taken as invariably true; the exceptions in some cases being so numerous as to invite the doubt how far they are to be considered principles at all. Mr. Burge, in his *Commentaries on Foreign and Colonial Law*, and Mr. Justice Story, the American jurist, have exhausted the learning on this subject, and to their works the reader is referred for further information.

191. Sovereigns and their diplomatic representatives while in a foreign country are considered not amenable to its laws; so also is a foreign fleet or army while within the territorial jurisdiction of a friendly state. The vessels, public and private, of every nation on the high seas are considered as subject to the jurisdiction of their country.

With the exceptions above mentioned, the judicial power of every independent state extends,—

192. (1.) To the punishment of offences against the laws of the state committed by foreigners as well as subjects within its territory or on board its vessels on the open seas or in foreign ports, and to the punishment of piracy and other offences against the law of nations.

193. (2.) To all civil proceedings *in rem* relating to personal or real property within its territory; and

194. (3.) To all controversies respecting personal rights and contracts, or injuries to the person or property, when the party resides within the territory, wherever the cause of action may have originated.‡

* 1 Burge, *Comm.* 25-9. *Locus regit actum* is the maxim of law: see *Trotter v. Trotter*, 1 Wilson & Shaw, *Appeal C.* 407; and *Curling v. Thornton*, 1 Addams, *Rep.* 21.

† Story, *Comm.* ch. iv. sec. 101.

‡ 1 Wheaton, *Elem.*

195. (III.) *The Right of Equality.*—One of the fundamental principles of public law generally recognized is, according to Sir William Scott, “the perfect equality and independence of all distinct states. Relative magnitude creates no distinction of right; relative imbecility, whether permanent or casual, gives no additional right to the more powerful neighbour, and any advantage seized on that ground is mere usurpation. This is the great foundation of public law, which it mainly concerns the peace of mankind, both in their politic and private capacities, to preserve inviolate.”* This great principle is, however, somewhat modified in its application, both by the usage of nations and by compacts, whereby the forms of international etiquette are defined and established. These may be considered as they relate (a) to the relative rank and precedence of states, (b) to their titles, (c) to the language employed in their negotiations, and (d) to their maritime ceremonials.

196. (a) Certain honours, denominated royal, are enjoyed by the empires and kingdoms of Europe, by the Pope, by the grand duchies of Germany, by the Germanic and Swiss Confederations, and, as we presume, the United States of America.† The right to send an embassy of the first order, the right of preceding all other states, together with several distinctive ceremonies, make part of the *royal honours*.‡

By the Roman Catholic states precedence is yielded to the Pope, who by the Protestant states is considered simply as the prince-bishop of Rome. The text-writers appear disposed to consider the great republics inferior in point of precedence to crowned heads; but these states have never acknowledged their inferiority, and the question has been by tacit consent of all parties suffered to fall into obscurity. Indeed the whole question of relative rank, as far as concerns states enjoying royal honours, was felt to be so doubtful as well as so delicate that, on the discussion, in the Congress of 1815, of the report of a committee appointed specially to consider the subject, it was resolved to leave it in its original state of uncertainty. The usage at present, as it appears, may probably be stated thus:—

197. Monarchs enjoying royal honours, without being crowned heads, give precedence on all occasions to crowned emperors and kings.

Monarchs not enjoying royal honours yield precedence to such as do.

Below this last class rank demi-sovereigns or dependent states.§

198. This matter of precedence never having been formally settled, various expedients are resorted to in order to avoid an inconvenient contest at the period of a negotiation, without compromising the rights of any party. Of these the best known is the usage of the *alternat*, by which the rank and places of various powers is changed from time to time in a certain regular order, or one determined by lot.|| For instance, in treaties between two powers two copies are prepared, and each power, in the copy it keeps, is named first. If there are several parties to the treaty, the same number of copies is made, and the same usage observed. The right to this alternation has sometimes been denied to certain states.

* The “*Le Louis*,” 2 Dodson, *Rep.* 243.

† This state never accredits ministers of the first class to any foreign power.

§ 1 Wheaton, *Elem.* 196.

|| *Ibid.* 197.

Law.
III. Rights
of equality.

Law.

The king of Great Britain refused to recognize the title of the King of Prussia to this privilege in 1742, and Hungary and Sardinia experienced great difficulties in obtaining admission to the alternation at the peace of Aix-la-Chapelle.* Sometimes it is arranged that the signatures to a treaty shall range according to the order assigned by the French alphabet to the respective powers parties thereto.†

Titles of states.

199. (b) While it is competent to any state to confer what title it pleases on its prince or chief magistrate,‡ it is not incumbent on foreign states to recognize that title, and sometimes when they do recognize it, a condition is annexed to the recognition. France and Spain recognized Russia as an empire, stipulating that the title of emperor should not affect the sovereign's precedence; but the Empress Catherine II., on her accession in 1762, refused to renew this stipulation, declaring, at the same time, that the imperial title should not alter the ceremonial between the two courts. France, in turn, renewed her recognition, with a declaration that if any such alteration were made, she would cease to give the imperial title to Russia. Neither the royal title for Prussia nor the imperial title for Russia were generally acknowledged until the powers of Europe had successively consented to them.§

Diplomatic language.

200. (c) With respect to the language employed in negotiation, in the early periods of diplomatic history, the Latin, as the European language, was that generally used; and this, towards the end of the XVth Century, was, in consequence of the political influence of Spain, superseded by the Castilian tongue, which, in its turn, was supplanted by the French, now the most usual medium of diplomatic intercourse. Some nations, as Spain and the German-Italian states, employ their own language; but it is customary for them, when treating with a power whose language is different, to transmit a translation of the treaty in the language of that power, if it is understood that the courtesy will be reciprocated. When both contracting parties have a common language, their treaties are worded in that language.||

Maritime ceremonials.

201. (d) With respect to maritime ceremonials, it may be observed that they have frequently formed subjects of contest between powers. The honours they involve are paid either by a salute with cannon, a salute with the flag, or with the pendant, by furling it up, lowering it, or hauling it quite down; or by a salute with sails by lowering or hauling down the foretopsail.¶

As far as its own maritime jurisdiction extends, every state may impose what regulations it pleases in respect of these ceremonials, but they are usually made the subject of express compact. On the open seas it is usual for an admiral to be saluted by a ship carrying only a pendant, if the ship belongs to a friendly power; and detached ships generally salute fleets.**

Right of property.

202. (IV.) *The Right of Property*.—"The dominion of a nation," says Vattel, "extends to everything which she

possesses by a just title. It comprehends the ancient and original possessions and all acquisitions made by means which are just in themselves, or admitted as such by nations—concessions, purchases, conquests made in regular war, &c."*

Law.

203. How far prescription may be considered as operating upon nations, jurists do not appear to have agreed; but the uniform practice of nations shows that they recognize the long and uninterrupted possession of a territory as excluding the claims of all other nations, and that this principle, whose exposition fills so large a head in municipal jurisprudence, is equally recognized, as reason dictates that it should in international law.

First occupancy.

204. As to national possessions, which being of comparatively recent acquisition, other sources of title are acknowledged: when the Russian government claimed the sovereignty of the north-west coast of America, from Behring's Straits to the 51st degree of northern latitude, they rested their claim, as they said, "upon the three bases required by the law of nations, that is, upon the title of first discovery; upon the title of first occupancy; and, in the last place, upon that which results from a peaceable and uncontested possession of more than half a century;† a space of time longer than that during which the United States had enjoyed a national existence. As to the two first sources of title named by the Russian envoy, they are unquestionably good as against every nation except that nation whose liberties their assertion may prejudice. The right of a state in quality of her superior power—the power lent her by her civilization—to subject to her dominion a territory inhabited by another people, be they ever so savage, may be questioned on the principles of the law of nations, however consistent with the customs and usages of nations. Vattel discusses the question, which is that of almost every European colony, "whether it be lawful to possess a part of a country inhabited only by a few wandering tribes?" and he justifies his reluctant assent to the affirmative on the ground that these tribes "cannot exclusively appropriate to themselves more land than they have occasion for," and that "their unsettled habitation in these immense regions cannot be accounted a true and legal possession."‡ An argument framed with a view to a conclusion does not deserve much mercy, and it may fairly be asked, (1) Who is to be the judge of the necessities of these tribes? Their usual occupations, hunting and fishing, notoriously require a large range of territory to enable them to support subsistence. (2) How, on Vattel's principles, can the integrity of the Russian empire, with its 150 inhabitants to every square mile of territory, be secured? Australia contains perhaps 5,000,000 of square miles, and a population truly insignificant. Surely this jurist's principle would impugn the inviolability of our dominion in that vast continent.

205. Still, as a fact, it is not to be denied that in savage countries the rights of the natives have in every instance been treated as subservient to those of the first Christian or civilized settler. Vattel's principle was carried further on one occasion by the British government, who, when Spain, on the ground of prior discovery and long occupation, confirmed by the treaty of Utrecht (in 1790), claimed the sovereignty of the

* Martens, *Précis*, liv. iv. ch. ii. sec. 6.

† 1 Wheaton, *Elem.* 198.

‡ Anciently the Pope and the Emperor of Germany claimed the right of conferring the royal dignity on any house they pleased. In this way the Emperor Henry IV., in 1086, made the Duke of Wratisslaus King of Bohemia, and Pope Eugene made Alphonso King of Portugal. The Pope for a long time refused to acknowledge Frederick as King of Prussia.

Law. north-west coast of America, as far north as Prince William's Sound (lat. 61°), asserted "that the earth is the common property of mankind, and of which each individual and each nation has a right to appropriate a share by occupancy and cultivation."* This is almost the language of the German chieftain of Nero's time: *Sicut diis cælum, ita terras generi mortalium datas, quæque vacuæ, respublicas esse.*

Property
in seas.

206. As to the extent to which the right of property operates; and first, as to the sea:—So much of the sea as is bounded by the territories of a state (such as St. George's Channel, which runs between England and Ireland) is considered as belonging to that state. And thus all harbours, ports, bays, and *embouchures* of rivers are considered as belonging to the state whose land forms their boundaries. The usage of nations has, for obvious reasons, extended this possession to as much of the open sea as lies within cannon range (that is, about three miles) of the shore,† in obedience to the maxim, *Terræ dominium finitur, ubi finitur armorum vis.* The term *shore* includes not only what is generally so denominated, but all islands lying off the coast, although not sufficiently firm for habitation;‡ but it does not include shoals. By the 9th Geo. II., c. 5, a jurisdiction of four leagues from the shore is assumed by the British government for revenue purposes, so that foreign goods transhipped within those limits are subject to the payment of duties.

207. Being "a claim of private and exclusive property over a subject where a general, or, at least, a common use is to be presumed," says Sir William Scott, "the general presumption certainly bears strongly against such exclusive rights, and the title is to be established on the part of those claiming under it in the same manner as all other legal demands are to be substantiated—by clear and competent evidence."§ Still the property in whole seas have at various times been claimed by various nations. Thus the possession of the Indian seas was claimed by Portugal, while the Venetian republic asserted similar pretensions to that of the Adriatic, the Ottoman empire to the Black Sea (subsequently renounced by the treaty of Adrianople in 1829), and Denmark to the Baltic.

Close and
open seas.

208. The question of *mare clausum* and *mare apertum* was formerly one of considerable interest, and occupies a large place in the writings of jurists. It may generally be stated, that while the sea (subject to the exceptions first mentioned) is for the most part open and common to all nations, as to certain parts the general right may be modified by compact and usage. Even Grotius, the stout advocate of the general right, is forced to admit that this is authorized by numerous passages in ancient writers, to whose authority on other subjects he is, in Mr. Bentham's opinion, always too ready to defer.|| Father Paul Sarpi, the well known

historian of the council of Trent, vindicated the claim of Venice to the supremacy of the Adriatic; and Bynkershoek (no mean authority) acknowledges that certain portions of the open sea may become the property of a state, grounding his denial of the claims of England to the Four Seas simply on the fact of a deficient length of possession.* Vattel, too, asserts that tacit agreement evidenced by a non-usage of the general right, may confer property or dominion in a sea.†

209. Secondly, as to rivers and lakes. These, when wholly included within the territory of a state, are its exclusive property, and every state is considered as possessed of so much of a river as flows through its territories. If the river divides two states, the mid-channel is considered as the boundary line, unless prior occupation has given to the one or the other the right of possession to the whole. In the case of rivers flowing through several states, all the nations inhabiting its banks possess the right of navigating it for commercial purposes. This is what is called an *innocent use*, and is considered to be subject to the convenience and safety of any state which its exercise may affect. This innocent use appears to involve the right of doing whatever is necessary to its enjoyment, such as mooring vessels to the banks, landing cargoes, &c.; but usually these, as well as the general right itself, are settled and determined by convention.

210. The right of navigation to which we allude may be renounced by treaty, as was the case in the treaty of Westphalia, whereby the navigation of the Scheldt was closed in favour of the Dutch provinces. The treaty of Vienna, in 1815, declared that the commercial navigation of the great rivers of Germany and ancient Poland should be open, provided that the regulations of the police were observed. These, it further declared, should be uniform and as liberal as possible to the commerce of all nations.‡

211. Having discussed those rights of nations which are intrinsic and result from their character as nations, we have now to consider such rights as are properly international, and originate in their mutual relations. These relations being either *pacific* or *hostile*, we may consider these rights as they have reference to a state of war or of peace.

212. (I.) The international rights of nations in their pacific relations are, the rights of legation and the rights of negotiation and treaties. The rights of legation are so fully treated of in another part of this work, that it is unnecessary we should consider them further in this place.§

213. As to the right of negotiation, certain public conventions are effected by subordinate powers, authorized thereto by the terms of their commissions and the nature of their duties. Thus the governor of a town and the general who besieges it have a power to settle the terms of the capitulation, and the authority to effect such an agreement being annexed in their respective offices, the capitulation is obligatory on the states whose servants and representatives they are.

214. Admirals and generals have usually authority, within the spheres of their review, to grant special licences to trade, cartels for the exchange of prisoners, capitulations, truces, &c.

* 1 Wheaton, *Elem.* 211. A singular admission of the rights resulting from discovery appears in the conduct of the Turkey Company in 1581, who being desirous of engaging in the Indian trade, and considering the passage round the Cape, discovered by the Portuguese, to be their exclusive property, and not to be interfered with, chose the overland route, where they were exposed to the powerful competition of the Venetians.—Macpherson, *Hist. of European Commerce with India*, p. 75.

§ Div. iv. vol. v. Art. DIPLOMACY.

Law. and truces for the suspension of hostilities; and these are conventions to the validity of which the ratification of their principals is not required, unless by express stipulation.*

Sponsio. 215. "By the Latin term *sponsio*, we express an agreement made by a public person who exceeds the bounds of his commission, and acts without the orders or command of his sovereign."† Conventions of this kind are not valid until they are ratified, which may be done either formally or by implication, as if one of the states whose agents effected the convention should cause troops to pass through the territories of the other on the footing of friends; this would be considered as a tacit ratification of the convention. Mere silence would not be so construed, although good faith requires that if one state does not purpose to recognize the acts of its servant, it should notify the fact to the other. If on the belief that the agent was duly authorized, the convention has been wholly or partially acted on by one party, it would seem it has a claim to be indemnified or replaced in its former position.‡

Ratification. 216. A minister, properly to conclude a public treaty, ought to be fully empowered by his state to do so; but before the treaty can be considered binding on the contracting parties, it is usual to require that it should be ratified by them. This power of ratification is generally reserved in a treaty, and no state should refuse to exercise it without a powerful reason, such as that the minister has not followed his instructions.§

Obligation of treaties. 217. It is for the internal constitution of every state to determine in whom the right of negotiating and effecting treaties resides; but treaties so far lawfully made are obligatory on the state. When the treaty requires the payment of money to carry it into effect, the legislature are morally bound to pass the law, because to the performance of the treaty the public faith has been pledged by competent authority. In such a case, however, it is usual for the British government to stipulate in the treaty that the crown will recommend to parliament to vote the necessary monies. If the treaty involves an alienation of the public domain, whether it be public or private property, it would seem to be obligatory on the party so contracting, if they are clothed by their respective states with the whole treaty-making power. And thus in a case decided by the Supreme Court of the United States, it was held as a clear principle of national law that private rights might be sacrificed by treaty to secure the public safety; although it was admitted—and Grotius is an authority on the point—that the government would be bound to compensate the individuals whose rights might be surrendered.|| The fundamental laws of a state may deny to the treaty-making power the right of thus alienating the public domain; in such a case the whole treaty-making power is not intrusted to one department of the state, and no treaty involving such an alienation would be obligatory, unless it were ratified by the legislature. Commercial treaties often require legislative sanction; and the commercial treaty of Utrecht, between France and England, was never carried into effect, parliament having rejected the bill necessary for that purpose.

218. Compacts between nations are either transitory

covenants (*pacta transitoria*) or treaties (*fœdera*), properly so called. When a transitory covenant has been fulfilled, and has continued without being renewed, or its future duration has been defined by the contracting parties, it still continues in force. Change in the person of the sovereign, the form of the government, or the sovereignty of the state, do not impair its validity, if any one of the parties do not violate it. A war only suspends a convention of this kind, and the return of peace restores its operation. Such are treaties of a first boundary or exchange of country, &c.*

219. Treaties cease to be obligatory when the sovereign power with whom they were made ceases to exist—when one of the states contracting changes her internal constitution so as to render the treaty inapplicable to her condition—and when a war breaks out between the parties. These two last rules are subject to exceptions. As to the first:—

220. Jurists distinguish between *real* and personal treaties. Personal treaties depend for their continuance on the person of the sovereign, or ruler, or his family. The former bind the state. The death of the ruler, extinction of his family, or the severance of his or their political connection with the state, dissolves the treaty. Political revolutions do not affect a treaty which is real.† The reader is referred to the Article on Diplomacy, already mentioned, for further information connected with this subject; the ceremonial etiquette connected with legations is therein fully detailed and explained.

221. War is defined by Vattel, as "that state by which we prosecute our right by force." It is with public war alone (that is, war carried on between independent nations) that the law of nations concerns itself. It may be *perfect* or *imperfect*, *civil*, or *national*, *offensive* or *defensive*.

222. A *perfect* war is, where a whole nation is at war with a whole nation, and all the members of one are empowered to exercise hostilities against all the members of the other. A perfect war.

223. An *imperfect* war is limited, as to persons, places, and things, as was the case with the hostilities authorized by the United States, against France in 1798.‡ An imperfect war.

224. A *civil* war is a war between members of the same state, and, according to Grotius, is a *public* war, as far as the government are concerned, and private on the part of the insurgents. A civil war.

225. A *national* war is a war between nation and nation, undertaken and carried on by the authorities, according to the political organization of the nation, constitutionally competent so to do.§ A national war.

226. A war is *offensive* on the part of the sovereign who commits the first act of violence against the other. Offensive war.

227. It is *defensive* on him who receives the first blow. Defensive war.

228. The sovereign power is alone possessed of authority to make war; a civil war of course does not fall within this observation.|| Authority of making war.

229. As far as the law of nations is concerned, every war commenced and prosecuted in form, and consistently with its principles, is just. The right of determining Just war.

Law.

under what circumstances it shall take up arms is the natural prerogative of every state, and is incidental to its right of independence. The law of nations simply regulates this right, and prescribes the mode in which it shall be exercised.

Declara-
tion of
war.

230. The custom of making a declaration of war to the enemy, previous to the commencement of hostilities, is of great antiquity, and was practised even by the Romans.* Louis IX. would not attack the Sultan of Egypt until he had sent him a herald to announce his intention of doing so. The earlier jurists, with the exception of Bynkershoek, generally consider a war, undertaken without this previous declaration, to be contrary to the law of nations,† and Grotius bases its necessity, not on the ground that an enemy may be put on his guard, but that it may be clear that the war is undertaken, not by private persons, but by the authority of the community.‡ Since, however, the peace of Versailles, in 1763, such declarations have been discontinued, and the present usage is, for the state with whom the war commences to publish a manifesto within its own territories, communicating the existence of hostilities, and the reasons for their commencement.§ The publication of this manifesto was looked on as so essential, that nations have demanded a restitution of everything taken before such publication; || but although this publication is usual, as being necessary for the direction of the subjects of the belligerent state,¶ it may be questioned whether its omission would have such an operation.** When war has once been declared, whether by manifesto or by acts equivalent thereto, it is a war not simply between governments in their politic capacities, but binding on their subjects.††

Confisca-
tion of
enemy's
property.

231. A nation in a state of war is considered authorized, on general principles, to seize the persons and confiscate the property of the enemy's subjects.‡‡ This is a principle which modern usage has practically modified to a considerable extent. Grotius himself considers that, as far as respects debts due to private persons, the right of demanding is only suspended by the war. Vattel, while admitting the general principle, qualifies it by the exception of immovable property (*les immeubles*), held by the enemy's subjects within the belligerent state, and which, having been acquired by the consent of the sovereign, cannot be sequestered without a breach of faith. Debts, and other things in action, he holds liable to seizure. He at the same time admits that "at present the advantage and safety of commerce have induced all the sovereigns of Europe to relax from this rigour. §§ The state does not touch even the sums which it owes to the enemy; everywhere, in case of war, the funds confided to the public are exempt from seizure and confiscation." In the absence of express convention,

by which this matter is sometimes regulated, the modern rule, according to Mr. Wheaton, is, that neither the property of the enemy within the belligerent state, nor the debts due to his subjects, are confiscated on the breaking out of war.* In England it has been usual, in maritime wars, for the government to seize and condemn, as *droits of Admiralty*, the property of the enemy found in her ports at the breaking out of hostilities; but as to the debts due to his subjects, we consider them as only suspended by the war, and as restored by the peace.† Our ancient law was, however, much more liberal than this,‡ and, in comparatively modern times, the subjects of an enemy "residing here and demeaning themselves dutifully, and not corresponding with the enemy," have been, with their effects, taken under the special protection of the crown.§

232. It would appear that persons *domiciled* in the enemy's country are subject to reprisals as well as the natives.|| The nature of the residence which constitutes the domicile is determined in several cases decided by our courts.¶ If a person during hostilities enters a house of trade in the enemy's country, or continues the connection during war, his residence in a neutral country will afford him no protection.** There is no principle of international law more undoubted than that which prohibits all trade between belligerent nations, unless authorized by their governments,†† as it renders void all commercial contracts between subjects of the same. A remittance of supplies to a colony during its temporary subjection to an enemy is equally prohibited, although permission had been given to export the produce of that colony.‡‡ Numerous expedients have been resorted to by English merchants to evade the operation of this rule; but they have been effectually defeated, by the determination of our municipal courts to enforce it with the utmost strictness.§§

233. The rule extends equally to allies: "Between allies," says Sir William Scott, "it must be taken as an implied, if not express contract, that one state shall not do anything to defeat the general object. If one state admits its subjects to carry on an uninterrupted trade with the enemy, the consequence may be, that it will supply that aid and comfort to the enemy which may be very injurious to the protection of the common cause, and the interest of its ally."||| This prohibition operates of course no further than the necessity which justifies it, and has no existence when the trade is of such a nature as can in no manner interfere with the common operations, or has the allowance of the confederate state.

234. The modern law of nations prohibits those barbarous customs which distinguished the warfare of early times. Considering war simply as a means to protect nations in the enjoyment of their just rights and lawful

Law.

possessions, it condemns all cruelty not absolutely necessary to secure that end. If to anything further than the progress of civilization, and the more general appreciation of the dictates of natural justice, consequent on the diffusion of a purer and sincere spirit of religion, the benevolent aspect in which war is thus regarded may be ascribed with some propriety to the influence which the writings of Grotius have exercised on international law. Even against the language of some of those authorities, in whom his confidence has been esteemed too implicit, this great and eminently wise publicist has protested, in eloquent terms, against those practices which the customs of the times had sanctioned, and which regarded war as incompatible with moderation, and a regard to the maxims of ordinary humanity. Wolf and Bynkershoek, subsequent to his age, considered that no measures which could injure an enemy were improper; but these writers, however highly esteemed on other points, have not in this prevailed; and a disposition has been constantly manifested, by the enlightened nations of Europe, to mitigate the horrors of hostilities, as far as is consistent with the occasion which produces and justifies them. The laws of war will now occupy our attention.

Laws of war.

235. It is now universally agreed, that hostilities can be undertaken by none who are not lawfully authorized thereto by their sovereign, or the supreme power of the state to which they belong. This does not of course prohibit the subjects of a state, when attacked, from defending themselves;* but it has been contended, though on what principle of justice it does not appear, that even such would be treated by the enemy with more rigour than those acting under the express orders of their superior.† Captures, however, made by a private armed vessel, without a commission, are not considered as piratical;‡ but the property seized does not pass to the captors, but is condemned to the crown,§ as prize of war, or, as it is styled, droit of Admiralty. The same result follows when vessels commissioned against one power seize the property of another, with whom war afterwards breaks out. This probably arises from the recognized distinction, maritime and land warfare;|| but it does not appear to have been approved by Sir Matthew Hale.¶ Modern writers** have deprecated the employment of privateers; that is, private cruizers commissioned by the state.†† The question of the liability

of the owners and officers of privateers in damages for illegal acts, beyond the security given,* is a question of municipal and not international law, and therefore cannot properly be discussed here; so likewise is their interest in the captures made.† It seems to have been settled, Privateers that a cruizer commissioned by two powers is to be treated as a pirate, even although the two powers are allies,‡ and many states have prohibited their subjects from arming in any way the fitting out of private vessels, intended to cruize against the subjects of friendly powers. The French Marine Ordinance of 1681 considered such an act as piratical.§

236. The law of nations prohibits as unlawful the use of Unlawful certain means of offence, such as poisoning,|| assassina- arms, &c. tion, and, according to Martens, the loading of cannon with nails, pieces of iron, &c.¶ The same writer considers as properly exempt from the extremities of war, children, women, old men, and others incapable of bearing arms, and such retainers of the army as are not employed in actual warfare;*** and also soldiers and others actually so employed, who have submitted, and entreated quarter. As to these last, he contends that their treatment will be subject to three considerations:—

237. (1) Whether sparing their lives will be consistent with the safety of the conqueror? (2) Whether he has a right to subject to the *lex talionis*?†† (3) Whether they have become his captives through their commission of a crime worthy of death, or whether they are spies, &c.?

238. The distinction to which we have before alluded is Distinction founded on the circumstance, that the presumed object between maritime and land warfare. of maritime warfare is “the destruction of the enemy’s commerce and navigation—the sources and sinews of his naval power, which object can only be attained by the capture and confiscation of private property;” while the object of wars by land is treated as being “conquest, or the acquisition of territory, to be exchanged as an equivalent for other territory lost.” In this latter, “the regard of the victor for those who are to be, or have become, his subjects, naturally restrains him from the exercise of his extreme rights in this particular.”††

239. A prisoner of war is entitled to protection and Prisoners good usage, but may be strictly confined if he attempt of war. to escape. Officers are frequently liberated on their parole, or word of honour, that they will not serve against the power by which they are released during the war, or during a stipulated time. The exchange of prisoners

* Vattel, liv. iii. ch. xv. sec. 223. Dig. 47, 22, 4. Vattel (sec. 225) considers this to be a rule relating rather to public law in general than to the law of nations properly so called; but unquestionably it is a rule adopted by the law of nations, by which it is enforced, as is apparent from the difference of treatment to which unauthorized belligerents are exposed from that which the regular combatants are subjected.

Law. during the continuance of hostilities is a practice common to all civilized states.*

Exchange of prisoners. 240. The persons of artisans, labourers, merchants, and persons whose occupations are peaceful, it is customary to respect.

Enemy's property. 241. As to the enemy's property:—In the rigour of international law, to capture or destroy this is lawful; but this rigour has been mollified by the humane usages of nations, which have acquired the force and obligation of laws. A distinction must, however, be taken between at sea; hostile operations conducted on land or at sea. It is in land warfare that the progress of civilization has most decisively manifested itself.

on land. 242. The religious edifices, works of art, repositories of sciences, and public buildings of a decidedly civil character, belonging to an enemy, are considered as sacred from spoliation and destruction by the customs of all enlightened nations.† Private property on land is also respected, subject to occasional certain exceptions: (1) property taken from the enemy in the field; (2) property in a town taken by storm, after having repelled all overtures for a capitulation; and (3) contributions levied by a belligerent, for the support of his army, and towards defraying the expenses of the war.‡ In a case of extreme necessity, it is lawful to devastate and lay waste an enemy's territory, and to destroy all buildings, &c., therein as far as is requisite for the success of military operations, but the lawfulness of such proceedings is limited by that necessity in the view of Retaliation all communities.§ A departure from these rules will be justified, it is thought, by the *lex talionis*, which is considered to exercise a vast influence in modifying the humane usages of modern warfare.

Captures. 243. When the capture has been effected, the title to the property so captured is considered, as between belligerents, to pass from the original owner to the captors. The law of rule is, that the transfer is effected by occupation. *Occupatione dominium prædæ hostibus acquiritur.*|| A possession for twenty-four hours is, according to Grotius¶ and others, essential to this transfer; and although Bynkershoek** does not concur, this appears to be sanctioned by modern authority.††

244. In the case of ships and goods taken at sea, the title does not pass until the validity of the capture has been affirmed by a competent prize court of the captor's government,‡‡ sitting in its own country. §§ By the practice of Great Britain and the United States, their prize courts may try captures, which have been carried into neutral ports. |||| When the capture has been effected within, or by vessels fitted out within the territorial limits of a neutral state, the tribunals of that state have juris-

diction to try the capture, and some, as the price of the permission they afford belligerents to bring their captures into their ports, have, by their municipal laws, reserved a right of adjudicating on such captures, when the original owners of the captured property have been their subjects, and of restoring the property to them.* The right of condemning prizes is one that no neutral state can concede to a consular tribunal sitting within her territories.† The sentence of a competent prize court renders the title of the captor conclusive, as far as personal property is concerned.‡ The distribution of this property is a matter regulated by the internal laws of every state. Whatever is captured is, in intendment of law, captured by the state; *bello parta cedant reipublicæ*,§ although the common law of England considers it otherwise.||

245. The law of Postliminy is one of the few portions of the Roman *Jus Feciale* which has descended to us. Jus Postlimini. By this law, according as it is at present understood, if a vessel, even although it has been two or even four years in possession of the captors, be recaptured *before* condemnation by a ship belonging to the country of the original owners, they may claim its restoration, on paying a proper salvage to those by whom the recapture has been effected.¶ The operation of this law, as far as concerns cases arising between her own subjects, or between her own subjects and those of such of her allies as evince a disposition to a reciprocal liberality, has been extended by Great Britain to any recaptures effected during the war, and without regard to any sentence of condemnation having passed.** The right of postliminy takes place only within territories of the captor's nation, or its allies, and does not include neutral countries.†† It is, however, in reference to real property that an allusion to this law is chiefly necessary; and it is this law which avoids, on the return of peace, all alienations of such property, by a belligerent state, in occupation of the enemy's country. To impart stability to them, they must be confirmed by the treaty of peace.

246. The observance of good faith to an enemy is one of those duties on the obligation of which all jurists unite, and which it is the obvious interest of all belligerents to practise.†† Good faith towards an enemy.

247. We have, in concluding this rapid review of the laws of war, to consider those relaxations of their stern rigour, which are familiar to modern, and in some degree even to ancient practice. (1) A truce is a suspension of hostilities, either for a long or indefinite period, or sometimes only as to a portion of the military operations. The authority to effect the former is not always implied in the authority of the commanders, but usually so as respects the latter. Whenever effected, a truce is obligatory on all the subjects of the belligerent states, after it has been duly promulgated. (2) The right to effect capitulations for the surrender of fortresses, &c., is involved in the authority committed to every commander

Law.
Passports,
&c.
Licences to
trade.

by the terms of his commission. (3) Passports, safe conduct, and licences are granted in war, for the protection of persons and property. Licences to trade are the most important of these. Grotius considers that the interpretation to be put on these permissions should be liberal rather than strict, *laxa quam stricta interpretatio admittenda est*.^{*} Sir William Scott adopted a different principle, and considering a licence as a high act of sovereignty, and consequently *stricti juris*, concluded that it "must not be carried further than the intention of the great authority which grants it may be disposed to extend." It is not "to be construed with pedantic accuracy," nor should "every small deviation be held to vitiate it. An excess in the quantity of goods permitted might not be considered as noxious to any extent: a variation in the quality or substance of the goods might be more significant, because a liberty assumed of importing one species of goods under a licence granted to import another might lead to very dangerous abuses."[†] The time mentioned in the licence must not be exceeded,[‡] and the port of shipment therein named is a material point.[§] A greater liberality of construction has been evinced by the courts, when the question has respected the parties for whose advantage the licence has been obtained.^{||} It has been decided that a general licence is to be construed so far strictly as not to extend to a protection of an enemy's property,[¶] but a licence specifying any flag protects even an enemy's property.^{**} The conditions contained in a licence must, to render it valid, be truly and fairly performed;^{††} and it is a permission which the war is considered to terminate.^{‡‡} In the first instance it must be granted by competent authority,^{§§} circumstances sometimes forbidding property captured at sea to be sent into port. The captor, according to the general law of nations, may either destroy it or permit the original owner to ransom it. The effect of a ransom is to give, on the authority of the state to which the captor belongs, a safe conduct to the vessel captured, which will protect it from all cruizers of that state. By the 22 Geo. III. c. 25, British subjects are prohibited from ransoming enemy's property.

Ransom.

Rights of
war as re-
spect
neutrals.
Definition
of neutra-
lity.

248. We have now to discuss the rights of war as concerns neutral nations. Properly "neutral nations are those who in time of war do not take any part in the contest, but remain common friends to both parties, without favouring the arms of the one to the prejudice of the other."^{|||} To be neutral, the nation should give no assistance when she is under no obligation to give it. In whatever does not relate to war, she is not on account of his present quarrel to deny to any of the parties what she grants to the other. Such conduct is the very essence of neutrality, and a nation forfeits her neutral character when she departs from it. It does not necessarily, however, preclude her, if so bound by treaty previous to the war, furnishing a belligerent party

Qualified
neutrality.

^{|||} Vattel, liv. iii. ch. vii. sec. 103.

with a limited succour in money, troops, ships, or munition, or from opening her ports to receive his prizes. From such an obligation he is said to be released if his ally be the aggressor in the war.^{*} Hostilities cannot lawfully be exercised within the territories of a neutral state, the common friend of both parties. Nor can such neutral state permit, to one or certain of the belligerent parties, the passage of their armaments through her dominions, unless she is prepared to concede a like indulgence to the opponents. Such a preference would destroy her neutrality.

249. A neutral territory must not be violated for the purposes of war. No capture effected within its limits is lawful; and, when illegally made, the neutral state is bound to restore it to its original owners. Nor can such capture be lawful when made by a vessel hovering at the mouth of the river, or bays, or round the coast of a neutral. Bynkershoek[†] has excepted from this rule a vessel chased within a neutral jurisdiction, whither he thinks the belligerent may follow and capture her; but this doctrine, though it has not wanted supporters, is now generally disowned.[‡]

Neutrality
of a terri-
tory not to
be violated.

250. The restitution of property, illegally captured within neutral limits, is effected by an application to the captor's government, by the neutral state, as it is her rights which the law considers to have been violated, and the hostile claimant has no right to appear for the purpose of suggesting in the validity of the capture.[§]

Illegal
captures in
neutral
states.

251. A belligerent cruizer innocently passing through a neutral jurisdiction is not considered to have violated its rights, so far as to invalidate a subsequent capture; and a neutral is not compelled, in virtue of his neutrality, to deny such a passage, nor even to refuse to a belligerent vessel pursued refuge in its harbours; but it ought not to permit it to lie there, and wait a favourable opportunity of renewing a conflict. It need not deny to such vessel provisions and refreshments, which the law of nations universally tolerates; but no proximate acts of war are in any manner to be allowed to originate on neutral ground.^{||} For this reason, when belligerent vessels meet in a neutral port, or one pursues the other there, hostilities cannot be permitted between them during their tarrying; but should one sail, the other must not follow for twenty hours: such at least is the opinion of Professor Martens.[¶]

Conduct
of neutrals
towards
bellige-
rents.

252. A neutral state that permits the arming and equipment of ships or troops for the purposes of a war within its territory violates its neutrality;^{**} but it is no breach of neutrality to suffer a belligerent to bring in his prizes for the purposes of sale.^{††}

Permission
to arm in a
neutral
territory.

253. It may be here remarked that, if a neutral acquiesces in an outrage inflicted on him by one belligerent, the other has a right to retaliate; and that if a deed interdicting a neutral from trading with us, or visiting our ports, is executed upon him, it is an interdiction he has no right to submit to, because its execution will be our injury. If his submission is the result of favour to the belligerent, the neutral becomes constructively a party to the war, and his neutral character with its consequent immunities terminates forthwith. If, on the other hand, it

Acqui-
escence of
neutral in
an outrage

Law.

originates in his weakness and inability to resist, we may insist, for our own protection, and without denying to him his neutral character, that what he has suffered from our enemy he may suffer from us, otherwise he would be keeping an open trade with the enemy to our disparagement, and becoming an instrument of its illegal pressure on our resources.*

Commerce of neutrals.

254. As to the commerce of neutrals, it has been decided,† that not only has a neutral a right to pursue his general commerce with the enemy, but even to act as the carrier of the enemy's goods, from the enemy's country to his own, without being subject to the confiscation of the ship, or of any *neutral* goods on board. This is a right which was formerly disputed, but which is now universally recognized; and the neutral owner, when the enemy's goods on board his ship have been seized, is considered entitled, provided his conduct has been fair, to his reasonable demurrage, and his claim for freight.‡

Enemy's goods on board a neutral vessel.

255. That a belligerent is entitled to seize an enemy's goods on board a neutral vessel is an undoubted principle;§ if, however, it should appear that the enemy's interest in the goods was only partial, or that they were the joint property of an enemy and a neutral, the share of the neutral will be saved harmless, and that of the enemy alone confiscated.|| It has been, however, usual in commercial treaties, to stipulate that free ships shall make free goods, and thus this principle, like many other principles of international law, as we have frequently had occasion to observe, has been modified by convention.

The effects of neutrals on board enemies' ships are, upon general principles, considered as exempt from confiscation.¶

Contraband of war;

256. The freedom of commerce to which neutral states are entitled does not extend to *contraband of war*, such as warlike stores and other articles directly auxiliary to warlike purposes.** "The catalogue of contrabands," says Sir William Scott, "has varied very much, and sometimes in such a manner as to make it very difficult to assign the reason of the variations, owing to particular circumstances, which have not accompanied the history of the decisions."†† Grotius distinguishes between those articles which are useful only for the purposes of war, those which are not so, and those of indiscriminate use in war and peace. With other writers, he agrees in prohibiting to neutrals the carrying of the first to the enemy; the second he permits; the third he sometimes permits, and sometimes forbids. Bynkershoek‡‡ considers that the third ought, under no circumstances, to be considered contraband, and the whole question is involved in much confusion. "In 1673," says Sir William Scott, "when many unwarrantable rules were laid down by public authority§§ respecting

contraband, it was expressly asserted by a person of great knowledge and experience in the English Admiralty that, by its practice, corn, wine, and oil were liable to be deemed contraband. In much later times, many sorts of provisions, such as butter, salted fish, and silk, have been condemned as contraband. The modern established rule was, that generally they are not contraband, but may become so under circumstances arising out of the peculiar situation of the war, or the condition of the parties engaged in it. Among the causes which tend to prevent provisions from being treated as contraband, one is that they are of the growth of the country which exports them.* Another circumstance to which some indulgence by the practice of nations is shown, is when the articles are in their native and unmanufactured state. Thus iron is treated with indulgence, though anchors and other instruments fabricated out of it are directly contraband. Hemp is more favourably considered than cordage. Wheat is not considered so noxious a commodity as any of the final preparations of it for human use. But the most important distinction is, whether the articles are destined for the ordinary use of life or for military use. If the port is a general commercial port, it shall be understood that the articles were going for civil use, although occasionally a frigate or other ships of war may be constructed at that port. On the contrary, if the great predominant character of a port be that of a port of naval equipment, it shall be intended that the articles were going for military use, although merchant ships resort to the same place.‡ It is the *usus bellici* which determine an article to be contraband."

The transportation in a neutral vessel of military persons or despatches in the service of the enemy exposes the vessel to confiscation.§

257. The penalty of confiscation for engaging in a contraband trade is not held generally to attach, if the goods are not taken *in delicto*, and in the actual prosecution of the voyage;|| but a different rule is held to apply to cases of contraband carried from Europe to India, with false papers and false destination, intended to conceal the real object of the expedition, where the return cargo, the proceeds of the outward cargo taken on the return voyage, was held liable to condemnation.¶¶

258. The *rule of the war of 1756*, as it has been called, has formed so frequently a subject of controversy amongst publicists that it cannot be passed over without remark. The superiority of Britain as a naval power was conclusively established by the war with France in 1756, when the communication of this latter country with her naval power was effectually interrupted by our fleets. In order to avert the disastrous consequences with which the French colonies were threatened, their government permitted a neutral power, the Dutch, to carry on the trade, the advantages of which had previously been enjoyed

Law.

by the French marine exclusively. Some of these Dutch vessels, having been captured, were condemned on the principle stated by the Court of Appeal in the case of the "Wilhelmina."* "By the general law of nations, it is not competent to neutrals to assume in time of war a trade with the colony of the enemy which was not permitted in time of peace."† This principle applies equally to all species of trade, whether coasting or colonial trade. The extent to which it has been relaxed, and the arguments which have been urged against it as a principle, we have no space here to discuss.

259. "The law of blockade," says Bynkershoek,‡ "is founded on the principles of natural reason as well as on the usage of nations. In order that this law may apply, (1.) there must be an actual blockade in existence."§ The mere declaration of a blockade will not suffice. An adequate naval force must be stationed at the blockaded port; and properly "that denomination is given only where there is, by the power which attacks it by ships stationary or sufficiently near, an evident danger in entering."|| An accidental absence of the blockading squadron, provided the blockade is speedily renewed, forms an exception to the rule, and an attempt to take advantage of the absence to break the blockade is considered fraudulent.¶

(2.) The neutral must have had notice of the existence of the blockade. It is usually notified to all neutral governments, and "it is the duty of foreign [neutral] governments to communicate the information to their subjects, whose interests they are bound to protect. I shall hold, therefore, that a neutral master can never be heard to aver against a notification of blockade that he is ignorant of it."** This is a case where the blockade has been notified to the government; but if the individual is personally informed of it, the consequences are the same.

To enter or quit a blockaded port with a cargo laden after the commencement of the blockade is punished with confiscation of the ship and cargo, and the offence is not considered discharged until the end of the voyage.

260. The right of visiting and searching merchant ships on the high seas exists "for the purpose of ascertaining what the ships and their destination are :†† and the penalty for a violent contravention of this right is the confiscation of the property so withheld from visitation and search.‡‡ But the forcible resistance of an enemy master will not in general affect neutral property laden on board of an enemy's ship.§§

261. We may notice that the English Court of Admiralty held a neutral to have no right to charter and lade his goods on board a belligerent armed merchant ship, without forfeiting his neutrality;||| but this is a

doctrine which the American Courts have refused to sanction.*

262. How far neutral vessels, under an enemy's convoy, are subject to capture is still a moot point.

Sect. 6. Sanctions of the Law of Nations.

263. Having thus detailed the fundamental rights which either result from, or are secured by, the law of nations, we proceed to explain the sanctions by which such rights are enforced. These sanctions are of various kinds, and forcible in various degrees. They may, however, be reduced to two classes :—

264. (1.) Reprisals.† There are two kinds :—*negative*, Reprisal. when a state refuses to fulfil its obligations, or to permit another nation to enjoy rights which it claims. They are *positive*, when they consist in seizing persons and effects belonging to the other nation in order to compel them to give satisfaction.‡ Reprisals may also be either *general* or *special*. They are styled *general* when a state, General. which has, or supposes it has, received an injury from another, formally commissions its subjects to take the persons and property of the other state wherever they may be found. "I do not," said De Witt, "see any difference between general reprisals and open war."§ They are, in fact, according to modern usage, the first step taken at the commencement of a war, and considered equivalent to a declaration of hostilities, unless an immediate satisfaction is made by the other state.|| *Special* Special. reprisals are where letters of marque are granted in time of peace to individuals who have suffered an injury from the governments or subjects of another nation. These were common in very early times in England, and are specially authorized by the 4th Hen. V., cap. 7. They have been regulated by treaties; by those of Munster between Spain and Holland in 1648; by those between England and Holland in 1654 and 1667; by that of Rhyswick in 1697; and of Utrecht in 1713; by the French Ordinance of Marine in 1681; by the Articles of Confederation of the United States of America in 1781, and by the treaty between that republic and the republic of Columbia in 1825 (1 Kent, *Comm.* 61). This kind of reprisals in time of peace has, however, been condemned generally by the jurists, and has fallen into almost total and deserved disuse. The effect of the confiscation of the property of a foreign state antecedent to an open rupture is ably

* 2 Wheaton, 257.

† Many writers on the law of nations have discussed, in connection with this subject, the law of retaliation, *lex talionis*. This is not, however, a sanction of the law of nations, as it is not a punishment for the violation of any principle of that law. Retaliation ensues the breach of what are called *imperfect obligations*, and which do not justify a resort to forcible measures. Where a state, for instance, is guilty of the breach of a simple custom, or establishes some partial right or law prejudicial to foreigners, the state whose citizens are prejudiced retaliates by exposing the citizens of the offending state to similar disadvantages. This is amicable retaliation (*retrosion de droit*).—Martens, *Précis*, liv. viii. ch. i. sec. 2. Vattel, liv. ii. ch. xviii. sec. 339-41; 2 Wheaton, 4.

Law.

explained by our jurist, Sir William Scott, on occasion of an embargo laid on Dutch property, after the breach of the treaty of Amiens in 1803, under circumstances which Great Britain considered an hostile aggression on the part of Holland: "The seizure," he said, "was at the first equivocal, and if the matter had terminated in reconciliation, the seizure would have been converted into a mere civil embargo, so terminated. Such would have been the retroactive effect of that contrary course of circumstances. On the contrary, if the transaction end in hostility, the retroactive effect is exactly the other way." — (The "*Boedes Lust*," 5 Robinson, *Rep.* 246.)

265. (2.) War. On the subject of war, we have already spoken at length; and here we may observe, that the long discussions in which jurists have indulged themselves, respecting the justice and injustice of wars, pertain rather to morals than to law. Every nation, in right of its independence, is justified in commencing any war when it sees fit: no other state has a right to dictate to it in this—the exercise of its own sovereignty. That all wars prosecuted in obedience to the rules of the law of nations are by that law treated as just, is evinced by the fact, that in every such case the nations engaged are considered entitled to the benefits, and subject to the obligations, which the law of nature imposes.

Law.

LAW.

CHAPTER III.

ROMAN LAW.

Sect. 1. Introduction.

Law. 266. THE history of legal systems is a subject of great interest to philosophic minds, though it does not possess the popular attraction of ordinary history. The details of political strife;—of wars begun, continued, and ended;—of treaties made and broken;—such is the stuff of which ordinary history is made. We love to hear of battles,—to follow the fortunes of a nation in prosperous and in adverse times,—to watch the windings of diplomatic intrigue,—to sympathize with the fate of our adopted party. But our study of ordinary history may have higher aim than mere intellectual pleasure. We may call forth our mental powers and our moral feelings into wholesome exercise, while we rejoice with the success of virtuous heroism, of patriotic spirit, of honest simplicity,—or mourn over the triumphs of fraud, ambition, and violence, while we investigate the causes of national improvement or decline, and seek to deduce general principles of policy applicable to other times and circumstances.

In strictly *legal* history,—at least, in the history of private law,—there is not so much to excite popular interest. There is little of romance in the detail of its progress. It presents no Marathon,—no Cannæ,—to our view. Yet some of the greatest minds have felt its claims to deep attention. “What,” to use the language of Burke (*Abridgment of English History*, ch. ix.), “can be more instructive than to search out the first obscure and scanty fountains of that jurisprudence which now waters and enriches whole nations with so abundant and copious a flood;—to observe the first principles of right springing up, involved in superstition and polluted by violence, until by length of time and favourable circumstances it has worked itself into clearness;—to view the laws, sometimes lost and trodden down in the confusion of wars and tumults, and sometimes overruled by the hand of power,—then victorious over tyranny, growing stronger and more decisive by the violence they have suffered; enriched even by those foreign conquests which threatened their entire destruction; softened and mellowed by peace and religion; and improved and exalted by commerce, by social intercourse, and that great opener of the mind—ingenious science.”

In this celebrated passage, Burke dwells principally on those *pleasures* of scientific contemplation which legal history affords; but it has also its practical *uses*. We cannot enlarge our acquaintance with human nature, and extend our knowledge of the dealings of God with men, without acquiring powers which may be wielded for good or for evil. By a philosophical study of legal history we learn the means of producing certain results,

and,—inasmuch as our moral approbation of laws may often depend, in some measure, on our observation of their effects,—we are furnished with additional data for estimating the propriety or impropriety of any proposed enactment. As the natural philosopher, during the performance of an experiment, endeavours, with comprehensive eye, to observe all the concomitant circumstances, and watches the successive changes which take place; so will the jurist survey the workings of ancient legislation, and, relying upon a certain constancy in human nature,—after making allowance for causes in operation now and not formerly, or formerly and not now,—will expect some identity in the residuary phenomena. It is true, indeed, that the theory of legislation, conversant as it is with the behaviour of moral agents capable of originating force, is liable to be affected by many capricious disturbances. It is also true that the course of legislation is, to a considerable extent, determined by circumstances,—such as soil, climate, race, antecedent history,—to which the systematic calculations of science can oppose little or no effectual resistance. Great caution is requisite in any attempt to transfer the institutions of one country to a people of different temperament, manners, and habits. The law may be good for Rome, which would be intolerable in Constantinople or in London. We may elicit principles and discover tendencies; but in the application of our principles, a tolerable approximation is all that can in general be hoped for. Still, it is something that a scientific lawgiver may even approximately predict the consequences of a law: some scope is still left to human energy and wisdom, acting with the weapons which experience furnishes. When the conscientious statesman reflects that his own feeble oars, plied with vigour and skill, may stem the drifting of a current, and that the laws which he introduces or supports may impress a new direction on the course of his country's fortunes, he will feel a deeper responsibility and be encouraged to redoubled efforts. The practical advantages of legal history, notwithstanding the inevitable drawbacks we have adverted to, are great and manifold.

The remarks which we have made with respect to legal history are applicable, more or less, to the study of *all* systems. There is no system, however barbarous and remote, from which some lessons of experience may not be drawn, and applied to existing events. It is with comparative history as with comparative anatomy; the dissection even of monsters and of brutes will enable the scientific physician to understand with clearer insight the functions, structure, and diseases of an ordinary man. There is no system in which, abstract-

Law.

On the peculiar claims to attention of the history of Roman law.

Law.

ing from practical application, we may not gratify our natural curiosity by diving into the recesses of human nature, and gaining a more extended prospect of the dispensations of Providence.

Ancient
Eastern
lawgivers.

We may read, with pleasure and instruction, the earliest accounts of the incipient legislation of hunters, fishermen, pastoral and agricultural people;—may view, as in a picturesque panorama, the priests of Egypt and the Brahmins of India;—may regard, in the sluggish dynasties of the East, the birth and pilgrimages of those philosophic legislators whose dim figures appear through the mists of mythology with an undefined, but gigantic, outline; and may follow the footsteps of Orpheus, Musæus, or Pythagoras, as they travelled to enrich the versatile West with mutilated and corrupted, but still valuable, treasures of holiness and wisdom.

The Jew-
ish law.

The theocratic legislation of the Jewish people presents views of still higher, but of very different, interest. The importance of the Mosaic Law to the jurist is not small, even when we abstract those religious considerations which more properly belong to the province of the divine. But Christians have occasionally erred in attempting to apply to the circumstances of modern times rules and institutions adapted only to the unique position of a peculiar people. Selden, in his treatise *De Jure Naturali et Gentium juxta Disciplinam Ebræorum*, endeavours to separate the laws which exclusively bind the Hebrews from those which are of universal obligation. In such researches there is obviously much danger of incorrect interpretation and of incorrect reasoning from analogy. In supernatural revelations of the Divine will we should rather look for general rules applicable to the *hearts* of men than expect to discover in detail political maxims and legislative principles intended for the compulsory regulation of their external conduct. The historical records of the *Old Testament* are, without doubt, intended to inculcate by example some lessons of general importance to the temporal interests of nations;—to show that righteousness exalts, —to show that sin is a reproach; and in this sense we may yield our assent to the noble lines of our own Milton (*Paradise Lost*, iv. 357), when he speaks of the Jewish prophets—

“As men divinely taught, and better teaching
The solid rules of civil government
In their majestic, unaffected style,
Than all the oratory of Greece and Rome.
In them is plainest taught, and easiest learnt
What makes a nation happy and keeps it so,
What ruins kingdoms, and lays cities flat.”

If, however, we read the polemical pamphlets and sermons of the time of the civil wars in the reign of our first Charles, we shall often meet with passages where the special institutions which seem to be expressly intended (among other purposes) to distinguish and separate the Jews from the Gentiles are quoted as universally binding; and where the special commissions given to the children of Israel to subjugate the land of Canaan, and to execute the judgments of Jehovah upon idolaters, are treated of as precedents of the *jus belli* applicable to existing events.

The work of Michaelis (Joh. Dav.), *Gründliche Erklärung des Mosaischen Rechts* (8vo.; Frankfort, 1776-1780), is one of the best commentaries upon the Law of Moses. It was translated into English by Alexander Smith, D.D., Minister of the chapel of Garrioch, Aberdeenshire (London, 1814; 4 vols. 8vo.) In giving it this character we must by no means be con-

sidered as sanctioning many of the opinions and views found in it, and still less as approving the prurient spirit in which many parts of it are written. There are some able remarks on the Mosaic Law in the *Notices of the Mosaic Law*, written by the late Hugh James Rose, in which the works of M. B. Constant and M. Salvandy on this subject are animadverted upon. There are also many useful reflections in the admirable *Lectures* of Dean Graves upon the *Pentateuch*; but the questions to which this writer directs attention are rather theological than legal.

The early legislation of the Grecian states is involved in uncertain tradition. The greater part of their legal systems was probably indigenous and the result of gradual development, although the Grecian authors, in their fondness for historical theories, usually attributed to foreign derivation any law or custom to which they discovered a resemblance in foreign countries. We cannot, however, reject the tradition that many of their most ancient lawgivers borrowed from Oriental sources, and introduced. *per saltum*, novel rules into preceding institutions; but we regard with scepticism the details of such introduction. As we English are prone to attribute to Alfred a great number of reforms in which he had no share, so the Grecian historians have a tendency to the mythical idealization of such lawgivers as Solon or Lycurgus. Each is a legal Hercules—a collective person—carrying off the praise of exploits belonging to other men and other times.

Even in the early and dark ages of Grecian legislation, we may learn to trace events as they emanate partly from human will, partly from overruling causes, local or general;—may remark the changes effected in law by intercourse with strangers, increase of wealth, inventions and discoveries in arts and sciences, division of labour, the propagation of new opinions maintained by leading spirits, and the shocks of external attack or internal revolution.

The later laws of the Grecian states,—especially the laws of Athens,—have strong claims upon the attention of the scholar; but it cannot be denied that they are too imperfectly known in some cases, and that in others the bustling action is too rapid and of too local an interest, to render them proper subjects of detailed research in an Article necessarily so limited in extent as the present.

That a people so many-sided, so æthereal, so full of native fire, so abounding in the inspiration of genius as the Greeks—a people never equalled in painting and sculpture—wonderfully proficient in music, history, oratory, poetry—profound as well as acute in metaphysical research, and passionately fond of litigation—should not have displayed, in the cultivation of jurisprudence, remarkable ingenuity and refinement could not have been anticipated, and is, in fact, contradicted by extant specimens of Grecian legislation. Yet, gifted as they were with talents the most diversified, keenly alive to every allurement of sense, easily impressed with every form of beauty,—nay, often enthusiastic in their admiration of virtuous sentiments and actions,—the Greeks were not distinguished by a simple, diligent, and permanent worship of justice. They were distracted by too many exciting pursuits to develop calmly and patiently the principles of private law. Faction was their element; and the legislation of victorious faction was tinged with the bitterness of party spirit. Ambition, fear, revenge—the consequences

Law.

Law. of party spirit—were excited to frenzy by the rhetorician and the demagogue, and often unduly agitated lawgivers, jurors, and magistrates.

Of the private law of the Athenians, our knowledge is principally derived from the remains of the orators; from the explanations of lexicographers, as Harpocration and Pollux; and from the incidental notices of ancient scholiasts. From the time that Greece had attained its highest civilization, it did not remain long enough independent to foster a distinct class of lawyers, devoting all their powers to the cultivation of their profession, and seeking, like the Roman juriconsults, through a succession of ages, to give symmetry to the body of law, to establish sound principles, to solve doubts, to reconcile cases of apparent conflict, and to follow legal rules into their remotest deductions. Even with the laws of Athens our acquaintance is fragmentary; not a single systematic or institutional work upon Athenian jurisprudence having come down to us.

Those who desire to study the existing fragments of Athenian law, in a collected form, may consult the following works:—

Desiderii Heraldi Quæstionum Quotidianarum Tractatus; ejusdem Observationes ad Jus Atticum et Romanum cum Salmasii Defensionibus (Paris, 1650).

Jo. Meursii, *Themis Attica* (Traj. ad Rhen. 1685; 4to.).

S. Petiti, *Leges Atticæ*, with the observations of Wesseling and others (Lug. Bat. 1741; folio); being the third volume of the collection entitled *Jurisprudentia Romana et Attica*. Sam. Petit is often inaccurate.

Potter's *Antiquities of Greece*,—a work well known and esteemed in this country,—is learned and useful.

Platner (Ed.), *Der Prozess und die Klagen bei den Attikern* (2 Bände 8vo.; Darmstadt, 1824-5.)

Meier (M. H. E.) and Schömann (G. F.), *Der Attische Prozess* (8vo.; Halle, 1824.) This is the most valuable treatise which has yet been written on the subject of Attic Procedure.

The English reader who desires to investigate the public law and political institutions of the Grecian States, as treated of in modern works, will consult the *Histories* of Gillies, Mitford, and Thirlwall; Clinton's *Fasti Hellenici*; and the treatises, which have been translated into English of Heeren, Müller, Boeckh, C. F. Hermann, and Wachsmuth.

The Articles upon the Laws of Ancient Greece signed with the initials C. R. K. (Charles Rann Kennedy), in *The Dictionary of Greek and Roman Antiquities*, edited by Dr. Smith, and lately published by Taylor and Walton, are exceedingly accurate, and contain the fruit of much original research. They have the further advantage of directing the reader to the best modern sources of information.

Sect. 2. *Advantages of the Study of Roman Law.*

267. The institutions of the ancient Grecian States bear a fraternal resemblance to each other, and to the early law of ancient Rome. But the history of Roman law possesses an interest far less temporary and local. From the length of time during which the empire of Rome continued, from the intrinsic merits of the Roman system, from its subsisting effects upon the institutions of the modern world, from its connexion even with our own jurisprudence, and its utility as an object of comparison and contrast, the Civil Law (as the Imperial Law of Rome has been called by way of

eminence) deserves to be studied with peculiar diligence; but in order fully to understand the Civil Law or the Imperial Law of Rome, it is necessary to trace back to its origin the earlier history of Roman jurisprudence.

In this Chapter,—which is intended to recommend the study of Roman law to English readers,—we shall examine it as affording a type of that blending of popular and technical elements—that progress from the religious, the poetical, and the symbolical to the artificial and practical,—and of that decline of living energy when the period of active growth is ended, which, according to Savigny,* mark the course of all systems of law; we shall then view it in its historic bearing on our own law as administered in some of our various courts of justice; we shall point out its importance in the illustration of Roman history and philology, and we shall conclude by attempting briefly to discriminate some of its characteristic merits and defects.

Experience seems to shew that, in the growth of Roman law legal systems, the combined result of necessary causes and of the arbitrary exertions of the human will is manifested in a deviation from uniformity which is not unlimited; and Rome endured as a living empire for so many ages that, in following the origin, progress, and vicissitudes of her legal institutions, we are presented, on a great scale, with a pattern (if any where such a pattern can be found) of average development. We see law in its infancy, youth, manhood, and decline. We are not allowed indeed to witness its very birth. That is shrouded in the darkness of antiquity.

There can be no doubt that the greater part of the early Roman law, not relating to legal procedure, but regulating the primary rights subsisting between man and man, was first observed as custom.

Slight and almost imperceptible is the boundary between mere custom and law. The origin of custom, as distinguished from law, is not traceable to an individual or to a body of men. It seems to arise spontaneously in the minds of multitudes. Mere custom lives on without taking notice of its own existence. It has no future aim. It exercises no active powers. In a system regulated by law there is consciousness of volition: a conception of a governing power,—a rational standard to which it is felt that human conduct ought to conform in time to come. Custom passes into law. When a custom begins to be associated with the feeling of right, when the omission of its observance is felt as an unjust disappointment of well-founded expectations, and when those who, either by usurpation or by consent, exercise authority in a community, begin to employ their force in punishing the violation of such custom,—the custom is already converted into a law. The execution of laws, thus originating out of custom, and sanctioned by general feeling, adds to the authority of the magistrate, and gives him the power of imposing as legal commands the dictates of his own will, though in part morally unjust or socially inconvenient. The legality of the better is imparted to the worse. However much the notions of legality and justice may become separated in the progress of events, they are originally closely connected. The arbitrary commands of a despot, not respecting to a considerable extent the customary usages of a people, and not coinciding with their feelings of justice, might be obeyed from fear, but would never be regarded as legal.

* See his celebrated *Essay on the Vocation of our Age for Jurisprudence*, translated by Mr. Hayward.

Law.

Perhaps in the earliest period of Roman jurisprudence there were several branches of law which derived their existence immediately from the creation of legislators without any previous existence in the form of custom. In early law, there is often much that is palpably arbitrary, and there is much which evinces by its unity and system the invention of some single scientific head. There are several gradations from that order which is created at once,—springing like Minerva from the brain of Jove,—to the order which is the result of the slow victory of the more reasonable among conflicting customs. To distinguish by internal evidence the creature of direct legislation from the creature of custom, and to determine the departments in which one or the other predominates, is an interesting and instructive speculation, for which the early history of Roman law affords ample scope.

Religious
character
of early
Roman
law.

In the early Roman polity, so far as it appears to have been derived from the Etruscans, (*see Festus v. Rituales*), may be observed that close connection of law with *religious* solemnity which almost invariably characterizes the legislation of ancient people. Among the Romans, as among almost all ancient people, the dark doubts which, in the absence of supernatural revelation, are felt as to the future and the past; the belief of superhuman powers, and the irrepressible longing for the unknown and the infinite, were connected with worldly affairs, and made the instruments of action on the hopes and the fears of men.

Symbolical
character
of Roman
law.

Ceremonies of different kinds, varying with the genius of the people, are always found in early laws. Of these, some are obviously symbolical; some, from the commencement, are more abstruse, and live on in practice when their inner meaning is forgotten, or known only to antiquarians and lawyers. Rome presented no exception to this rule. Among the early Roman juriconsults, one of the greatest mysteries of the legal craft was the preservation and due application of the more ancient symbolical forms. These were employed partly to excite the attention and impress the memory; but there was a necessity for their existence in the same mental constitution, which, without thought of utility, fills the vocabulary of primitive people with metaphor, and their style with parable. Most legal forms, however they may differ in felicity of imagery, are originally a natural drama. In later times, artificial science and the prose of busy worldliness may alter their character and deaden their spirit, but they often still retain a remnant of their original nature. They have two of the three great elements of poetry. They are "simple and sensuous."

Introduc-
tion of the
technical
element.

In early Rome, though the customs or laws which regulated the private rights of individuals, anterior to and independent of the rights connected with legal procedure, were known to the people at large; yet there always existed a *technical* branch of law, unknown to the people at large, regulating legal procedure and those secondary rights which are connected with it. Barbarous and oppressive in many particulars as the early Roman Law of Procedure undoubtedly was, it had the effect of bringing into existence a body of professional lawyers, and this consequence in the sequel proved highly conducive to the improvement of private law. When the affairs of life became complicated: when commerce created new wants, and reflection gave birth to new arts, the common people were no longer able to master the increasing store of legal knowledge relating

even to their own private rights, and were obliged to resort for the resolution of doubts and difficulties to the technical juriconsult. The opinions of a class of men, qualified by education and experience to judge correctly on the questions proposed to them, had, as might have been expected, considerable influence on the development of private law. The decisions of the prætor felt this influence. It was manifested in his edict. It was shewn in the systematic and logical form which distinguished the institutional treatises written by lawyers. And it was not alone in form and symmetry that the law was improved. The Roman mind seems to have been always sensible to the claims of justice; and the rigid doctrines of the Stoic philosophy which was professed by many of the most eminent jurists contributed to give an air of virtuous dignity to many of the rules admitted into practice. The learned leisure of the professional lawyers, and their forward-looking character, combined with the rarity of interference by the legislature in the regulation of private rights, were the means of saving the Roman system from that patchwork appearance which is usually presented by a system formed from time to time under the pressure of the occasion. To the great abilities, accurate reasoning, sound judgment, and correct principles of the juriconsults of the golden age of Roman law (from Cicero to Alexander Severus), we owe many of its most valuable and enduring passages. They seem to have aimed to reconcile the dictates of reason with the rigid rules of law. They taught the magistrates how to employ legal fictions, when ancient technicalities would otherwise have been too strong in a direct contest with the rising demand for reformation. Powerful dialecticians, and great masters of a clear and concise style, their genius was yet so eminently practical that they rarely descended into scholastic divisions. Leibnitz compares their writings for close logic to those of the ancient geometers. "*Ego—auctorum labores,*" says he, "*ex quibus Digestorum opus exceptum est, admiror, nec quidquam vidi, sive rationum acumen, sive dicendi nervos spectes, quod magis accedat ad mathematicorum laudem.*"* They calculated with words, and the steady use of legal terms in a fixed sense, and the studious rejection of redundancy, of ornament, occasioned a close resemblance between the diction of most of them. Their workmanship was often more valuable than the materials upon which it was employed. It was happy indeed for Roman law that it was principally in legal procedure and in relations peculiarly affecting the Roman citizen that the system was hampered by barbarisms, which the plentiful introduction of fictions could not altogether remove. In the branches of law which were sometimes designated by the terms *jus gentium*, the rules that reason and justice would dictate were usually stated with much perspicuity, and reduced into highly scientific order. It was the authority of the juriconsults which conferred upon Roman law the impress of high morality and distinguished intellect. It was the juriconsults who made it immortal. If it were only for the models of legal style and reasoning which Roman law presents, its study would be as highly desirable to the modern lawyer as is the contemplation of the master-pieces of ancient art to modern painters and sculptors.

A time came when the law was oppressed by its own weight, when the complexity of practice, the long series

Law.

* Leibnitz, *Œper*. tom. iv. pars iii. p. 254. Edit. Genev.

Law. of authoritative writings, the unwieldy bulk of express enactments, and the multitude of voluminous commentators, were sufficient to bewilder the most resolute jurist. Then came the collections of law of which the most celebrated was made under the auspices of Justinian, and has survived entire to the present day.

Phases in the history of Roman law since the time of Justinian. From the origin of the city to the legal consolidations of Justinian, the Roman law extended over a period of about thirteen centuries. The fate of the Imperial Law from the death of Justinian,—its long slumber, or rather drowsy existence, during the ascendancy of Teutonic jurisprudence; its rapidly increased vitality in the XIIth Century of the Christian era; its introduction into the legislation of modern Europe under the authority of adoption by the sovereign powers of several states, and the recent diminution of its influence as a living system on account of the codes which regulate the administration of justice in some of the continental nations; these are events of no mean importance in the history of mankind,—unparalleled in importance by any other system of law, and exhibiting phases which illustrate all other systems. Some of the reasons which make it expedient for a philological student to select a *dead language* as the subject of his investigation, and some of the motives which should guide his choice, apply, *mutatis mutandis*, to fix the attention of a scientific jurist upon the Roman law. The analogies, indeed, are many which subsist between the studies of law and language. As a man of one language can scarcely understand that language well, so a man who has studied but one legal system will be deprived of many of those suggestions and associations which comparison and contrast furnish, and, for want of their aid, will be unable to connect those disjointed fragments which otherwise would be viewed in their proper places as parts of a continuous whole. Legal systems, like plants, may differ greatly from each other, but the botanist who has watched a single noble plant through all its processes from its germination to its withering, will have acquired a species of knowledge which will usefully direct observation and suggest experiments as to the properties of other plants.

Utility of the study of Roman law to the English lawyer. We have dwelt upon the importance of carrying these views into the study of Roman law, because the English lawyer is too often contented to confine himself to the investigation of his own system apart from all others. Among the evils which arise from this exclusiveness and isolation is a want of capacity,—prevalent among English lawyers,—to comprehend the reasonings or even to understand the nomenclature which pervade continental legislation and the writings of foreign jurists. Crippled and constrained by the contemplation of a single object, the mind loses the power of free attitude and unbiassed view. This evil has not been unfelt in diplomatic controversies on disputed questions of international law; for misunderstanding and want of sympathy are occasioned by diversities in the use of language and the association of thought.

Connection between Roman and English law. The *Corpus Juris Civilis* is to the majority of English lawyers an unknown book, and yet if we were to investigate the beginnings of many doctrines which now hold undisputed place in our law, we should be obliged to own that Rome was their true birthplace. In making this statement, we would, at the same time, guard the reader against the common error of supposing that historical derivation must exist wherever there is internal resemblance. Some principles of right are

understood by all men; and if two nations prohibit theft and murder, no inference can thence be drawn as to the originality of the one and the imitation of the other. Similar circumstances among different people will produce similar laws, and here and there a resemblance may be due to accidental coincidence. Legal antiquarians, like etymologists, have often committed gross errors of criticism, by deciding upon the derivation of legal systems according to fanciful and superficial theories. We are far from asserting that any of our common law has descended to us from the time when the Romans occupied this island—when, according to the conjecture of Selden, based upon a passage of Dion Cassius (lib. lxxii. in *excerpt. Xiphilin.*), Papinian might have been heard pronouncing judgment in a British court. Beyond, perhaps, a few popular traditions, some branches of royal prerogative, and some uneffaced imitations of Roman institutions apparent in our municipal corporations, the Saxon dynasty seems to have obliterated the traces,—never probably very widely nor very deeply impressed,—of Roman jurisprudence. In the barbarous specimens of legislation due to the era of Saxon and Danish rule, the few texts of Roman law which occur appear to us to be traceable through the papal canons. How faint is the impression which even the Anglo-Saxon laws have left upon our system! We have still the local court and the local officer; and some of the rude democratical elements of judicial procedure and constitutional law have been matured into institutions of real, civilized liberty; but, happily for us, the harsh and partial regulations, savouring of original Teutonic savageness, which awarded the various penalties of crime, have passed away, and the ancient absence of all express regulation in many most important points has been supplied by the legislation of more enlightened times and more cultivated men. Of the refined yet exceedingly oppressive system of Norman feudalism,—with its *maritagium*, its aids and wardships,—which was introduced throughout England after the Conquest, as rapidly as circumstances would permit, the antecedent history is exceedingly obscure, and notwithstanding many striking analogies, it is impossible to make out that the Norman writs and pleadings had any historical connection with the Roman *formulae*, or the process which was despatched in the name of the emperor.

The history of the Roman law in this country has been treated of by Selden in his *Dissertation on Fleta*, by Dr. Duck, by Hurd in the first of his *Dialogues on the Constitution of the English Government*, and by Von Savigny in various parts of his *Geschichte des Römischen Rechts im Mittelalter*. Soon after the establishment of the school of Irnerius at Bologna, the Pandects were brought to this country by Vacarius in the reign of Stephen. All that is known of Vacarius, who was the first professor of the Civil Law at Oxford, has been collected by the late Dr. Wenck of Leipzig. The early text-writers of English law have borrowed, more or less, from Roman sources, principally through derivative channels. Scarcely anything in Glanville (who wrote in the reign of Henry II.), except the formal introduction, savours of Justinian; but large portions of the first three books of Bracton's *Treatise De Legibus Angliæ* (which appeared in the reign of Henry III.) are taken from the Institutes of Justinian, not directly, but through the medium of Azo's *Commentaries*. Whoever (as we have done) compares with Bracton the *Summa Azonis* will see that the Roman portions of the former are, for the most part,

copies or abbreviations of the latter, with occasional accommodations to existing English institutions. The English legislature, though not remarkably attached to originality, as may be seen by comparing (see Houard in his introduction to his Treatise on the *Coûtumes Anglo-Normandes*) some of our ancient laws with the earlier capitularies of the Frankish kings,—rarely, in early times, adopted the language or the principles of the Roman law. Every one has heard of the repudiation by the parliament of Merton of the doctrine of legitimation *per subsequens matrimonium*, when, to repeat an often-quoted sentence, “*Omnes comites et barones unâ voce responderunt, nolumus leges Angliæ mutari quæ hucusque usurpatæ sunt atque approbatæ.*” In this decision, it is probable that the jealousy of ecclesiastical ascendancy had much weight. The canon and civil laws were associated in idea, and the barons dreaded the introduction of a system of jurisprudence, which might have impaired the vigour of the feudal tenures, with all their lucrative incidents. Higher motives of patriotism may have mingled with prejudice and dislike. Among the best known portions of the imperial law—the only portions still known to many—were certain sentences concerning the authority of the emperor, which occupied a prominent place in the van of the Institutes and the Pandects. “*Quod principi placuit legis habet vigorem, cum, Lege Regiâ, quæ de Imperio ejus lata est, populus ei et in eum omne suum imperium et potestatem conferat.*”^{*} Bracton, by a kind of pious fraud, misinterprets, and paraphrases in an extraordinary manner, the words “*cum Lege Regiâ quæ de Imperio ejus lata est.*” “*Id est,*” says he, “*non quicquid de voluntate regis temere præsumptum est, sed quod consilio magistratuum suorum, rege auctoritatem præstante, et habitâ super hoc deliberatione et tractatu, rite definitum est.*”[†] In other words, the king’s pleasure is law; but that is the king’s pleasure which is indicated by a royal law passed in the imperial council. Other passages, equally at variance with the spirit of our constitution, which, even in early times when the limits of the prerogative were not well defined, was always adverse to autocratic monarchy,—other passages, equally requiring a decent veil or a fallacious gloss, are to be found straggling in several parts of the Imperial Law. Upon the main body of Roman Law, formed in republican times, they were mere excrescences. They did not pervade the system, but probably if the system had been partly introduced into England, occasion might have been taken gradually to broach doctrines adverse to liberty. The feeling prevalent among common lawyers, of the dangerous and slavish nature of a study with which their acquaintance was small, was fostered by the most celebrated of our early constitutional writers, Fortescue; and, for the combined reasons to which we have alluded, there was little systematic borrowing from Roman stores on the part of the parliament and the common law judges. A maxim or a rule was, ever and anon, stolen from the Institutes and the Pandects, but, as usually happens when plagiarism is committed by men whose knowledge is superficial and hastily acquired, was almost always distorted or misunderstood. The most learned civilians among our judges, as Holt, were mere amateur players with the Roman Law. Even that which was tolerably unadulterated upon its introduc-

tion was soon modified by English notions; and thus it happens that, though many phrases and expressions are shared by our common law and the civil law, there are few which are used in the same sense in both.

There are other English tribunals—of which the Admiralty and Ecclesiastical Courts are the principal—wherein the law that is administered and the manner of administering law, bear in many particulars plain marks of immediate Roman derivation. To the advocates who practise in those courts, the study of the Roman law is advantageous for reasons which do not so strongly apply to the student of common law. The advocate, in the imperial collections and the commentaries of civilians may often find the very doctrines which he is in need of for practical application: doctrines, which, from the mere circumstance of their origin, would be addressed with a shew of authority to the ears of the judge, though unaided by very particular precedents and very clear analogies, and independent of their intrinsic reasonableness. In our Common Law Courts, the civil law has no such *primâ facie* welcome, and closer proof of antecedent adoption in circumstances similar to the case in question seems to be required. In both kinds of courts, any reception of the civil law depends, according to orthodox legal theory, upon customary adoption in particular cases; but, in fact, the adoption is more specific and not so wholesale in the courts of Common Law. In the Courts of Common Law, occasions do not often arise of illustrating a doubtful question by a quotation from the Institutes, the Code, the Pandects, or the Novells. Some such questions indeed may occur. In putting a construction upon the Statutes of Distribution, for example, reference might be made, without any imputation of misplaced learning, to the 118th Novel of Justinian. Cases where the jurisdiction of the Common Law Courts and the Courts Christian is concurrent may afford opportunities for such quotation; and there are branches of mercantile law, which have been developed by Lord Mansfield and other great judges, not without attention, either immediately to Roman jurisprudence, or to foreign usage based upon rules of Roman law. Upon such subjects, a citation from the *Corpus Juris Civilis* might afford so apposite an illustration, that by a barrister of wary discretion and delicate tact it might be hazarded even in a Common Law Court, without exciting much ridicule or provoking a remonstrance from the bench.*

In an intermediate position, with respect to the civil law, between the courts of common law and the courts to which we have last alluded, is the Court of Chancery. Many of the leading doctrines of English equity, though they have been much modified in our tribunals, are manifestly taken from the collections of Justinian.

* “One day, *in banco*, a learned gentleman, who had lectured on the law, and was too much addicted to oratory, came to argue a special demurrer. ‘My client’s opponent,’ said the figurative advocate, ‘worked like a mole under ground, *clam et secretè*. His figures and law Latin only elicited an indignant grunt from the chief justice. ‘It is asserted in Aristotle’s Rhetoric’—‘I don’t want to hear what is asserted in Aristotle’s Rhetoric,’ interposed Lord Tenterden. The advocate shifted his ground, and took up, as he thought, a safe position. ‘It is laid down in the Pandects of Justinian’—‘Where are you got now?’ ‘It is a principle of the Civil Law’—‘Oh, sir!’ exclaimed the judge, with a tone and voice which, to a punster’s ear, would have abundantly justified his assertion, ‘we have nothing to do with the Civil Law in this court.’”—26 *Law Magazine*, p. 73.

* *De Constitutionibus Principum*, l. 1, pr. D. (i. 4.)

Law.

Our ancient chancellors, up to the time of Wolsey, were mostly ecclesiastics, and had not that horror of a foreign jurisprudence which distinguished some of our common lawyers,—which made Lord Coke exult in the fancied *autochthonous* character of English legislation, and praise his countrymen as legally deserving to be styled "*Penitus toto divisos orbe Britannos*." The notions of "*Forum Romanum*" and of "*Jus Prætorium*" have been generally present to the minds even of more modern chancellors; some of whom, as Lord Nottingham and Lord Hardwicke, afford indications of having studied the civil law with considerable attention. To the equity barrister, not merely for general discipline, but for the special illustration of his own department of law, we recommend an original knowledge of the *Institutes* of Justinian, and of those parts of the *Digest* which, in legal treatises on equitable subjects, are often quoted at second-hand and explained incorrectly.

Dulcius ex ipso fonte bibuntur aquæ.

Light shed
by Roman
law on Ro-
man his-
tory and
philology.

We have endeavoured to point out, without exaggeration, the connection which subsists between English and Roman law, and the extent of the benefit which an English lawyer may acquire by becoming a learned civilian. We proceed to advert shortly to the light shed by Roman law upon Roman history and philology.

Many historians have been ignorant of law; and yet there are few nations whose history can be properly written without a careful study of their jurisprudence, not only as it affects the constitution of the governing power, but as it regulates the private rights of individuals. Perhaps, of all histories, the Roman would be the most incomplete, if it did not include an account of the progress of the legal institutions of Rome. The Roman people, even more than the people of our own country, were imbued with the spirit of their laws. They were accustomed to legal solemnities, and often regarded with greater jealousy an infringement of established forms than an inroad upon their civil liberty made under cover of constitutional observance. This is particularly observable in the commencement of the reign of Augustus. The Roman child was catechized in the Twelve Tables or the Prætor's Edict; and the Roman man delighted to witness the litigious contentions of the Forum. If we examine the Roman character for the sake of discovering its most conspicuous features, we shall be led to designate it, as, in the first place, warlike, and, in the next, *legal*.

*Tu regere imperio populos, Romane, memento,
— pacisque imponere morem.*

Philosophy, fine arts, and polite literature, the Romans borrowed from the Greeks; but in the cultivation of military science, and in the development of an elaborate system of jurisprudence, they manifested something like original genius.

That legal genius which was so essential an ingredient in their lives, and those peculiar institutions which coloured all their nationality, must be duly appreciated by all who would enter into the spirit of their history. The historians and other classical writers of Rome are full of allusions to legal notions. In the Latin books which are ordinarily read in schools and colleges, many passages occur which to ordinary readers, ignorant of legal history, are either incomprehensible or wholly misinterpreted. Take, for instance, the orations of Cicero *pro Quintio* and *pro Cæcina*, and see

VOL. II.

how slightly the majority of English scholars can penetrate their sense and spirit.

Law.

Character-
istic me-
rits and de-
merits of
Roman
law.

It has been our object, in what we have said in recommendation of the study of Roman law, to give a correct and critical estimate of its real advantages without indulging in the hyperbolic panegyric which is common among those who have either devoted much time to the investigation of its niceties, or are willing to earn a cheap reputation by praising a species of learning in which there are not many able to detect their deficiency. The enduring and wide-spread authority of the Roman law, surviving the power of the Roman arms and the destruction of the Roman empire, is a proof of its great merit, and is a memorable example of the ascendancy of reason over brute force. It had also great defects. The marks of its narrow and barbarous origin were never entirely effaced; and the indirect attempts to efface them were the cause of excessive technicality and over-subtle refinement. In the style of the later Imperial constitutions, there is an Asiatic pomp and tumour which contrasts unfavourably with the vigorous conciseness of an earlier age. Even the real improvements of later times disturbed the symmetry of the ancient system, which, with elaborate logical consistency, harmonized and connected the evil and the good.

No enlightened legislator in modern times would resort to the tortuous fictions,—the exclusive distinctions in favour of citizens,—the exorbitant powers of the father, husband, and master,—the want of protection against the abuse of authority in the government of dependencies,—the rudeness in the administration of criminal justice, which characterized even the brightest periods of Roman jurisprudence. The jurist of modern times, on the other hand, would be rewarded by an investigation of the Roman doctrines of successions, the estimation of damages, the determination of the *onus probandi*, the principles of interpretation, the analysis of obligations, the nature of the events by which rights begin, are transferred, and ended. Even where the subject is worthless, the manner in which it is handled by a Gaius or an Ulpian affords a lesson rich in practical use.

Sect. 3. *On the Study of the Origin and Changes of the Legal System of Ancient Rome.*

268. The most improving mode of studying Roman law is to regard it not merely in one of its several phases, but to investigate its commencement and trace its changes. To English scholars and jurists in particular, an historical study of Roman law, rather than a technical study of the compilations of Justinian, is to be recommended. We proceed to point out some of the authorities which may be consulted with advantage, and to give some account of the literature of Roman law.

Leibnitz seems to have been the first who divided the history of law into *internal* and *external*. Though these two parts are not strictly separable, yet most modern writers have adopted the distinction, using the words in a sense rather different from that in which they were originally employed by Leibnitz.

"Historical jurisprudence," says Leibnitz, "is either internal or external. The former enters the very substance of jurisprudence. The latter is only an auxiliary and support. The internal history of law gives an account of the laws themselves of various states. In

Division of
the history
of law into

Law.

my opinion a more special enumeration is still wanted. In Roman law, for example, we want a statement of the changes made by each tribune through *plebiscita*, by each consul through *senatus consulta*, by each prætor through his edicts, by each emperor through his constitutions, until the system grew into its present form.* To explain the meaning now usually attributed to the distinction:—External history treats of the modes by which laws come into existence, and of the manner in which the science of law has been from time to time cultivated. It explains the political events which have had an influence upon the progress of legislation, and gives a chronological account of laws, lawgivers, and legal works. It is sometimes divided into two parts: (a) history of the sources; (b) history of the literature.

No history can do all that external legal history is required to do, without adverting to the contents of the laws themselves; but a history, the *principal object* of which is to trace the variations of doctrines of law—to consider, for instance, the different rules prevailing at different times with respect to property, judicial organization, procedure, penal law, the relations of personal *status*, and so forth—is called an *internal history*.

It is obvious that a history, in order to be complete, ought not to confine its views either to the *sources* of law—that is to say, the modes by which law comes into existence,—or to the *contents* of law—the variations which the propositions and conceptions of law from time to time undergo. A complete history of Roman law must be both external and internal. It will direct attention not only to the constitutional changes in the legislature and the magistracy, and to the dry names of laws and lawgivers and legal works, but to the progressive development of the social state of the Romans, and to the general spirit of those institutions, civil and political, which affected the character of their public and private life. How inseparable, in the reality of things, are the subjects of external and internal history, may be rendered plain by considering that as the habits and thoughts of people give rise to actions and political events which produce changes in legislation, so, alternately, do the contents of new laws give rise to new thoughts and habits. External and internal history resemble those geometrical figures *which circumscribe each other*.

Necessary
imperfec-
tion of the
History of
Roman
law.

In a history of law like the Roman, we must expect to find many absolute gaps, and many doubtful questions. The most diligent research has left many things obscure and unelucidated. We may meet with a statement, for instance, that a law has existed, without being told when, or how long. This happens frequently when we have recourse to writers not professionally legal. Sometimes, intentional alterations and interpolations have been made, without notice, by subsequent compilers.

Different writers, in treating of the history of law, have

* "*Jurisprudentia historica est vel interna vel externa: illa ipsam jurisprudentiæ substantiam ingreditur: hæc adminiculum tantum et requisitum. Historia juris interna est, quæ variarum rerum publicarum jura recenset; desidero tamen specialem recensionem, quid a quolibet tribuno per plebiscita, aut a quolibet consule per senatus consulta, prætorum per edicta, et imperatore per constitutiones ordine innovatum sit, donec in hanc formam jus Romanum crevit.*" Leibnitz, *Nova Methodus discendi docendæque Jurisprudentiæ*, pars ii. sec. 29.
